Important Ecological Factors ESA 12 is identified between KP 291.9 and KP 299.5 for eleven globally-threatened plant species (*Centaurea schischkinii, Thlaspi cilicicum, Elymus sosnowskyi, Ballota rotundifolia, Thymus pectinatus var. pectinatus, Thymus canoviridis, Onobyrchis araxina, Fritillaria alburyana, Consolida cornuta, Scrophularia versicolor* and *Pimpinella anisetum*).The ESA continues on to the next map (Map 17B). The IUCN status for these species are given in Table 5.20, Section 5. At KP 291.6, 8 Pale Rock Sparrow (nationally-threatened) were recorded. Four nationally-threatened birds (Shoveler 12, Teal 4, Pintail 1, and Citrine Wagtail 1) were recorded at the lake located c. 1.8km north of the route within the Erzurum Marshes IBA (see Environmental Impact Table 17 and Map 17B for details). The protection status for these species are given in Table 5.21, Section 5.	Habitat destruction of plain steppe may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 12. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW.	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Environmental Impact Table 16 (Maps 16A and 16B) (KPs 278.7 – 297.8): Pasinler Plain and Kargapazari Mountain area, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Pale Rock Sparrow.	
Noise			
An Industrial Area (KPs 279.3 – 281.6) is located directly adjacent to the pipeline route. Commercial properties such as offices may be sensitive to noise during pipeline construction. However, these properties are generally considered to be less sensitive to noise than residential dwellings and schools etc.	Noise impacts are expected to occur at properties located adjacent to the Pipeline works during: • soil stripping; • welding/lowering; • backfilling; • bending; • trenching. During works associated with the railroad crossing in this area, noise impacts will also result from excavation and sheet-piling.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see	**MODERATE IMPACT** Due to the proximity of the site to the Pipeline, noise impacts are expected to occur at commercial properties during each phase of construction, despite the use of noise mitigation measures. Where possible, mobile noise barriers will also be used to screen plant.

Environmental Impact Table 16 (Maps 16A and 16B) (KPs 278.7 – 297.8): Pasinler Plain and Kargapazari Mountain area, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Appendix C4).	
Archaeology and Cultural Heritage			
Tetikom Mound (2nd Degree Site*) is situated south-west of Tetikom Hill, to the north of the route. The settlement mound displays Late Calcolithic, Early Bronze Age and Iron Age (Urartian) cultural layers. Illegal excavation pits and regular stone blocks are visible on the surface. The mound was damaged during the construction of NGP. * This site has not yet been registered by the MoC and is provisionally assigned this classification. Tetikom mound has been proposed for registration by the regiona preservation council	Potential for direct impact at this site during pipeline construction through ground disturbance. In addition, indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	The site will be fenced throughout the construction period. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Impacts will be limited to the temporary disturbance of the site setting and peripheral features.
The fiollowing have been proposed for registration by the regional preservation council: (i) Military shelters 1; (ii) Military shelters 2; (iii) Tetikom Hill			

Social Impact Table 16 (Map 16C) (KPs 278.7 – 297.8): Pasinler Plain and Kargapazari Mountain area, Erzurum Province

Map 16: PROJECT INFORMATION

There is one pump station (PT2) and one primary construction camp in the area (on the junction of maps 15 & 16). There is no block valve station.
There were two options considered for PT2, Option 2 has been selected. It requires 16.94ha and is on privately owned land.

Map 16: MAP HIGHLIGHTS

- Unclassified roads link local settlements. National highway bisects pipeline.
- Railroad link from industrial area, bisecting pipeline once, and coming within a few meters of it a second time, running broadly parallel to pipeline.
- Pipeline passes through the Kargapazari Mountain.
- The pipeline crosses the Hamam creek.
- There are rainfed crops and irrigated crops cultivated.

Map 16: SURVEYED AND IMPACTED SETTLEMENTS

- ***Impacted:*** 16 settlements on this map will be directly impacted by the pipeline project: 13 will have land intersected by the proposed pipeline (L) (Korucuk, Nenehatun, Pusudere, Golcigez, Buyuktuy, Kaplicalar, Pasabey, Yukari Cakmak, Cicekli, Cogender, Agcalar, Ovakoy, Uzunahmet). None are within 5km of a construction camp (C); and seven are within 5km of a pump station (Yukari Cakmak, Cicekli, Cogender, Agcalar, Ovakoy, Bingol, Yittigasi) (P). None are within 2km of a block valve station (B) or 500m of the pipeline route (D). Settlements impacted by traffic have not yet been identified. One settlement is downstream of a creek crossing (Buyuktuy is 2.5km downstream of the Hamam creek) (R).

- ***Surveyed:*** one settlement (Yukari Cakmak) was surveyed in the field (S) and 11 settlements were surveyed by telephone (T). Settlements within 5km of the pump station and construction camp were surveyed. In addition, consultation meetings were held with settlements within 5km of pump station and the construction camp.
- ***Not surveyed:*** Ezirmik (1.57km north of pipeline), Kaplicaler, Pasabey
- ***Not on map:*** Pasabey, Cogender, Agcalar, Ovakoy, Bingol

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Korucuk (L) (T)			
• ***Demographics:*** 350 inhabitants. • ***Safety****:* the centre of the settlement is 1.1km from pipeline, the nearest house in the settlement is 1km from the pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive. • ***Land ownership & use:*** 70% of land is privately owned by the local residents. No grazing occurs. Seasonal irrigation is undertaken.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be

Social Impact Table 16 (Map 16C) (KPs 278.7 – 297.8): Pasinler Plain and Kargapazari Mountain area, Erzurum Province

• ***Settlement livelihood:*** agriculture, construction, trade and local government are the main sources of livelihood. • ***Accessibility:*** 16km to Pasinler district centre. The settlement is accessible all year. • ***Information provision:*** 95% of the population is literate. TV and the newspaper are the best information provision techniques. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. • ***Settlement problems:*** poor roads and the need for a Muhtar room.			compensated.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Pusudere (L) (T)			
• ***Demographics:*** 228 inhabitants, with seasonal migration of 1%. • ***Safety****:* the centre of the settlement is situated 1.35km from pipeline and the nearest house in the settlement is 1.15km from the pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive. • ***Land ownership & use:*** 90% of land is privately owned by the local residents. Seasonal grazing and irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture, forestry, construction, trade and local government are the main sources of livelihood. • ***Accessibility:*** 22km to district centre. The settlement is accessible all year round. • ***Information provision:*** The best information provision tools include TV, the newspaper and via family members. • ***Environmental & cultural sites:*** park, forest. • ***Infrastructure:*** piped water is available, however its supply is irregular. An artesian well provides an alternative water source. • ***Settlement problems:*** unemployment, poor access to water and low income.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.

Social Impact Table 16 (Map 16C) (KPs 278.7 – 297.8): Pasinler Plain and Kargapazari Mountain area, Erzurum Province

	Construction hazards: animals Trench poses safety hazard for livestock.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.
	Forest Loss of a resource used by settlements. Increased expenditure on other fuel sources.	If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure.	**Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.
	Accessibility of information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Golcigez (L) (T)			
• ***Demographics:*** 131 inhabitants with seasonal migration of 5%. • ***Safety:*** the centre of the settlement is 4.6km from pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations	Contractor will **consult** with authorities to determine maximum acceptable time	**If irrigation water is disrupted** longer than time considered acceptable by

Environmental Impact Table 17 (Maps 17A and 17B) (KPs 297.8 – 316.7): Erzurum Plain, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
In this route section soils comprise Mesic Coarse-loamy to Coarse-silty Xerochrepts.	Soil related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Other potential impacts include: • soil erosion; • sediment yield; • reduced soil productivity; • contaminated soils; • waterlogged soils.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.

Environmental Impact Table 17 (Maps 17A and 17B) (KPs 297.8 – 316.7): Erzurum Plain, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Support equipment on moveable mats. • Avoid freshly irrigated soils.	
Landscape and Visual			
Here, the route descends onto the broad, flat, plain north of Erzurum. This was formerly marshland and some still remains, but most has been drained and improved to intensive irrigated agriculture, primarily cereals. Concrete-lined trapezoidal canals convey water east to west across the surface, with distribution canals near Cayirtepe and Beypinari. City edge development, settlements, a major new highway, and the airport all contribute to the urban-edge character of the area. A number of large trees are present. The landscape lacks particular merit throughout this section. Although much of the RoW of the natural gas pipeline has been incorporated into agricultural fields and has limited visual impact, there are sections that have not, which are visually intrusive, especially where close to the highway. BVS-016 will be located at KP 300.0 on cultivated land. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 50m in length.	Generally there will be a potential for low and short-term construction-related visual impacts, however, visual impacts of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and	**INDIRECT POSITIVE IMPACT** Landscape is considered resilient to change due to its existing depleted state. Any commensurate enhancements of the degraded NGP alignment will result in a net improvement to the landscape.

Environmental Impact Table 17 (Maps 17A and 17B) (KPs 297.8 – 316.7): Erzurum Plain, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).	
Groundwater			
The majority of the route passes over the Erzurum Plain, over the confined aquifer. Approximately 2.3km passes over the unconfined aquifer. Water samples were taken from four wells located: • 580m east of route (KPs 303.6 – 309.8) at Well Site No.5 (Dadas K23); • 1.8km east of route (KPs 303.6 – 309.8) at Well Site No.6 (Ciftlik K-5); • 2.1 km east of route (KPs 303.6 – 309.8) at Well Site No.7 (Ciftlik K-13); • 660m east of route (KPs 309.8 – 317.1) at Well Site No.8 (Beypinari Settlement - potable water well). Sample results indicate that groundwater quality at the Dadas K23, Ciftlik K-5 and Beypinari Settlement wells is Class II and groundwater at Ciftlik K-13 is Class III.	Potential for moderate and localised impacts to groundwater quality from construction activities.	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including: • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	**MINOR IMPACT** With the application of specified mitigation measures described, only minor impacts are expected to occur, which will be short-term in nature.
Ecology			
Protected Areas The pipeline passes through the Erzurum Plain Important Bird Area (IBA) between for a total length of c. 1.5km.Three areas of the Erzurum Plain - Kosemehmet Marshes (1,000 ha), and Sitavuk and Corak Marshes (together 2,300 ha seasonally) - comprise the IBA (no statutory protection status). Kosemehmet Marshes in the east comprise extensive areas of brackish clay grasslands surrounding a series of small lakes and springheads. Flower-rich hand-cut hay meadows occur near the	See Potential Impacts below.	See Mitigation Measures below.	See Residual Impacts below. There will be no affect on the protection status of the IBA.

Environmental Impact Table 17 (Maps 17A and 17B) (KPs 297.8 – 316.7): Erzurum Plain, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
settlements, but many of these have been ploughed in recent years. Sitavuk and Corak Marshes, to the western part of the plain, are seasonal marshes surrounded by extensive arable and grasslands. The site qualifies for IBA status for its 15 breeding pairs of Common Crane (*Grus grus*) and during migration periods for significant numbers of White-winged Black Tern (*Childonias leucopterus*) (c.15,000) and Ruddy Shelduck (*Tadorna ferruginea*) (max. 1,500).			
Important Ecological Factors The route continues to cross ESA 12 (see Environmental Impact Table 16 and Map 16B for description). Three globally-threatened plant species, (*Pulicaria armena, Hesperis schischkinii* and *Onobrychis araxina*),occur between KP 301.3 and KP 302.7. ESA 13 is identified for these species. The IUCN status for these species are given in Table 5.20, Section 5. Erzurum Plain was once an extensive area of seasonally-flooded marshes and grasslands, but is now much reduced through drainage and reclamation for agriculture and development. A few shallow pools still remain. Despite significant degradation, it still supports good numbers of waterbirds including at least eleven nationally-threatened species. Totals counted on 14-17.06.2001 include - Pintail 1; Teal 4; Garganey 3; Shoveler 12; Black Kite 3; Marsh Harrier 6; Common Crane 2; White-winged Black Tern 4; Long-eared Owl 1; Citrine Wagtail 1; and Whinchat 5. Also present were Night Heron 7; Montagu's Harrier 6; Steppe Eagle1; Black-winged Stilt 40; Lapwing 28; Green Sandpiper 2; Wood Sandpiper 1; Redshank several; Red-necked Phalarope 1; Slender-billed Gull 1; Yellow Wagtail 1; Black-headed Wagtail 70; and Sedge Warbler 1. The protection status for these species are given in Table 5.21, Section 5.	Habitat destruction of wet meadows may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 13. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. • protect the wet meadow through the whole of this ESA from	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Environmental Impact Table 17 (Maps 17A and 17B) (KPs 297.8 – 316.7): Erzurum Plain, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		heavy equipment by moveable equipment mats plates. The nationally-threatened bird species within the Erzurum Plain IBA utilise a wide variety of habitats from reedbeds (Pintail, Common Crane, etc) to Shrub (Whinchat, etc) to mature woodland (Long Eared Owl). As such, all vegetation clearance throughout this area will be undertaken between August and March, thereby avoiding the critical bird breeding season. Areas of reeds and dense vegetation will be placed out of bounds for construction workers.	
Archaeology and Cultural Heritage			
The route passes through three archaeological sites: • Tasmasor Area (2nd Degree Site*) – southern part of this site is crossed by the route at the beginning of this section. This site has already been disturbed during construction of Iran-Turkey Natural Gas Pipeline. • Cayirca-Beypinari (2nd Degree Site*) – flat settlement. No architectural remains were observed. • Beypinari-Kahramanlar (2nd Degree Site*) – flat settlement. No architectural remains were observed. The majority of this site lies on the following map and is therefore discussed in Environmental Impact Table 18 (see Map 18A). Ortaduzu Settlement is a flat settlement located within the 100m Corridor to the south of the route but is not crossed.	Tasmasor Area, Cayirca-Beypinari settlement and Ortaduzu settlement will be directly impacted and suffer ground disturbance during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of these sites.	The extent of the Tasmasor Area site will be investigated during further field surveys prior to construction. This will determine the need for detailed surface research and/or rescue excavations at this site. Further investigation will be undertaken prior to construction to identify a safe route through Tasmasor Area and Cayirca-Beypinari sites. Specific mitigation to be developed following site investigations.	**MODERATE TO MINOR IMPACTS** Residual impacts cannot be determined precisely for the Tasmasor Area at this stage since the extent of this site is unknown. Archaeological investigations prior to construction will establish the full extent of the site. However, the Tasmasor Area has been already disturbed during construction of the gas pipeline and full reinstatement during construction of the BTC

Environmental Impact Table 17 (Maps 17A and 17B) (KPs 297.8 – 316.7): Erzurum Plain, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
* These sites have not yet been registered by the MoC and are provisionally assigned these classifications. Ortaduzu settlement, Cayirca-Beypinari and Beypinari-Kahramanlar have been proposed for registration by the regional preservation council		The pipeline has been re-routed to avoid impacts to the Ortaduzu settlement. This site will also be fenced. The construction Contractor will adhere to the requirements of the Cultural Heritage Management Plan during construction through these sites.	Pipeline may provide the potential for a positive impact and improve the setting of the site. **MODERATE TO MINOR IMPACTS** Residual impacts cannot be determined precisely for Cayirca-Beypinari settlement at this stage and will be subject to further investigation prior to construction. However as investigations are expected to find a safe route through this site, the ultimate scale of impact is likely to be minor. **MINOR IMPACTS** Assuming the site is fenced, impacts will be limited to the temporary disturbance of the setting of Ortaduzu settlement and its peripheral features.

Social Impact Table 17 (Map 17C) (KPs 297.79 – 316.77): Erzurum Plain, Erzurum Province

Map 17: PROJECT INFORMATION			
There are no pump stations or construction camps in the area. There is one block valve station.			
Map 17: MAP HIGHLIGHTS			
• The pipeline crosses the Erzurum Plain is an important bird area and Tasmasor Area, an archaeological site. • Unclassified roads link local settlements. • Major town of Erzurum and airport in the area. • The pipeline crosses the Delicay creek. • The pipeline route crosses four land uses, rain fed agriculture, irrigated agriculture, pasture and non agricultural land. • Concrete canals carry water east to west across the surface.			
Map 17: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** 10 settlements on this map will be directly impacted by the pipeline project: they all have land in the intersected by the proposed pipeline (Cayirtepe, Ortaduzu, Mulk, Caylica, Soguk Cermik, Seyh, Dadas, Yesilova, Altinbulak, Beypinari). Two are within 500m of the pipeline route (L) (Beypinari and Cayirtepe). One is within 2km of the block valve station (B) (Cayirtepe). None are within 5km of a construction camp (C) or pump station (P). Settlements impacted by traffic have not yet been identified. No settlements are downstream of a river/ creek crossing (R). • ***Surveyed:*** Three settlements (Cayirtepe, Sogucak, Beypinari) were surveyed in the field (S) and eight settlements were surveyed by telephone (T).			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Cayirtepe (L) (B) (S)			
• ***Demographics:*** 1450 inhabitants with 190 households. ***Safety:*** the centre of the settlement is 750m from pipeline, the nearest house in the settlement is 450m from the pipeline. • ***Health:*** lack of sewerage system with health implications. • ***Disputes:*** over natural resources, economic. No serious tensions between different ethnic groups. • ***Project attitude:*** positive, however there is concern about potential dust arising from construction damaging potato crops and cereals, and some concern about the cultural differences between locals and workers coming from elsewhere. Local residents want workers to be recruited from Erzurum. Also concerned that pipeline must not pass through cemetery. Natural gas pipeline left wires everywhere, hurting	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 17 (Map 17C) (KPs 297.79 – 316.77): Erzurum Plain, Erzurum Province

children. It also damaged land and produce. There was incomplete reinstatement of land, damage to irrigation channels, and to roads. Expropriation payments were less than the amount spent by local residents on reinstatement of their lands. • ***Land ownership & use:*** 97% of land is privately owned by the local residents. • ***Settlement livelihood:*** main economic activities are agriculture (grain/cereals, sugar beet, fruit trees, potatoes) and animal husbandry for the production of milk. Also bee keeping (three households produce honey), education, local government, transport and trade. In addition, residents of Cayirtepe rely on cockfighting and selling pigeons as an additional source of income. • ***Availability & skills:*** there is pipeline experience. Heavy machine operators, food service, heavy vehicle operators, mechanics, tree fellers, drivers, security personnel and welders are available. 60% of those interviewed would accept a temporary job working on the pipeline construction. • ***Accessibility:*** 127km to Erzurum provincial centre and 8km to Erzurum district centre. • ***Information provision:*** 60% of the population is literate. TV and the telephone are the best information provision tools. • ***Environmental & cultural sites:*** a mausoleum / cemetery. The tomb of Cobandede is also in the area. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. There is electricity supply, however no sewerage or waste systems. • ***Services:*** there is no primary school and no health facilities. • ***Settlement problems:*** lack of water, education, poor health conditions, poor sewerage system leading to disease, and the need for more afforestation.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Bees*** Disturbance of any stationary hives located within 300m of the route.	construction work. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee

Social Impact Table 17 (Map 17C) (KPs 297.79 – 316.77): Erzurum Plain, Erzurum Province

		must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Accessibility of information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Skills & resources Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials.	**Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints.	**Potential positive benefits** to local settlements.
	Block Valve Station See EIA tables and Overview of the Land Acquisition Process in Appendix C9		

Social Impact Table 17 (Map 17C) (KPs 297.79 – 316.77): Erzurum Plain, Erzurum Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Sogucak (L) **(S)**			
• ***Demographics:*** 900 inhabitants with 145 households. Migration to metropolitan areas of Erzurum, Bursa and Istanbul is occurring. • ***Safety****:* settlement is situated 1.26km from pipeline. • ***Health:*** water from canals makes people sick; and local residents have constructed their own sewer system that passes through the settlement and consists of open water ducts which attract a huge numbers of flies. Earthquake prone area. There is a local spring that is believed to have a curing affect for urethra diseases. • ***Disputes:*** strangers not particularly welcome in settlement. • ***Project attitude:*** mixed, largely negative, as settlement has experienced three previous expropriations: NATO pipeline, auto industrial district and natural gas pipeline. Local residents are frustrated over low expropriation payments, and the fact that they had to spend these payments on reinstating their lands. Also, local residents now have to walk 500m around a road damaged by the natural gas pipeline construction. • ***Land ownership & use:*** most holdings are small-sized lands. 86% of land is privately owned by the local residents. • ***Settlement livelihood:*** main economic activity is working at nearby industrial site, or in local government. A low level of agriculture (grain & sugar beet) and animal husbandry is undertaken. Small sized farming is the dominant form. In addition, construction, transport, trade and education activities are undertaken. • ***Availability & skills:*** 60% of those interviewed would accept temporary employment on the pipeline construction. • ***Accessibility:*** 6.4km to Erzurum district centre. The settlement is located very close to a main road, and to an industrial site. • ***Information provision:*** 80% of the population is literate. TV and the telephone are the best local information provision tools. • ***Irrigation:*** natural water canals are highly contaminated and are not used for irrigation purposes. This is because the sewerage system is	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Conservative settlement*** Construction workers are more likely to offend inhabitants.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. **Construction workers to be remind**ed of the importance of appropriate	**Potential for accidents involving livestock.** Financial compensation will be given. undertaken. • ***Settlement livelihood:*** agriculture, tourism • ***Accessibility:*** The settlement is accessible all year. • ***Information provision:*** 90% of the population is literate. • ***Infrastructure:*** piped water is available, however supply is irregular. An artesian well provides an alternative water source. • ***Settlement problems:*** poor health conditions, poor sewerage system and low incomes.		settlement to be immediately warned and alternative sources of water to be provided.	
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Beypinari (L) (D) (S)			
• ***Demographics:*** 672 inhabitants with 100 households. • ***Safety:*** the centre of the settlement is situated 700m from pipeline and the nearest house in the settlement is 300m from the pipeline. • ***Disputes:*** economic causes are the main source of disputes. • ***Project attitude:*** mixed, but largely negative. The natural gas pipeline damaged land and pasture (lands were not reinstated, mud overflow which affected harvests, stock grazing on damaged pastures affected). This was not compensated. In addition, construction cut and blocked water supplied from the mountains, and after construction works, lands turned into swamps. Kurdish people from southeastern Turkey were employed rather than unemployed locals. After paying lawyers fees, little money remaining from compensation. 73% of those interviewed would accept a temporary job working on the pipeline construction.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.
• ***Land ownership & use:*** 65% of land is privately owned by the local residents and 20% is communally owned. Seasonal grazing occurs. There is no irrigation. • ***Settlement livelihood:*** main economic activities are agriculture (predominantly cereals but also vegetables and herbs) and animal husbandry. In addition, manufacturing, construction, trade and education are undertaken. Milk production is also a significant economic activity. Four households work as civil servants in	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards:***	**Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be	**Any additional damage will be compensated for.** **Potential for accidents**

Social Impact Table 17 (Map 17C) (KPs 297.79 – 316.77): Erzurum Plain, Erzurum Province

Erzurum. • ***Availability & skills:*** previous pipeline construction experience. Heavy machine operators, heavy vehicle drivers, tree fellers and security personnel are available. • ***Accessibility:*** 18km to Erzurum provincial centre and 8.32km to district centre. A problem free, smooth road linking the settlement with the district centre in a 15-20 minute drive. • ***Information provision:*** 95% of the population is literate. • ***Environmental & cultural sites:*** bone remains of Armenians from the Armenian genocide believed to be in Timar settlement. Historical bridge with '8 niches' under which there is believed to be buried treasure. • ***Infrastructure:*** piped water is available, however supply is irregular. Each house has access to the water supply system. There is no alternative water source. There is electricity and a sewerage system, however, there is no waste disposal system. • ***Services:*** There is no primary school. There is a health care centre and a nurse. • ***Settlement problems:*** unemployment.	***animals*** Trench poses safety hazard for livestock. ***Skills and resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Previous negative experiences*** Possible **opposition** to project and **increased sensitivity** to any negative impacts.	established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints. BOTAS is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be remind**ed of the importance of appropriate behaviour in daily **briefings.**	**involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **Potential positive benefits** to local settlements. Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Environmental Impact Table 18 (Maps 18A and 18B) (KPs 316.7 – 335.7): Karsmanlar Settlement to West of Pasayurdu Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Mesic Coarse-loamy to Coarse-silty Xerochrepts.	Soil related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Other potential impacts will include: • soil erosion; • sediment yield; • reduced soil productivity; • contaminated soils; • waterlogged soils.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.

Environmental Impact Table 18 (Maps 18A and 18B) (KPs 316.7 – 335.7): Karsmanlar Settlement to West of Pasayurdu Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Support equipment on moveable mats. • Avoid freshly irrigated soils.	
Landscape and Visual			
West of Erzurum, the route crosses gently undulating ground, still agricultural but less intensive with poorer soils and, no longer irrigated, more arid. Settlements are fairly frequent, and a number of electricity lines are prominent in the landscape. The route crosses the Pasayurdu Creek, a small river in a pretty, broad, wet marshy valley – the only area with any significant landscape interest along this map section. At KP328 the route crosses a highway, a spur of which continues parallel to the route for about 10km. BVS-017 will be located at KP 322.1 on cultivated land. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 35m in length.	Generally there is a potential for low and short-term construction-related visual impacts, however, visual impacts of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular,	**INDIRECT POSITIVE IMPACT** Landscape is considered resilient to change due to its existing depleted state. Any commensurate enhancements of the degraded NGP alignment will result in a net improvement to the landscape.

Environmental Impact Table 18 (Maps 18A and 18B) (KPs 316.7 – 335.7): Karsmanlar Settlement to West of Pasayurdu Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).	
Groundwater			
The route passes over short distances of unconfined aquifer throughout this section. Water samples taken from Well Site No.9 (Kayapa Settlement Spring), c. 1km east of the route (KPs 317.1 – 325.7), indicate that groundwater quality is Class II.	Potential for moderate and localised impacts to groundwater quality from construction activities.	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including: • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	**MINOR IMPACT** With the application of the specified mitigation measures described, only minor impacts are expected to occur, which will be short-term in nature.
Noise			
Hourly measurements were taken at Karsmanlar and Pasayurdu settlements (Leq values of 50.8 dBA and 59.5 dBA respectively). Values for Karsmanlar settlement are typical of a more rural settlement. Pasayurdu is located c. 127m from the centreline of the Pipeline. Kasmanlar settlement is located c. 364m of the Pipeline and is adjacent to provincial highway crossing.	Noise impacts are expected to occur at Pasayurdu settlement during: • soil stripping; • welding/lowering; • backfilling. Karmanlar settlement will also experience noise impacts	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels;	**MINOR IMPACT** Noise impacts are expected to occur at Pasayurdu during soil stripping and welding/lowering activities. Each individual activity will be short-term in nature, lasting for a few days at a time.

Environmental Impact Table 18 (Maps 18A and 18B) (KPs 316.7 – 335.7): Karsmanlar Settlement to West of Pasayurdu Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	during sheet-piling works at the highway crossing in this area.	• all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, (such as the use of acoustic enclosures for stationary plant and the use of noise barriers), for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	Assuming that the mitigation measures described are applied throughout the construction phase, no significant impacts are expected to occur at Pasayurdu during backfilling or at Kasmanlar during piling.
Archaeology and Cultural Heritage			
The following archaeological sites are located within the 100m Corridor: • Alaybeyi Settlement (3rd Degree Site*) - flat settlement, lying south of the route. No architectural remains are visible due to agricultural activities. Poccik Road (3rd Degree Site*) - flat settlement, lying south of the pipeline. No architectural remains are visible due to agricultural activities.Beypinari-Kahramanlar (2nd Degree Site*) is a flat settlement that will be crossed by the BTC Pipeline route. No architectural remains were observed. * These sites have not yet been registered by the MoC and are provisionally assigned these classifications.	All three sites will potentially be directly impacted and suffer ground disturbance during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of these sites.	Further investigation will be undertaken to route a safe path through Beypinari-Kahramanlar settlement. This will determine the need for detailed surface research and/or rescue excavations at this site. The construction Contractor will adhere to the requirements of the Cultural Heritage Management Plan during construction through this site.	**MODERATE TO MINOR IMPACTS** Residual impacts cannot be determined precisely for Beypinari-Kahramanlar settlement at this stage and will be subject to further investigation prior to construction. However as investigations are expected to find a safe route through this

Environmental Impact Table 18 (Maps 18A and 18B) (KPs 316.7 – 335.7): Karsmanlar Settlement to West of Pasayurdu Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Beypinari-Kahramanlar, Alabeyli settlement and Poccik Road have been proposed for registration by the regional preservation council		Alabeyli and Poccik Road archaeological sites have been avoided through re-routing of the Pipeline. Potential impacts will therefore be avoided at these sites. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	site, the ultimate scale of impact is likely to be minor. **MINOR IMPACTS** Assuming Alabeyli and Poccik Road sites are fenced, impacts will be limited to the temporary disturbance of the setting of the sites and peripheral features.
The foloowing have been proposed for registration by the regional preservation council: (i) Kahramanlar (Karaz) mound; (ii) Karaz mound; (iii) Kahramanlar cemetery			

Social Impact Table 18 (Maps 18C) (KPs 316.7 – 335.7): Karsmanlar Settlement to West of Pasayurdu Settlement, Erzurum Province

Map 18: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There is one block valve station.

Map 18: MAP HIGHLIGHTS

- Area contains Karaz Mound, an archaeological site.
- Unclassified roads link local settlements and National Highway crosses the pipeline.
- Railway passes through area.
- The pipeline crosses two creeks.
- The primary land use in most settlements is agriculture.

IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** eight settlements on this map will have land impacted by the pipeline (L) (Cigdemli, Pasayurdu, Kahramanlar, Ebulhindi (Alaybey), Alaca, Gelinkaya, Karsmaniar and Bascakmak). Two settlements are within 500m of the pipeline (D) (Pasayurdu and Karsmaniar (Kahramanlar). One (Ebulhindi/ Alaybey), is within 2km of the block valve station (B). None are within 5km of a construction camp (C) or pump station (P). Settlements impacted by traffic have not yet been identified. Cigdemli is located downstream of the pipeline.

- ***Surveyed:*** one settlement (Cigdemli) was surveyed in the field (S) and 7 settlements surveyed by telephone (T).
- ***Not surveyed:*** Karsmaniar (650m from the pipeline, surrounds the archaeological site of Karaz Mound), Kuscu (1.23km from pipeline), Kayapa (1.5km from pipeline) and Ebulhindi (1.3km from pipeline).
- ***Not on map:*** Kuscu, Gelinkaya and Bascakmak.
- ***Disclosure Meeting Location:*** Kahramanlar, Pasayurdu

Cigdemli (L) (S)			
• ***Demographics:*** 1,000 inhabitants with 120 households. • ***Safety:*** settlement is situated 2.2km from pipeline. • ***Disputes:*** natural resources, economic, women will liase only with female 'outsiders', not males. • ***Project attitude:*** generally positive. Previous experience with natural gas pipeline. Have expectations of new income-generating activities. 72% of those interviewed have high expectations of direct-employment opportunities and 18% have expectations of land compensation. 54% believe there will be no constraints. 18% think	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Social Impact Table 18 (Maps 18C) (KPs 316.7 – 335.7): Karsmanlar Settlement to West of Pasayurdu Settlement, Erzurum Province

compensation. 54% believe there will be no constraints. 18% think there will be noise and dust impacts, and 18% believe traffic will increase and cause damage to roads. • ***Land ownership & use:*** 60% of the land is privately owned by the local residents. Many title deeds were obtained during natural gas pipeline construction. Grazing occurs and seasonal irrigation activities are undertaken. • ***Settlement livelihood:*** predominantly transportation (there are 60 trucks in the settlement that were used for the natural gas pipeline). Very few households carry out agricultural (grain, vegetables, herbs, sugar beet) and animal husbandry activities. Also some bee keeping (five – six households produce honey), manufacturing, construction, trade, education and local government are the main sources of livelihood. • ***Availability & skills:*** previous pipeline construction and operation experience. Carpenters, heavy machine operators, food service, heavy vehicle operators, drivers, security personnel and welders are available. 91% of those interviewed would accept a temporary job working on the pipeline construction. • ***Accessibility:*** 20km to Erzurum provincial centre and 9km to Ilica district centre. The settlement is accessible all year round. • ***Information provision:*** 100% of the population is literate. • ***Environmental & cultural sites:*** ancient cemetery close to existing pipeline. Also, it is reported that remains from the Byzantine period were excavated during the natural gas pipeline project. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. The settlement is very developed. There is an electricity supply and sewerage system, but no waste disposal system • ***Services:*** there is no primary school, but there is a health centre with three staff including a doctor and a midwife. • ***Settlement problems:*** unemployment, bad roads and dust.	***Skills & resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Conservative settlement*** Construction workers are more likely to offend inhabitants ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings. Any** interaction between construction workers and communities (eg use of local shop) to be carefully monitored **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be	**Potential positive benefits** to local settlements. **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **Low likelihood of significant impacts.** Impacts arising from breeches of rules and procedures. All incidents to be rapidly resolved and used as examples to reinforce procedures. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Environmental Impact Table 19 (Maps 19A and 19B) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils up to KP 340 comprise Mesic Coarse-loamy to Coarse-silty Xerochrepts.	Soil related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Other potential impacts include: • soil erosion; • sediment yield; • reduced soil productivity; • contaminated soils; • waterlogged soils.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.

Environmental Impact Table 19 (Maps 19A and 19B) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Support equipment on moveable mats. • Avoid freshly irrigated soils.	
Soils from KP 340 comprise: • Mesic Fine-loamy to Loamy-skeletal Shallow Typic Xerochrepts on sloping lands. • Possible Xerofluvents on some valley bottom sites near stream and river channels. • Typic Xerorthents on most valley bottoms.	Potential soil productivity and other negative impacts of the NGP accrue to the BTC Pipeline wherever their RoWs lie closely parallel. For the BTC Pipeline other potential impacts include: • soil erosion; • sediment yield; • soil productivity.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Crushed rock. • Permanent erosion control devices. • Sediment interception. • Bio-restoration. • Channel stabilisation - see typical drawings.	
Landscape and Visual			
Generally unremarkable agricultural landscapes, predominantly under cereals. Major highway runs parallel to route until KP 338. From hereon degraded and eroded steppe occurs intermittently with cereals and pastureland on low, rounded, undulating hills. It crosses the Karasu, a wide, fast-flowing river in a broad shingle bed with grass banks, much overgrazed by cattle. Its meanders create visual interest within this exposed landscape. At KP 345 the broad, very wet, marshy valley of the Hoskadem River is crossed providing a further local focus of interest. Industrial and military areas add to the settled character of the area. Irrigated agriculture occurs close to the rivers. BVS-018 and BVS-019 will both be located within cultivated land at KP 344.4 and KP 346.6, respectively. Approximately 350m^2 of permanent landtake required for each site. A new access road will be constructed to BVS-018 of 65m in length and to BVS-019 of c. 45m.	Generally low and short-term construction-related visual impacts, however, visual impacts of the gas pipeline, which was not reinstated, are potentially exacerbated by the BTC Pipeline, wherever their RoWs lie closely or parallel. The marshland either side of the Hoskadem River will be vulnerable to insensitive use of plant and damage will be highly visible. Potential impacts and their	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to	**INDIRECT POSITIVE IMPACT** where the BTC and NGP corridors are successfully reinstated.

Environmental Impact Table 19 (Maps 19A and 19B) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	management during BVS construction will be the same as those during pipeline construction.	ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Near the Hoskadem River, measures to reduce the impact of heavy machinery will include route narrowing, and use of moveable equipment mats to spread vehicle weight and avoid deep rutting. Construction will be undertaken at the driest (July to September) time of the year. Removal/replacement of turfs will be necessary if schedules dictate work during wetter periods (April to June).	
Surface Waters			
The route crosses Karasu River (Kandilli) (KPs 340.5 – 341.8), which supports a major proportion of the aquatic life in the region. River channel is irregular and meandering, with alternating bars and a trapezoidal cross-section. Width of crossing is 35m, with a bank-full width of 29m and a floodplain of between 35 and 175m. Bed consists of sand and gravel and the flow is perennial of a pool and riffle type. Bank-side vegetation comprises shrubs and riparian vegetation is absent. Water quality samples taken 60m upstream of the crossing point indicate that this river is a Class IV river.	Disturbance directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in already poor water quality. Therefore, potential for short-term sedimentation and turbidity.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench.	**MINOR IMPACT** Disturbance will be limited to the immediate working area. Sedimentation of Karasu River (Kandilli) will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 19 (Maps 19A and 19B) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	Potential impacts on downstream ecology and water abstraction for human use.	Assess need for alternative water supply for downstream communities and provide where necessary if sedimentation and turbidity persist for more than 3 days at the community.	
Ecology			
Important Ecological Factors 5 nationally-threatened bird species were recorded in this section - Black Kite (14 at Karasu River crossing (KP 345.6) and 21 at KP 347.2), Bluethroat 3, Barred Warbler 1, and Whinchat 1 (all at Hoskadem River crossing, KP 348.0) and Booted Eagle (1 near KP 352.6). The protection status for these species are given in Table 5.21, Section 5. Only fish species of medium commercial value (see EMMP, Appendix C1) breed in the Karasu River, and include chub (*Leuciscus cephalus*), from April to June, nose carp (*Chondrostoma regium*), from March to May and transcaucasian barb (*Capoeta capoeta angorae*), from May to June.	Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss at the Hoskadem River crossing, if construction is undertaken during the breeding season (ie between April and July inclusive, although the Black Kite and Booted Eagle breed from as early as March). July can remain sensitive for late and second broods. Temporary disturbance to breeding fish species and aquatic plants providing spawning sites for these species during construction across the Karasu River.	Clearance of potential breeding habitat of the Bluethroat and Barred Warbler (ie riverside trees, shrubs and thickets) in advance of the construction of the Karasu and Hoskadem River crossings to be undertaken outside the April to July period. Preconstruction surveys will establish the presence of potential nesting sites for the Booted Eagle and Black Kite within 500m of the pipeline route. If nesting sites are identified, avoidance of construction activity from March to July. Preconstruction survey for evidence of past Black Kite nesting sites. If nesting sites are found within the RoW these will be removed prior to March and after July; where those within 250m of the RoW are observed in April and if nesting is occurring, construction will be avoided until July.	**MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to March, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACTS** at most for all fish species if construction takes place during July to February inclusive. At other times of year (varying by species), impacts will generally be **MINOR** on the basis of the rigid application of water crossing mitigation measures.

Environmental Impact Table 19 (Maps 19A and 19B) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Whinchat (April to July). For construction activity to be permitted during the breeding season of fish species with medium commercial value, the Contractor will be required to submit specific mitigation measures to avoid impacting breeding fish to BOTAŞ for approval. Such measures might include, but not be limited to, the following: preconstruction survey results indicating that spawning grounds are avoided, the provision of fish passages, etc, in addition to the generic mitigation measures that are required at all river crossings.	
Archaeology and Cultural Heritage			
The following has been proposed for registration by the regional preservation council: (i) Abdalcik mound; (ii) Abdalcik Cemetery			

Social Impact Table 19 (Map 19C) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

Map 19: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There are two block valve stations.

Map 19: MAP HIGHLIGHTS

- Unclassified roads link local settlements.
- There are two national highways in the area, one bisects pipeline and one travels parallel to pipeline, c. 2m away from it.
- The pipeline route crosses two rivers.
- The primary land use for most settlements is animal husbandry and agriculture.

MAP 19: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** seven settlements on this map will be directly impacted by the pipeline project (Caykoy, Karabiyik, Abdalcik, Gulludere, Tazegul, Merdiven and Ortabahce). They will all have land intersected by the proposed pipeline (L) and all are within 500m of the pipeline route except Tazegul, Merdiven and Ortabahce (D). One (Karabiyik) is within 2km of the block valve stations (B). None are within 5km of a construction camp (C) or a pump station (P). Settlements impacted by traffic have not yet been identified. There are no settlements downstream of a river/ creek crossing.

- ***Surveyed:*** two settlements (Caykoy and Kandilli) were surveyed in the field (S) and three settlements surveyed by telephone (T).

SITES SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Caykoy (L) (D) (S)			
• ***Demographics:*** 745 inhabitants with 142 households. • ***Safety:*** the centre of the settlement is 1km from pipeline and the nearest house in the settlement is 900m from the pipeline. • ***Health:*** drinking water has been correlated with ill health. • ***Disputes:*** the settlement is divided into 2 groups – those supporting the school principal and those supporting the Muhtar. Also, there are land conflicts between families. Women have no freedom of expression. • ***Project attitude:*** largely positive, however, this settlement will be experiencing expropriation for the 6th time with the BTC project. The State Hydraulic Works, BOTAŞ and other infrastructure related companies have undertaken construction in the settlement, causing damage each time. Past amounts promised for land acquisition were not paid. Different amounts paid for adjacent fields. Local residents	***Conflicts over land boundaries*** Exacerbation of existing conflicts.	**Land boundaries to remain clearly demarcated** at all times. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative	**No significant residual impacts.** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.

Social Impact Table 19 (Map 19C) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

have a preference for the land owner, not the Muhtar to participate in the determination of land prices. 91% of those interviewed believe there will be direct-employment benefits of the project. 72% believe there will be no conflict and 9% believe there will be noise, dust and road traffic impacts. • ***Land ownership & use:*** 90% of the land is privately owned by residents. Land ownership is small-sized. Grazing occurs. Seasonal irrigation is undertaken on some lands. • ***Settlement livelihood:*** main economic activities are agriculture (cereals and sugar beet) and animal husbandry. • ***Availability & skills:*** previous pipeline experience. 82% of those interviewed would accept a temporary job working on the pipeline construction. • ***Accessibility:*** 40km to Erzurum provincial centre and 12km to Askale district centre. The settlement is located on a main road and is accessible all year round. The road is currently being re-asphalted. • ***Information provision:*** 99% of the population is literate. • ***Environmental & cultural sites:*** yes, there are old settlement ruins on the Serceme river on the north of the settlement. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular. Household wells provide an alternative water source. Serious infrastructure problems. There is a sewerage system that does not work and there is no waste disposal system and frequent breakdowns in electricity network. • ***Services:*** there is a primary school, and there is a health care centre. Traditional health techniques are also used. • ***Settlement problems:*** predominantly unemployment, also no profit in produce, low incomes, poor roads and dust.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc. ***Construction hazards: animals*** Trench poses safety hazard for livestock.	sources of water to be provided. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include using appropriate channels of communication and media. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

house in the settlement is 700m from the pipeline. • ***Project attitude:*** according to the Muhtar, the inhabitants are generally positive. • ***Land ownership & use:*** 75% of the land is privately owned by the local residents. Seasonal grazing is undertaken and irrigation occurs. • ***Settlement livelihood:*** agriculture, hunting, construction, education and local government are the main sources of livelihood. • ***Availability & skills:*** previous experience with Iran-Ankara natural gas project. • ***Accessibility:*** 16km to Askale district centre. The settlement is accessible all year. • ***Information provision:*** 80% of the population is literate. The best information provision tools include the newspaper and via family. • ***Environmental & cultural sites:*** nearby hills • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. • ***Settlement problems:*** debt, low income and unemployment.	Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Hunting*** Temporary reduction in game due to disturbance during construction	**held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger to livestock. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Project to **establish level of hunting** in settlements prior to construction.	mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. Significance cannot be established at this time**.**

Social Impact Table 19 (Map 19C) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

		Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc. ***Block Valve Station*** See EIA tables and Overview of the Land Acquisition Process in Appendix C9	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Kandilli (S)			
• ***Demographics:*** 3,000 inhabitants (1,800 military personnel and 1,200 civilians) in 255 households (175 military residences and 80 civilian). Most civilian residents migrate to Erzurum during winter and return to the settlement for the harvest season. • ***Safety:*** the centre of the settlement is 2.5km from pipeline, the nearest house in the settlement is 1.9km from the pipeline.	***Land*** Potential complications in expropriation process. ***Irrigation***	**See Overview of the Land Acquisition Process in Appendix C9.** Contractor will **consult** with	**See Overview of the Land Acquisition Process in Appendix C9.** **If irrigation water is**

Social Impact Table 19 (Map 19C) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

• ***Disputes:*** this is an area where terrorist organisations conduct activities. • ***Project attitude:*** mixed – there is concern about a 3rd pipeline being constructed near their settlement as previous projects led to roads being damaged and there is a history of low expropriation payments. Also, during the natural gas pipeline construction, locals were informed that 'no other expropriation would be made in the future and that the area expropriated for the natural gas pipeline would be used for future works'. • ***Land ownership & use:*** 55% of land is privately owned by the local residents and 20% is communally owned. There is a concentrated land ownership structure. The mobile population tends to own larger areas of land than the permanent population. Grazing occurs. Seasonal irrigation is undertaken, however, irrigation facilities are limited. • ***Settlement livelihood:*** main economic activities are agriculture (grain -predominantly cereals with some lentils, vegetables, herbs, sugar beet), animal husbandry, trade and public services. In addition, bee keeping, fishing, hunting is undertaken. Very mobile population. Half of population are soldiers. Military facilities and the Koy-Tur poultry facilities provide payment for water, thus further contributing to income of Kandilli municipality. • ***Availability & skills:*** previous pipeline and construction experience. 55% of those interviewed would accept a temporary job working on the pipeline construction. • ***Accessibility:*** 38km to Erzurum provincial centre and x km to district centre. A 20km poor quality local access road links the settlement with the main road. The settlement is, however, accessible all year. • ***Information provision:*** 90% of the population is literate. TV is the best local information provision tool. • ***Environmental & cultural site:*** Karabizik Inn. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. There is no sewerage system, however there is a waste disposal system and a settlement dump.	Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility of recruitment*** Decreased access to recruitment process. ***Skills & resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Hunting*** Temporary reduction in game due to disturbance during construction.	authorities to determine maximum acceptable time for disruption. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints. Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects	**disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No residual impact expected.** **Potential positive benefits** to local settlements Significance cannot be established at this time***.***

Social Impact Table 19 (Map 19C) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

• ***Services:*** there is a primary school and a health centre with a midwife and a doctor. • ***Settlement problems:*** unemployment, no profit in produce and low incomes.	***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing.	complaints procedure. **Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Abdalcik (L) (D) (T)			
• ***Demographics:*** 430 inhabitants. • ***Safety:*** settlement is situated 650m from the pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive. • ***Land ownership & use:*** 60% of land is privately owned by the local residents. There is no irrigation and no grazing. • ***Settlement livelihood:*** Agriculture, tourism. • ***Accessibility:*** the settlement is 8.6km from the district centre. • ***Information provision:*** 90% of the population is literate. TV and via family members are the best information provision tools. • ***Infrastructure:*** there is no piped water supply. Instead a local spring provides water. • ***Settlement problems:*** poor access to water, poor roads and unemployment.	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. ***Groundwater***	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **If there is any long term**

Gulludere (L) (D) (T)			
• ***Demographics:*** 600 inhabitants with 85 households. Extensive migration to Izmir occurred in the 1950s. • ***Safety:*** the centre of the settlement is situated 1km from pipeline and the nearest house in the pipeline is 900m from the pipeline. • ***Disputes:*** political instability. • ***Project attitude:*** males are against the pipeline, women have mixed feelings. Any construction will need to be undertaken in a more sensitive manner than that undertaken for the natural gas pipeline; and in undertaking the cadastral survey in the early 1990s. Any tree removed during construction should be replaced. Roads must not be damaged. • ***Land ownership & use:*** all households in the settlement have land. Medium and large-sized farming is dominant. 40% of land is privately owned by the local residents. A renewed cadastral survey is needed to correct the existing situation whereby there are erroneous deeds. (only 7 acres out of 50 acres are cadastred). Seasonal grazing occurs. There is no irrigation. • ***Settlement livelihood:*** main economic activities are agriculture (potatoes, wheat, barley, clover, sugar beet, beans, animal feeds & vegetables) and animal husbandry (directed towards milk production). However, in last three years, there has been a serious decline in	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock.	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage to be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be

Social Impact Table 19 (Map 19C) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

available water for irrigation. In addition, bee keeping (1 household produces honey for own consumption), construction, local government activities are undertaken. • ***Available Skills:*** previous experience with Iran-Ankara natural gas project. • ***Accessibility:*** 70km to Erzurum provincial centre and 8km to Askale district centre. The road to the district centre is poorly constructed and not suitable for transportation, however it is open during the winter, and is accessible all year. A new road is being constructed. • ***Information provision:*** 98% of the population is literate. The best information provision tools include TV, family and the newspaper. • ***Environmental & cultural sites:*** plateau; an old Armenian settlement, however, people are afraid to talk about its history due to allegations surrounding the Armenian genocide. South of settlement is the Tomb of Meram Baba, the remnant of a castle from the Seljukian period. Excavation works are carried out and gold is extracted. • ***Infrastructure:*** piped water is available, however supply is irregular (ie only available for two hours per day). A stored water supply provides an alternative water source. There has been a decline in the amount of underground water originating in the mountains. Due to poor rainfall droughts occur. • ***Services:*** problems with telephone network. Poor water supply. All local residents go to the Askale marketplace on Mondays. There is a primary school with two teachers (four more expected) and 90 students. Parents do not allow girls to attend the 8-year school after 5 years. There is also an un-staffed health centre. • ***Settlement problems:*** poor access to water, political instability and poor irrigation.	***Forest*** Loss of a resource used by settlements. Increased expenditure on other fuel sources. ***Negative experience*** Possible **opposition** to project and **increased sensitivity** to any negative impacts. ***Land*** Potential complications in expropriation process.	for livestock. If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure. BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be remind**ed of the importance of appropriate behaviour in daily **briefings.** **See Overview of the Land Acquisition Process in Appendix C9.**	facilitated by the Projects complaints procedure. **Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement. Level of residual impact will depend on degree to which concerns are resolved prior to construction. **See Overview of the Land Acquisition Process in Appendix C9.**

Social Impact Table 19 (Map 19C) (KPs 335.7 – 359.1): East of Pasa Creek to West of Gulludede Settlement, Erzurum Province

	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
	Conservative settlement Construction workers are more likely to offend inhabitants	**Construction workers will be reminded** of the importance of appropriate behaviour in daily **briefings. Any** interaction between construction workers and communities (eg use of local shop) to be carefully	**Low likelihood of significant impacts.** Potential for impacts arising from breeches of rules and procedures. All incidents will be rapidly resolved and used as examples to reinforce procedures.

Environmental Impact Table 20 (Maps 20A and 20B) (KPs 359.1 – 381.5): Kilickaya Mountains, Erzurum/Erzincan Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Fine-loamy to Loamy-skeletal Shallow Typic Xerochrepts on sloping lands. • Possible Xerofluvents on some valley bottom sites near stream and river channels • Typic Xerorthents on most valley bottoms. • Disturbed parent material. • Mesic Clayey-skeletal to Loamy-skeletal Typic Xerochrepts.	Soil related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Other potential impacts include: • soil erosion; • sediment yield; • soil productivity; • altered drainages.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.

Environmental Impact Table 20 (Maps 20A and 20B) (KPs 359.1 – 381.5): Kilickaya Mountains, Erzurum/Erzincan Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Crushed rock. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	
Landscape and Visual			
As the pipeline route moves west from Askale, it begins to ascend the southern foothills of the Otlukbeli Mountains – a series of rolling hills covered with patchy oak scrub woodlands and degraded steppe used for grazing. Small areas of farming occupy the valley-bottom. Minor streams and rivers are often incised, with channel relief increasing with discharge. The route follows the main highway through a winding valley. The landscapes are unremarkable and have been degraded further by the un-reinstated NGP.	Visual liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures	**INDIRECT POSITIVE IMPACT** Landscape is considered resilient to change due to its existing depleted state. Any commensurate enhancements of the degraded NGP alignment will result in a net improvement to the landscape.

Environmental Impact Table 20 (Maps 20A and 20B) (KPs 359.1 – 381.5): Kilickaya Mountains, Erzurum/Erzincan Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).	
Surface Waters			
The pipeline route crosses Degirmen Creek near KP 375.4, which is also a tributary of Tuz Creek. BVS-020 will be located at KP 376.2, c. 120m from Degirmen Creek. A new access road will be constructed to the BVS site of c. 135m in length.	Existing RoW of the NGP contributes to the sediment load in the channel. Sediment obstructs the river bed. Potential for short-term sedimentation and turbidity of Degirmen Creek and Tuz Creek, during pipeline construction and construction activities associated with BVS-020.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at this watercourse crossing impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).	**INDIRECT POSITIVE IMPACT** where the Degirmen Creek crossing previously disturbed during construction of the NGP is reinstated. **MINOR IMPACTS** Although the water quality classification for Dergirmen Creek is unknown, only minor impacts are expected during construction of both the Pipeline and BVS, as disturbance will be limited to the immediate working area. Sedimentation of Degirmen Creek will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 20 (Maps 20A and 20B) (KPs 359.1 – 381.5): Kilickaya Mountains, Erzurum/Erzincan Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench.	
Ecology			
Important Ecological Factors ESA 14 is identified between KP 359.9 and KP 360.4 for one nationally-threatened plant species, *Tchihatchewia isatidea*. The IUCN status for this species is given in Table 5.20, Section 5. ESA 15 begins at KP 380.4 and continues onto the next map. This ESA is discussed in Environmental Impact Table 21 (see Map 21B). Near KP 359.4, 2 Whinchat (nationally- threatened) were recorded. The protection status for this species is given in Table 5.21, Section 5.	Habitat destruction of plain steppe may result in the loss of individuals from populations of nationally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 14 & 15. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during	**MINOR IMPACT** Short-term disturbance to nationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Environmental Impact Table 20 (Maps 20A and 20B) (KPs 359.1 – 381.5): Kilickaya Mountains, Erzurum/Erzincan Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		until replacement during reinstatement of the RoW. Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Whinchat.	
Noise			
Catalbayir settlement in Askale District, Erzurum Province is located c. 96m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Catalbayir settlement during soil stripping, welding/lowering and backfilling activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be	**MODERATE IMPACT** Due to the proximity of the site to the Pipeline, noise impacts are likely to occur during soil stripping, welding/lowering and backfilling despite noise mitigation measures. However, noise impacts will be short-term occurring for one to two days during each phase of construction. Mobile noise barriers will be utilised to screen plant.

Environmental Impact Table 20 (Maps 20A and 20B) (KPs 359.1 – 381.5): Kilickaya Mountains, Erzurum/Erzincan Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		minimised to the maximum extent possible as part of the PPP (see Appendix C4).	

Social Impact Table 20 (Map 20C) (KPs 359.1 – 381.2): Kilickaya Mountains, Erzurum/Erzincan Border

Map 20: PROJECT INFORMATION			
There are no pump stations or construction camps in the area. There is a block valve station.			
Map 20: MAP HIGHLIGHTS			
• Pipeline runs along the Kilickaya Mountains. • Several creeks cross the pipeline. • The National Highway runs along the path of the pipeline. • Primary land uses are animal husbandry, particularly for milk production, and agriculture (wheat, barley, wild vetch, clover and animal fodder).			
IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** six settlements on this map will be directly impacted by the pipeline project (Yenikoy, Hacihamza, Kukurtlu, Catalbayir, Musatafabey, and Hacibayram). They will all have land intersected by the proposed pipeline (L). Three are within 500m of the pipeline route (Catalbayir, Hacihamza, Kukurtlu) (D). None are within 5km of a construction camp (C) or pump station (P). Two (Musatafabey and Golkdere) are within 2km of a block valve station. Settlements impacted by traffic have not yet been identified. • ***Surveyed:*** 13 settlements were surveyed by telephone (T). • ***Not surveyed:*** Allombasikomi, Musatafabey (1.6km from the pipeline), Gokdere (1.4km from the pipeline), Rizabey Komu (1.1km from the pipeline), Hacibayram (1.75km from the pipeline), Rikanoglu Komu (1.45km from the pipeline), Cinar. • ***Not on map:*** Allombasikomi, Cinar, Agaclar, Gaziler, Gunesken, Kaynak and Senpinar. • ***Disclosure Meeting Location:*** Yenikoy			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**MITIGATION**	**RESIDUAL IMPACTS**
Yenikoy (L) **(T)**			
• ***Demographics:*** 2,000 inhabitants in 180 households with seasonal migration of 10%. • ***Safety:*** settlement is situated 1.25km from pipeline, the nearest house in the settlement is 1km from the pipeline. • ***Settlement conflicts:*** very conservative settlement with no female participation. A number of different political parties supported within the settlement. • ***Project attitude:*** positive, however, promises made during construction of natural gas pipeline were not kept. Fields were destroyed, payment for lands was low, and land inherited but not	***Construction hazards: animals*** Trench poses safety hazard for livestock.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 20 (Map 20C) (KPs 359.1 – 381.2): Kilickaya Mountains, Erzurum/Erzincan Border

destroyed, payment for lands was low, and land inherited but not legally owned caused problems. In addition, lands were not levelled or reinstated, trees were felled, and soil was dumped into creeks, destroying them. • ***Land ownership & use:*** 70% of land is owned communally, although the Muhtar noted that 90% of householders have land. There is some livestock grazing and no irrigation. • ***Settlement livelihood:*** main economic activities are agriculture (wheat, barley, rye & animal feed), animal husbandry and local government are the main sources of livelihood. In addition, some bee keeping (two households produce honey as one of a number of income sources), construction, and trade activities are undertaken. • ***Accessibility:*** 67km to Erzurum provincial centre and 12km to Askale district centre. The settlement is located 3-4km from main road and is accessible all year. • ***Information provision:*** 50% of the population is literate. The best information provision tools include TV and via family members. • ***Environmental & cultural sites:*** castle, caves. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular. A settlement fountain provides an alternative water source. • ***Services:*** there is an elementary school with eight teachers and a health clinic. • ***Settlement problems:*** inadequate access to water, low income and unemployment.	***Land*** Potential complications in expropriation process. ***Accessibility of information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc. ***Conservative*** Construction workers are more likely to offend inhabitants	**See Overview of the Land Acquisition Process in Appendix C9.** ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings. Any** interaction between construction workers and communities (eg use of local shop) to be carefully	**See Overview of the Land Acquisition Process in Appendix C9** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **Low likelihood of significant impacts.** Impacts arising from breeches of rules and procedures. All incidents will be rapidly resolved and used as examples to reinforce procedures.

Social Impact Table 20 (Map 20C) (KPs 359.1 – 381.2): Kilickaya Mountains, Erzurum/Erzincan Border

	Negative experience Possible **opposition** to project and **increased sensitivity** to any negative impacts.	monitored BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings.**	Level of residual impact will depend on degree to which concerns are resolved prior to construction.
Hacihamza (L) (D) (T)	**ADDITIONAL IMPACTS**	**MITIGATION**	**RESIDUAL IMPACTS**
• ***Demographics:*** 56 inhabitants with seasonal migration of 20% • ***Safety:*** the centre of the settlement is 1km from pipeline and the nearest house in the settlement is 800m from the pipeline. . • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive. • ***Land ownership & use:*** all land is privately owned by the local residents. There is no irrigation and no seasonal grazing. • ***Settlement livelihood:*** agriculture, education and local government are the main sources of livelihood. • ***Available Skills:*** previous experience with NGP project. • ***Accessibility:*** 9km to Askale district centre. Poor accessibility from December to February. • ***Information provision:*** 50% of the population is literate. The best information provision tools include TV and the newspaper.	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.**

Social Impact Table 20 (Map 20C) (KPs 359.1 – 381.2): Kilickaya Mountains, Erzurum/Erzincan Border

• ***Infrastructure:*** piped water is supplied to households. Senpinar (T)	ADDITIONAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
• ***Demographics:*** 184 inhabitants. • ***Safety:*** settlement is situated 4.1km from pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive. • ***Land ownership & use:*** 55% of land is privately owned by the local residents. Seasonal irrigation is undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (6 households produce honey, for own consumption), education and local government are the main sources of livelihood. • ***Accessibility:*** 13km to district centre. The settlement is accessible all year. • ***Information provision:*** 90% of the population is literate. The best information provision tools are TV and the telephone. • ***Environmental & cultural sites:*** mausoleum, forest. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. • ***Settlement problems:*** unemployment and low profits.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Forest*** Loss of a resource used by settlements. Increased expenditure on other fuel sources.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.

Environmental Impact Table 21 (Maps 21A and 21B) (KPs 381.5 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Disturbed parent material: • Mesic Clayey-skeletal to Loamy-skeletal Typic Xerochrepts; • Mesic Loamy Xerorthents or Calcixerolls on valley alluvium; • Mesic Xerochrepts associating with Xerorthents and channel gravels on fluvial lands.	Potential soil productivity liabilities of the NGP are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. For the BTC Pipeline other potential impacts include: • soil erosion; • sediment yield; • soil productivity; • altered drainages.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.

Environmental Impact Table 21 (Maps 21A and 21B) (KPs 381.5 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	
Landscape and Visual			
The low-sensitivity landscape is characterised by hilly over-grazed steppe interspersed with arable land and numerous small streams feeding the Euphrates River. West of Tercan the route descends to agricultural land on the broad, flatter river terraces of the Karasu River. Trees are much more in evidence here, often forming field boundaries and clumps along the stream banks. Eroded jagged mountains form a backdrop.	Visual liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management.	**INDIRECT POSITIVE IMPACT** Low sensitivity landscape is considered resilient to change. Any commensurate enhancements of the degraded NGP alignment will result in a net improvement to the landscape.

Environmental Impact Table 21 (Maps 21A and 21B) (KPs 381.5 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).	
Surface Waters			
Route crosses Karamansi Creek at KP 381.1, which is a tributary of Tuz Creek and flows into the reservoir inlet of the existing Tercan Reservoir. Confluence with Tuz Creek is upstream of Yaylacik settlement. Kayaoglu Creek is crossed by the route at KP 389.1. This watercourse flows through Tercan settlement before joining with Tuzla River, which flows into the reservoir inlet of the existing Tercan Reservoir. Route crosses Sor Creek between KPs 389.1 – 391.9, Kislaginsuyu River between KPs 392.6 – 393.3 and Yoncalarin Creek between KPs 393.5 – 396.0. All three watercourses are tributaries of Tuzla River, which then flows into the reservoir inlet of the existing Tercan Reservoir. Kislaginsuyu River and Yoncalarin Creek are crossed by the route and are also tributaries of the Tuzla River, which discharges into the reservoir inlet of the existing Tercan Reservoir.	Existing RoW of the NGP contributes to the sediment load in the channel. Sediment obstructs the river beds. Disturbance, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Therefore, potential for short-term sedimentation and turbidity.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at these watercourse crossings impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity including measures to protect surface waters, such as sediment	**INDIRECT POSITIVE IMPACT** where the watercourse crossings in this section previously disturbed during construction of the gas pipeline are reinstated. **MINOR IMPACTS** Although the water quality classifications for these five watercourses are unknown, only minor impacts expected, as disturbance will be limited to the immediate working area. Sedimentation of all watercourses crossed in this section will only be visible for less than 3 weeks after construction, with no obscuration of the river bed. The impacts of any sediment mobilised during pipeline construction will not be transmitted as far as the Tercan Reservoir.

Environmental Impact Table 21 (Maps 21A and 21B) (KPs 381.5 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		filters/trapping devices, settling ponds and trench de-watering.	
Ecology			
Important Ecological Factors ESA 15 is identified between KP 380.4 and KP 402.0 for twelve globally-threatened plant species (*Gypsophila tuberculosa, Carduus acanthoides spp. sintenisii, Cousinia sintenisii, Tanacetum albipannosum, Hesperis berviscapa, Isatis erzurumica, Stachys subnuda, Astragalus trachytricus, Glaucium cappadocicum, Acantholimon spirizianum var. multiflorum, Thesium stellerioides* and *Verbascum heterodontum*)and four nationally-threatened species (*Helichrysum arenarium var. erzincanicum, Alyssum anatolicum, Tchihatchewia isatidea* and *Acantholimon kotschyi sp. laxispicatum*). A further globally-threatened plant (*Achillea sintenisii*) occurs just outside the 500m Corridor. The IUCN status for these species are given in Table 5.20, Section 5. ESA 15 spans a length of c. 21.6km of the pipeline route and occupies short stretches of Maps 20B and 22B and all of Map 21B. This ESA comprises one of the most sensitive stretches of montane steppe habitat along the route. The Grey Wolf was recorded at KP 388.5. This species is not globally-threatened and has no protection in Turkey, although it is protected under CITES, the Bern Convention and the EU Habitats Directive. At KP 382.1, 4 Pale Rock Sparrow (nationally-threatened) were recorded. The protection status for this species is given in Table 5.21, Section 5.	Habitat destruction of plain steppe may result in the loss of individuals from populations of globally-threatened plants. Potential for minor temporary impacts to wolves as hunting of this species is permitted in Turkey. However, this species is nomadic during spring and summer, which are the optimum months during which pipeline construction is likely to occur. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 15 (entire map). Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. In areas where the presence of	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for wolves with the application of the specified mitigation measures. **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Environmental Impact Table 21 (Maps 21A and 21B) (KPs 381.5 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		wolves has been confirmed, education of workers to be alert and aware of the potential for interactions will include refuse management on sites (particularly where construction camps are located). Furthermore, workers must not wander alone in areas where wolves may be present, especially at night. The hunting of wolves or any other wildlife by the BTC Project Personnel or contractors will be strictly forbidden and rigorously enforced. Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Pale Rock Sparrow.	

Erzincan Socio-Economic Overview

Demographics:
Erzincan is the third smallest of the surveyed provinces in terms of population (280,000), with 14% of this overall population located within the pipeline corridor. Almost 50% of the province population live in rural areas and density levels are relatively low at 34 people per km2. Out-migration is experienced by rural and, to a lesser extent, urban areas. Population levels have increased due to high birth rates and the return of inhabitants during the rebuilding phase following the 1992 earthquake in the province. The largest religious mix along the pipeline is found here with 44% of surveyed households Alevi Muslim, 37% Sunni Muslim and 19% Shafi Muslim.

Land:
According to the State Institute for Statistics (SIS), 37% of agricultural land in the province is irrigated, resulting in diverse agricultural production, including fruits and industrial crops. In the surveyed settlements, land is primarily owned privately by villagers (and is relatively evenly distributed) and secondly is communally owned. Along with Adana and Kahramanmaras, it is one of the highest crop producing provinces along the pipeline.

Livelihoods:
Economically, settlements in the province are similar to other Eastern Anatolian rural settlements and are generally based on agriculture and animal husbandry. Villagers are poor compared to western regions. Residents indicated that State agricultural policies have brought additional problems to the economic situation. Nevertheless, the province was ranked the second most affluent of the surveyed provinces in terms of average household income and assets.

Infrastructure & Services:
There are insufficient infrastructure facilities and services in most settlements. However, the electricity, water and telephone availability was rated as being of moderate to good regularity. Some settlements have primary schools, however in others, children have to travel daily to neighbouring settlements or district centres. Average literacy rates are high (87%) and 72% of respondents have received at least primary or secondary education. Only 2% of respondents have attended university. The settlements have no health centres and generally have to go to the nearest district or town centre for medical treatment.

Key Problems:
Low income is the main problem identified by residents in the settlements. This has been recently exacerbated by increased expenditure on agricultural inputs (e.g. diesel oil, fertilizers). Unemployment is another key problem in these settlements, attributed by participants to a shortage of agricultural opportunities.

Project Attitude:
Villagers are generally negative towards the pipeline, notably due to previous experience (of the East Anatolian Natural Gas Pipeline Project). They perceive that infrastructure will be damaged and no compensation will be given. Villagers are keen to participate in the construction phase and are particularly keen for their younger generations to be involved. Local traders expect the project to increase demand for regional raw materials (e.g. rocks, sand, gravel), manufactured goods (e.g. foodstuffs, cement, bricks) and regional services (e.g. transportation).

Source: Household and Settlement Survey (2001)

Social Impact Table 21 (Map 21C) (KPs 381.2 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

MAP 21: PROJECT INFORMATION

There are no pump stations, construction camps or block valve stations in the area.

MAP 21: MAP HIGHLIGHTS

- Mixed rolling and hilly terrain devoted to grazing.
- Undulating plains support rainfed cereals and irrigated crops.
- The pipeline crosses the Kislaginsuyu River, the Kavaoglu Creek, the Karamanasi Creek and the Yoncalarin Creek.
- Low living standards compared to western regions.
- Rising settlement population levels following an increase in birth rate and return of inhabitants following the 1992 earthquake.
- This province has experienced the NGP.

MAP 21: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** four settlements (Tercan, Aktas, Topalhasan, Begendik) will be directly impacted by the pipeline project. All of these have land intersected by the proposed pipeline (L) and two settlements (Topalhasan, Begendik) are within 500m of the pipeline route (D). No settlements are within 5km of a construction camp (C) or pump station (P), or within 2km of a block valve station (B). Settlements impacted by traffic have not yet been identified. There are three settlements downstream of a river/creek crossing (Topalhasan is downstream on the Kislaginsuyu River, Tercan is downstream of the Kayaoglu Creek and Catakdere is downstream of the Yoncalarin Creek) (R).

- ***Surveyed:*** one settlement (Tercan) was surveyed in the field (S) and four settlements (Aktas, Topalhasan, Karacaviran, Begendik) were surveyed by telephone (T).

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Tercan (L) (district centre) (T/S)			
• ***Demographics:*** 10,898 inhabitants with 1,424 households. There is no reported change in population and there is no seasonal migration. • ***Safety:*** the centre of the settlement is 1.5km from the pipeline. • ***Health:*** there are health problems due to the condition of water including goitre and kidney dysfunctions. • ***Project attitude:*** inhabitants would welcome a construction camp. The general attitude towards the pipeline is positive and supportive. The key concerns relate to issues of compensation, damage restoration, information availability, equal employment opportunity, employee treatment and immediate response to complaints.	***Construction hazards: animals*** Trench poses safety hazard for livestock.	**Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 21 (Map 21C) (KPs 381.2 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

• ***Land ownership & use:*** 60% of land is owned by villagers and 40% is state owned. The landowners have title deeds. There is cultivation of cereals, sugar cane, sugar beet and vegetables. There is also irrigation using permanent channels. There grazing all year round and the main livestock are cattle, sheep and poultry. There is fishing but no hunting. • ***Settlement livelihood:*** agriculture, animal husbandry, bee keeping (ten households, one of many sources of income), fishing (six households, for their consumption) manufacturing, education, trade are the main economic activities. 10% of inhabitants are unemployed (for more than a year), 10% have regular paid jobs and 60% of inhabitants are farmers. • ***Availability & skills:*** there has been previous experience of a pipeline project. The experience has been negative due to the damage that was done to roads and land, but the revenues brought into the district in general seem to have resulted in a more positive attitude. 4 of the 24 possible construction skills including pipe laying, heavy machinery drivers, operators and security personnel are available. 46% of the inhabitants are willing to accept temporary jobs. In addition, there are local resources available including soil and stone quarries. • ***Accessibility:*** the settlement is the district centre, it has good quality asphalt roads that are available all year round. • **Information provision:** Literacy rate is 90%. The main local sources of information are family, friends and neighbours. The main national sources are TV, radio, and newspapers. • ***Environmental & cultural sites:*** religious building and graves. • ***Services:*** phone and mobile services present. Other services include a market, library, bank, police, post office and coffee houses. There are primary and secondary schools with 200 teachers. Health facilities are present, and there are midwives, doctors and a state hospital. • ***Infrastructure:*** there is a regular supply of piped water. There is electricity infrastructure and a sewerage system present but there is no formal waste system.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation. ***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing. ***Skills & Resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Sensitive vegetation used by bees*** Dust may affect yields of	**Information is highlighted to Contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints. **Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure. **Information will be highlighted to Contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints. **Effectiveness of dust suppression** methods to be	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full **Potential positive benefits** to local settlements **No significant impacts** predicted if dust suppression

Social Impact Table 21 (Map 21C) (KPs 381.2 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

no formal waste system. • ***Settlement problems:*** the settlement life standard is deteriorating due to general economic problems. Low income, problems together with agricultural quotas and unemployment are the other key problems.	vegetation (e.g. grey clover) essential for nectar production.	monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	and monitoring measures are fully implemented.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Aktas (L) (T)			
• ***Demographics:*** 180 inhabitants. There has been an increase in the population. 1% of the population migrates seasonally. • ***Safety:*** the settlement centre is 1.8km from the pipeline. • Project attitude: a construction camp would be welcome. There is general awareness of the pipeline and there are no major concerns. • ***Land ownership & use:*** 65% of land is owned by villagers. There is seasonal grazing and temporary irrigation. There is also hunting, bee keeping and fishing. • ***Settlement livelihood:*** agriculture, hunting and trade. Fishing (six households, for their own consumption) and bee keeping (four households, one of many sources of income) also takes place. 90% of inhabitants are family labourers. • ***Availability & skills:*** there is previous experience of the Iran - Ankara natural gas. • ***Accessibility:*** the settlement is not accessible all year round. The settlement is 4km from the district centre. • ***Information provision:*** Literacy rate is 95%. The local sources of information are TV, family, Muhtar and the national sources are TV and the Muhtar. • ***Environmental & cultural sites:*** none • ***Infrastructure:*** there is piped regular water supply. The settlement fountain is an alternative source of water.	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation. ***Hunting*** Temporary reduction in game due to disturbance during construction.	**Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of construction danger to livestock. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Significance cannot be established at this time.**

Social Impact Table 21 (Map 21C) (KPs 381.2 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

• ***Settlement problems:*** inadequate access to water, poor roads and housing problems.		subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport need to be **taken into account** in the recruitment strategy.	**No residual impact expected.**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Topalhasan (L) (D) (T)			
• ***Demographics:*** 30 inhabitants. There has been a recent increase in population. 25% of the population migrates. • ***Safety:*** the settlement centre is 900m from the pipeline. • ***Project attitude:*** a construction camp would be welcome. There is general awareness of the pipeline project, and there are no major	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison**	**Continued attention** to mitigation measures will be critical to prevent injury.

Social Impact Table 21 (Map 21C) (KPs 381.2 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

general awareness of the pipeline project, and there are no major concerns. • ***Land ownership & use:*** 70% of land is owned by villagers. There is seasonal grazing and temporary irrigation. • ***Settlement livelihood:*** agriculture and bee keeping (three households, as one of two sources of income). There are no fisheries. 100% of the inhabitants are farmers. • ***Availability & skills:*** no previous experience. • ***Accessibility:*** the settlement is not accessible and the distance from the settlement to the district centre is 4km. • ***Information provision:*** Literacy rate is 98%. The local sources of information are TV, family, newspapers and the national sources are TV, newspaper and family members. • ***Infrastructure:*** there is a piped although irregular supply of water. A settlement fountain serves as the alternate source of water. • ***Settlement problems:*** housing problems, inadequate water access and infrastructure problems	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Bees*** Disturbance of any stationary hives located within 300m of the route.	**meetings held** prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of construction danger to livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300 meters from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original	**Benefits** from health and safety awareness raising. **Any additional damage to be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of

Social Impact Table 21 (Map 21C) (KPs 381.2 – 401.1): Karamansi Creek to South of Corgu Creek, Erzincan Province

		position for 15-20 days prior to moving back close to their original location.	compensation will be facilitated by the Projects complaints procedure.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. In event of a spill settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
	Accessibility to recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**

		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
Aktas (T)	**ADDITIONAL IMPACTS**	**MITIGATION**	**RESIDUAL IMPACTS**
• ***Demographics:*** 224 inhabitants. • ***Safety:*** settlement is situated 1.75km from pipeline. • Project attitude: according to the Muhtar, inhabitants are generally positive. • ***Land ownership & use:*** 80% of land is privately owned by the villagers. Seasonal grazing occurs. There is no irrigation. • ***Settlement livelihood:*** agriculture, bee keeping (five households produce honey for own consumption) and local government are the main sources of livelihood. • ***Accessibility:*** The settlement is accessible all year round. • ***Information provision:*** 70% of the population is literate. The best information provision tool is TV. • ***Environmental & cultural sites:*** mausoleum, forest. • ***Infrastructure:*** piped water is not available. A local spring is the settlement water source. • ***Settlement problems:*** poor access to water, poor roads and animal farming should be supported by State.	***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc. ***Drinking water*** Potential for disruption or contamination of drinking water during construction ***Special site*** Refer to the Environmental Impact Tables.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low. The need for an **alternative source of water** will be evaluated prior to construction, and if necessary will be provided by the project.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact.**

Environmental Impact Table 22 (Maps 22A and 22B) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Clayey-skeletal to Loamy-skeletal Xerochrepts on slopes; • Mesic Loamy Xerorthents or Calcixerolls on valley alluvium; • Mesic Xerochrepts associating with Xerorthents and channel gravels on fluvial lands.	Potential soil productivity liabilities of the NGP are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Other potential impacts include: • soil erosion; • sediment yield; • soil productivity.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.

Environmental Impact Table 22 (Maps 22A and 22B) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration.	
Landscape and Visual			
The route falls into the flat low sensitivity landscape of the Tercan Plain, which is cultivated intensively and irrigated in places. Trees, particularly poplars, are much in evidence, often planted as windbreaks. The route crosses the Karasu River for the second time. The river here is braided, and the valley is broad comprising numerous shingle ridges and pools, heavily vegetated with willow trees. Further west, the route crosses the Harmantepe Creek, a more scenic, marshy valley with dense willow clumps. The NGP is visible in non-agricultural land. The main highway runs more or less parallel to the route for 6 – 7km. BVS-021 and BVS-022 will both be located within cultivated land at KP 409.2 and KP 411.9, respectively. Approximately 350m^2 of permanent landtake required for each site. A new access road will be constructed to BVS-021 of 40m in length and to BVS-022 of c. 80m.	Marsh either side of the Harmantepe Creek will be vulnerable to damage from insensitive use of heavy machinery. Visual liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline in non-agricultural surroundings. Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil	**INDIRECT POSITIVE IMPACTS** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Loss of trees and bushes at the Harmantepe Creek will leave gaps in the landscape, although this is unlikely to last more than one year after construction.

Environmental Impact Table 22 (Maps 22A and 22B) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Near the Harmantepe Creek, measures to reduce the impact of heavy machinery will include use of moveable equipment mats to spread vehicle weight and avoid deep rutting. Furthermore, construction will be undertaken at the driest time of the year (June to September). Removal / replacement of turfs will be necessary if the construction schedule dictates work during wetter periods (ie April to May).	
Surface Waters			
The route crosses Karasu River (Yesilova), which supports a major proportion of the aquatic life in the region. River channel is anastomose, with mid-channel bars and a parabolic cross-section. Width of crossing is 50m, with a bank-full width of 38m and a total floodplain width of 180m at the crossing point. Bed consists of sand and gravel and the flow is perennial of a pool and riffle type. Long ponded reaches exist between riffles near mid-channel bars. Sand bed is rippled. Bank-side vegetation comprises grass, flora and shrubs with fragmentary riparian vegetation present. Water quality samples taken 1.5km downstream of the crossing point indicate that this river is a Class IV river. Yesilova Quarter is located upstream of the sampling point.	Disturbance, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Potential for short to medium-term sedimentation and turbidity. Potential impacts to downstream bankside communities, where water is abstracted.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities and provide where necessary if sedimentation and	**MINOR IMPACT** Disturbance will be short-term and limited to the immediate working area. Sedimentation of Karasu River (Yesilova) will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 22 (Maps 22A and 22B) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		turbidity persist for more than 3 days at the community.	
Ecology			
Important Ecological Factors ESA 15 continues for c. 900m on this map. ESA 16 is identified between KP 419.8 and KP 420.5 for one globally-threatened plant species – *Cousiana sintenisii* and comprises c. 1km of the pipeline route. The IUCN status for this species is given in Table 5.20, Section 5. The globally-threatened Grey Hamster was recorded near KPs 419.6 – 420.5. The protection status for this species is given in Table 5.21, Section 5. Nationally-threatened birds were observed south of the Karasu River crossing in on a very broad, shingle river plain with islands and marshy areas supporting a rich diversity of riverine and riparian bird life. At least three nationally-threatened species - Great Egret 1, Oystercatcher 2, and White-winged Black Tern 35 were recorded during the bird survey. Also of note was stone-curlew, a species regarded as Vulnerable in a European context, which may have been breeding. One or more of these species is likely to be at or near the BTC Pipeline crossing point upstream. The protection status for these species are given in Table 5.21, Section 5. The European Pond Turtle, a globally-threatened reptile, was recorded at Karasu River. The Tree Frog, a globally-threatened amphibian species, is likely to be found on the banks of this river. The protection status for these species are given in Table 5.21, Section 5. Only fish species of medium commercial value (see EMMP, Appendix C1) breed in the Karasu River, and include chub (*Leuciscus cephalus*), from April to June, nose carp (*Chondrostoma regium*), from March to May and transcaucasian barb (*Capoeta capoeta angorae*), from May to June.	Habitat destruction of plain steppe or areas peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. No seasonal sensitivities were identified for the Grey Hamster. Potential for direct disturbance to nationally-threatened birds at the Karasu River crossing during nesting, feeding or indirectly, through habitat loss, if construction is undertaken during the breeding season (ie between April and July inclusive, although the Black Kite begins breeding as early as March). July can remain sensitive for late and second broods. Temporary local disturbance to globally-threatened reptile species between May and September inclusive. The European Pond Turtle	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 15 and 16. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly. • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Clearance of riverside reedbeds and other dense vegetation in advance of the construction of Karasu River crossing to be undertaken outside the breeding	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACTS** only to globally-threatened reptile and amphibian species, if the construction period avoids the seasonal sensitivity.

Environmental Impact Table 22 (Maps 22A and 22B) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	typically mates in May, with eggs (up to 10 per clutch) laid amongst the roots of waterside vegetation in June. Incubation period is dependent upon variable by temperature, but is generally in the order of 70 days. Hatchlings emerge August – September. Temporary local disturbance during spawning between May and June to the Tree Frog. Temporary disturbance to commercially important fish species and aquatic plants providing breeding sites for these species during construction across the Karasu River.	undertaken outside the breeding season for birds between April to July period. Areas of reeds and dense vegetation will be placed out of bounds for construction workers. In advance of construction works associated with the Karasu River crossing, riverside vegetation will be cleared between beginning of October and end of April, ie outside of the breeding season for the European Pond Turtle. Preconstruction walkover surveys will establish the presence of appropriate spawning locations for the Tree Frog within the RoW of the route; translocation of species to be undertaken in those parts of the route where construction is scheduled to be undertaken between May and June. For construction activity to be permitted during the breeding season of fish species with medium commercial value, the Contractor will be required to submit specific mitigation measures to avoid impacting breeding fish to BOTAŞ for approval. Such measures might	**MINOR IMPACTS** at most for all fish species if construction takes place during July to February inclusive. At other times of year (varying by species), impacts will generally be **MINOR** on the basis of the rigid application of water crossing mitigation measures.

Environmental Impact Table 22 (Maps 22A and 22B) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		include, but not be limited to, the following: preconstruction survey results indicating that spawning grounds are avoided, the provision of fish passages, etc, in addition to the generic mitigation measures that are required at all river crossings.	
Noise			
Gozeler settlement is located c. 250m from the pipeline centreline and is located adjacent to a National highway crossing.	Noise impacts are expected to occur at Gozeler settlement during sheet-piling associated with the highway crossing.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures for the duration of these activities, monitor their effectiveness and	**MODERATE IMPACT** Noise impacts are expected to occur at Gozeler during works associated with the highway crossing. The works will last for three to four weeks. Mobile noise barriers will be used to screen dwellings from construction plant.

Environmental Impact Table 22 (Maps 22A and 22B) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	
Archaeology and Cultural Heritage			
Tasinonu Area Settlement (3rd Degree Site*) is a flat settlement that will be crossed by the route. However, no architectural remains are visible due to prior agricultural activities. * This site has not yet been registered by the MoC and is provisionally assigned this classification. It has been proposed for registration by the regional preservation society	Potential for site to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	The site will be delineated to avoid accidental damage during construction and fenced throughout the construction period. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Assuming the site is fenced, impacts will be limited to the temporary disturbance of the site setting and peripheral features.
(i) Kucuktepe settlement has been proposed for registration by the regional preservation society			

Social Impact Table 22 (Map 22C) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

MAP 22: PROJECT INFORMATION			
There are no pump stations or construction camps in the area. There are two block valve stations.			
MAP 22: MAP HIGHLIGHTS			
• Majority of land use is irrigated agriculture, rain fed agriculture, pasture and meadow. • Undulating plains support rain fed cereals and irrigated crops. • The pipeline crosses a national highway, a railroad, the Karasu River and the Cadirkaya and Kuyubasi Creeks.			
MAP 22: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted**:* six settlements on this map will be directly impacted by the pipeline project. Four settlements (Cadirkaya, Piriz (Caykent), Cayirli Merkez, Harmantepe) have land intersected by the proposed pipeline (L) and no settlements are within 5km of a pump station. Three settlements (Harmantepe, Gozeler and Yesilova) are within 500m of the pipeline route (D), and two (Gozeler and Yesilova) are within 2km of the block valve stations (B). Settlements impacted by traffic have not yet been identified. There are two settlements downstream of a river/ creek (Harmantepe is downstream of the Asku River and Piriz is downstream of the Karasu River). • ***Surveyed**:* three settlements (Cadirkaya, Cayirli, Harmantepe) were surveyed in the field (S) and two settlements (Piriz (Caykent) and Cayirli Merkez) were surveyed by telephone (T). • ***Not surveyed:*** Mirciga (1.6km from the pipeline), (Gozeler and Yesilova 500m from the pipeline).. • ***Not on the map:*** Cayirli Merkez • ***Disclosure Meeting Location:*** Cadirkaya			
SITE SPECIFIC IMPACTS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Cadirkaya (L) (S)			
• ***Demographics**:* 450 inhabitants with 60 households. There has been an increase in population. • ***Safety:*** the settlement centre is 1.7km from the pipeline. • ***Project attitude:*** a construction camp would be welcomed. During a previous pipeline project, fields were damaged, expropriation costs were not paid, water canals and roads were damaged and fields were contaminated. As a result, locals request written commitments regarding land compensation, not just verbal promises. In general the inhabitants are not hostile towards the project. 45% of the inhabitants believe they will benefit from direct employment. • ***Land ownership & use:*** 25% of land is owned by local residents,	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of construction danger for livestock. **See Overview of the Land**	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of the Land**

Social Impact Table 22 (Map 22C) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

25% is communal and 40% is state owned. There is seasonal grazing in Spring, Summer and October. The main livestock are cattle, sheep, poultry. There is cultivation of cereals, sugar cane and sugar beet, and there is seasonal irrigation. There is no fishing, hunting or bee keeping. • ***Settlement livelihood:*** agriculture and animal husbandry. Residents of Gozeler neighbourhood work as seasonal workers for owners of large properties or in metropolitan areas. 100% of inhabitants are family labourers. • ***Availability & skills:*** previous pipeline experience. Only one of 24 possible construction skills is available in the settlement (welding). 82% of inhabitants are willing to accept a temporary job. • ***Accessibility:*** the settlement is accessible from March to December. The distance from the settlement to the district centre is 18km. • ***Information provision:*** The literacy rate is 97%. • ***Infrastructure*****:** there is an irregular supply of piped water. It is the only source. There is electricity infrastructure, but there are no sewerage or waste systems. • ***Services***: phone and mobile services present. There is a primary school but no health facilities are available. • ***Settlement problems***: state support in animal husbandry and the quota being imposed on sugar cane by the government.	expropriation process. ***Irrigation*** Loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Accessibility to recruitment*** Decreased access to recruitment process ***Negative experience*** Possible **opposition** to the Project and **increased sensitivity** to any negative impacts.	**Acquisition Process in Appendix C9** Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these	**Acquisition Process in Appendix C9** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact expected** Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Social Impact Table 22 (Map 22C) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

		communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings.**	
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Caykent (L) **(T)**			
• ***Demographics****:* 1320 inhabitants. There has been an increase in population. 50% of the population migrates. • ***Safety:*** the settlement centre is 2km from the pipeline, and the nearest residence is 1.75km • ***Project attitude:*** a construction camp would be welcome. There is general awareness of the project and there are no major concerns or benefits perceived. • ***Land ownership & use:*** 60% of land is owned by local residents. There is seasonal grazing and temporary irrigation. There is fishing, hunting and bee keeping. • ***Settlement livelihood:*** agriculture, bee keeping (three households, as one of two sources of income), education, fishing (182 households, for their own consumption), hunting, manufacturing, construction, transport, education, trade. 40% of inhabitants have regular paid jobs and 60% are farmers. • ***Availability & skills:*** no previous experience. • ***Accessibility:*** the settlement is accessible year round. the distance from settlement to district centre is 10.3km. • ***Information provision:*** Literacy rate is 95%. The main local and national sources of information are TV, newspapers, Internet and family members.	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing.	**Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of construction danger for livestock. **Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** if there is compensation for any reduction in yields, if and habitat restoration measures are implemented in full.

Social Impact Table 22 (Map 22C) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

• ***Environmental & cultural sites:*** waterfalls. • ***Infrastructure*****:** there is a piped regular supply of water. Stored water is the alternative source. • ***Settlement problems***: inadequate access to water, infrastructure problems and poor irrigation.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Hunting Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	Significance cannot be established at this time.
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. Asking residents or workers to translate as necessary.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Accessibility to recruitment	Winter road closures, seasonal migration and poor	**No residual impact expected**

Social Impact Table 22 (Map 22C) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

	Decreased access to recruitment process ***Special sites*** Refer to Environmental Impact Assessment Tables.	transport will be **taken into account** in the recruitment strategy.	
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Cayirli Merkez (L) **(T)**			
• ***Demographics****:* 4800 inhabitants, with 700 households. There has been an increase in population and 35% of the population migrates. • ***Safety:*** the settlement centre is 3km from the pipeline, the nearest house in the settlement to the pipeline is 2.5km. • ***Project attitude:*** a construction camp would be welcome. There is general awareness of the project and no major concerns or benefits are perceived. • ***Land ownership & use:*** 25% of land is communal and 70% of land is owned by local residents. There is seasonal grazing and temporary irrigation. There is a diverse livestock and cultivation of herbs, vegetables, sugar beet, fruit trees. There is no fishing or bee keeping. • ***Settlement livelihood:*** agriculture, hunting, transport, trade and education. • ***Availability & skills:*** no previous experience, 8 out of 14 construction skills. • ***Accessibility:*** good accessibility as is the district centre. • ***Information provision:*** Literacy rate is 70%. The main sources of information are TV, family members and newspapers. • ***Environmental & cultural sites:*** according to the Muhtar*,* there is a park, waterfalls and a pond. • ***Services:*** there is a primary school midwife, health centre, and doctor. • ***Infrastructure*****:** there is a piped regular supply of water. Stored water	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in expropriation process. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Hunting*** Temporary reduction in game due to disturbance	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of construction danger for livestock. **See Overview of the Land Acquisition Process in Appendix C9** Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Project to **establish level of hunting** in settlements prior	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of the Land Acquisition Process in Appendix C9** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Significance cannot be established at this time**

Social Impact Table 22 (Map 22C) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

is the alternative source. Electricity and waste systems are present. • ***Settlement problems***: unemployment, financial problems, inadequate access to water and poor drinking water quality.	during construction. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Accessibility to recruitment*** Decreased access to recruitment process	to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Harmantepe (L) (D) (S)			
• ***Demographics****:* 1,200 inhabitants with 180 households. There has been an increase in population due to a high birth rate. • ***Safety:*** the settlement centre is 800m from the pipeline and the nearest house is 300m from the pipeline.	***Construction hazard: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison**	**Continued attention** to mitigation measures will be critical to prevent injury.

Social Impact Table 22 (Map 22C) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

• ***Project attitude:*** there is a mixed reaction to the possibility of having a construction camp, near the settlement. The overall attitude is negative due to damage experienced in a previous project. Concerns include damage to irrigation canals and fields, lack of road reinstatement, route changes not compensated for, broken water mains, material left in the fields, expanded construction area and low expropriation payments. There is a concern that determination of land value may not be impartial due to the ethical and political structure of the region. Local residents will be hostile if damages caused during the current project are not restored immediately. 27% of inhabitants believe they will benefit from direct employment and a few of the inhabitants (9%) have concerns of noise, dust and traffic. • ***Land ownership & use:*** 60% of land is owned by local residents and 25% is communal. The landowners have title deeds. Main livestock are cattle. Sheep, poultry are bred for own consumption. Seasonal grazing is important for cattle and sheep. Key crops are grain, herbs, sugar beet. There is seasonal irrigation, with permanent channels. • ***Settlement livelihood:*** arable agriculture and cattle sheep breeding are the main sources of livelihood. Cereals, sugar cane and legumes are grown mainly for subsistence whereas sugar cane is sold in local markets. Cattle and sheep breeding. 70% of inhabitants are family labourers. • ***Availability & skills:*** previous experience, 12 out of 24 construction skills, including welders, drivers, security personnel, food service personnel, woodcutters. 73% are willing to accept temporary jobs. • ***Accessibility:*** roads of low quality asphalt and loose binder dust. Accessible all year. The distance from settlement to district centre is 4km. • ***Information provision:*** Literacy rate is 90%. • ***Services***: mobile and phone services available. Sports facilities, a library and a primary school are available. There is also a health centre, however there are insufficient health personnel. • ***Infrastructure*****:** there is an irregular supply of piped water. There is no alternative source. Electricity supply, sewerage and waste systems are present. Garbage is mixed with fertiliser.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Irrigation*** Loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation. ***Skills and Resources***	**meetings held** prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500m of construction work. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of construction danger for livestock. Contractor will **consult** with authorities to determine maximum acceptable time for disruption **Information is highlighted**	**Benefits** from health and safety awareness raising. **Any additional damage to be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Potential positive benefits**

Social Impact Table 22 (Map 22C) (KPs 401.1 – 420.4): Tercan Plain, Erzincan Province

systems are present. Garbage is mixed with fertiliser. • ***Settlement problems***: general settlement life standard is deteriorating due to general economic conditions, and irrigation is problematic due to the lack of water. The sugar factories have been privatised, the government has decreased the sugar beet quota, and as a result the government buys only a limited amount resulting in a decrease in the prices of sugar beet, impacting upon farmers.	Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Negative experience*** Possible **opposition** to project and **increased sensitivity** to any negative impacts.	**to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints. BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings.**	to local settlements. Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Environmental Impact Table 23 (Maps 23A and 23B) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Clayey-skeletal to Loamy-skeletal Xerochrepts on slopes; • Mesic Loamy Xerorthents or Calcixerolls on valley alluvium; • Mesic Xerochrepts associating with Xerorthents and channel gravels on fluvial lands.	Soil productivity liabilities of the NGP are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. For the BTC Pipeline other potential impacts include: • soil erosion; • sediment yield; • soil productivity.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and gas pipeline corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.

Environmental Impact Table 23 (Maps 23A and 23B) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration.	
Landscape and Visual			
Passing north of Cayirli, the pipeline route keeps to flat, mostly irrigated, agricultural land passing between settlements with their characteristic poplar screens, framed by distant jagged mountain peaks. It weaves along the fairly narrow arid valley of the Aksu River, a broad fast-flowing, shingle-bedded river which it crosses twice, before this opens out into a wide, flat-bottomed, valley with a maze of streams and ditches with bushes and trees, where the route crosses the Aksu for a third time. Landscapes are generally unremarkable although with locally distinct areas along the Aksu River. Numerous settlements lie close to the route. BVS-023 will be located at KP 432.4 over the unconfirmed aquifer. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 30m in length.	Visual liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWS lie adjacent or closely parallel, especially through unfarmed sections. Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil	**INDIRECT POSITIVE IMPACT** Landscape is of generally low sensitivity, although with locally more distinctive pockets. Any commensurate enhancements of the degraded NGP alignment will result in a net improvement to the landscape.

Environmental Impact Table 23 (Maps 23A and 23B) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).	
Surface Waters			
Aksu River is crossed by the route three times – near KP 420.8, near KP 422.5 and between KPs 425 – 430. Width of first crossing [Aksu (Cayirli)] is 30m and the river channel is sinuous. The river has a parabolic cross-section and pool and riffle bars. There is no floodplain. Bed consists of sand and gravel and flow is perennial of a pool and riffle type. Bank-side vegetation comprises shrubs and trees and riparian vegetation has been disturbed. Width of second crossing [Aksu (Balikli)] is 25m and the river channel is sinuous. The river has a parabolic cross-section and pool and riffle bars. There is no floodplain. Bed consists of sand and gravel and flow is perennial of a pool and riffle type. There is no bank-side vegetation and riparian vegetation has been disturbed. Width of third crossing [Aksu (Yesilkaya)] is 25m and the river channel is sinuous. The river has a parabolic cross-section and pool and riffle bars. Floodplain is <250m at the crossing point. Bed consists of cobbles and boulders and flow is perennial of a pool and riffle type. Bank-side vegetation has been artificially cleared and riparian vegetation comprises trees. Water quality samples taken at the three Aksu River crossing points – 110m upstream of the first crossing point, 200m upstream of the second and 660m upstream of the third indicate that this river is a Class IV river. Yesilkaya settlement is located upstream of the third sampling point. Aksu River is a right-bank tributary of Karasu River. Route crosses Doganyuva Creek west of KP 435. Bank-side vegetation has been artificially cleared. The BTC Pipeline crossing lies adjacent and	Disturbance to both watercourses, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Potential for short-term sedimentation and turbidity. The NGP lies adjacent and parallel to both watercourses. Potential impacts on downstream communities, ie Yesilkaya settlement, where water is abstracted for human use.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at these watercourse crossings impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the	**INDIRECT POSITIVE IMPACT** where the Aksu River and Doganyuva Creek crossings previously disturbed during construction of the NGP are reinstated. **MINOR IMPACTS** only expected, as disturbance will be limited to the immediate working area. Sedimentation of Aksu River and Doganyuva Creek crossings will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 23 (Maps 23A and 23B) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
parallel to the existing NGP. The channel is disturbed and has lost the majority of its natural features. Construction of the NGP has caused increased narrowing, which will probably widen with time.		protection of surface waters, including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities. Provide where necessary if sedimentation and turbidity persist for more than 3 days at the community.	
Ecology			
Important Ecological Factors ESAs 17 and 18 occur between KP 424.1 and KP 424.6 and between KP 430.8 and KP 431.3, respectively. These ESAs have been identified for the following globally-threatened plant species, *Cousinia sintenisii* within ESA 17 and *Trigonosciadium intermedium* within ESA 18. The IUCN status for these species are given in Table 5.20, Section 5. Nationally-threatened birds recorded are Oystercatcher (2 at KP 422.2 and 4 at Aksu River crossing); Bluethroat (2 c. 1km north-east of KP 422 and 2 at Buyuk River crossing); Barred Warbler (4 at Aksu River crossing and 3 at Buyuk River crossing (KP 438.1); Honey Buzzard (1 at Aksu River crossing); Booted Eagle (1 at KP 428.4); and Whinchat (1 at KP 428.4 and 1 at Buyuk River (KP 438.1). The protection status for all species identified are given in Table 5.21, Section 5. Aksu River supports chub (*Leuciscus cephalus*), a fish species of medium commercial value breeding in this river between April and June.	Destruction of habitat peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive, although the Booted Eagle begins breeding as early as March). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly ESAs 17 and 18. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). If little or no tree-felling and scrub clearance is feasible at the Aksu River, then impacts will be minor. **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction

Environmental Impact Table 23 (Maps 23A and 23B) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	The Honey Buzzard (*Pernis apivorus*) is a migrant in Turkey and is not thought to breed. This species inhabits woodland areas. Temporary disturbance to commercially important fish species and aquatic plants providing breeding sites for these species during construction across the Aksu River.	sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Clearance of riverside reedbeds and other dense vegetation in advance of the construction of Aksu River crossing to be undertaken outside the April – July period for Oystercatchers. Areas of reeds and dense vegetation will be placed out of bounds for construction workers. Shrubs and dense vegetation along the RoW will be cleared outside the Whinchat's breeding season. Clearance of riverside trees, shrubs and thickets in advance of the construction of the Aksu and Buyuk River crossings to be undertaken outside the April – July period for the Bluethroat and Barred Warbler. Preconstruction survey will establish the presence of potential Booted Eagle nesting sites within 500m of the pipeline route. If nesting sites are identified, avoidance of construction activity	schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April (March for the Booted Eagle), and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACTS** at most for chub if construction takes place outside of the breeding season between April and June inclusive. At other times of year, impacts will generally be **MINOR** on the basis of the rigid application of water crossing mitigation measures.

Environmental Impact Table 23 (Maps 23A and 23B) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		from March to July. Potential nesting sites within the RoW will be removed outside the breeding period. For construction activity to be permitted during the breeding season of fish species with medium commercial value, the Contractor will be required to submit specific mitigation measures to avoid impacting breeding fish to BOTAŞ for approval. Such measures might include, but not be limited to, the following: preconstruction survey results indicating that spawning grounds are avoided, the provision of fish passages, etc, in addition to the generic mitigation measures that are required at all river crossings.	
Noise			
Yaylakent Sub-District Centre in Cayirli District, Erzincan Province, is located c. 26m from the centreline of the pipeline route. Yesilkaya is located c. 400m from the pipeline and the Aksu River crossing.	Noise impacts are expected to occur at Yaylakent Sub-District Centre during all phases of pipeline construction including: • soil stripping; • backfilling; • bending; • trenching • welding/lowering;	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior	**MAJOR IMPACT** The application of mitigation measures will reduce the potential for disturbance at Yaylakent, but due to the proximity of the edge of the settlement to the pipeline route, noise impacts are expected to occur during all phases of construction. Stockpiling of spoil, where

Environmental Impact Table 23 (Maps 23A and 23B) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	• pipe stringing. Noise impacts will also be experienced at Yesilkaya during sheet-piling works associated with the Aksu River crossing.	with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings and where possible, utilising existing screening, including that arising from the stockpiling of materials. The Construction Contractor will develop site-specific noise mitigation measures for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	possible, and mobile noise barriers will be used to screen nearby dwellings from construction works to the maximum extent possible. However, those nearest may still be exposed to temporary construction noise levels that exceed 70dB(A). It is important to emphasise this is a cautious assessment. The construction programme will make provision for a further assessment based on the true numbers of receptors affected and separation distances of receptors from noise sources and take whatever actions are necessary to reduce impacts to an acceptable level. Assuming that the mitigation described is applied to sheet-piling activities at the Asku River crossing, only minor noise impacts are expected to occur at Yesilkaya.
Archaeology and Cultural Heritage			
The following archaeological sites lie within the 100m Corridor. Yesilkaya 2 and Algiz settlement are crossed by the route: • Balikli-1 and Balikli-2 (3rd Degree Sites*) – flat settlements, located to the north of the pipeline route near Balikli Settlement. No architectural remains are visible as a result of agricultural activities. • Algiz Settlement (3rd Degree Site*) – flat settlement, located to the south	Potential for sites to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise	The pipeline has been re-routed to avoid the sites Balikli-1 and Balikli-2. Yesilkaya 2 and Algiz settlement will be delineated to avoid	**MINOR IMPACT** Assuming Yesilkaya 2 and Algiz settlement are fenced, impacts will be limited to the temporary disturbance of the setting of the sites and

Environmental Impact Table 23 (Maps 23A and 23B) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
of the pipeline route. No architectural remains are visible due to agricultural activities. • Yesilkaya 2 (3rd Degree Site*) – flat settlement, located to the south of the pipeline route. No architectural remains are visible due to agricultural activities. * These sites have not yet been registered by the MoC and are provisionally assigned these classifications. Balikli 1, Balikli 2, Algiz settlement and Yesilkaya have been proposed for registration by the regional preservation council The following have been proposed for registration by the regional preservation council: (i) Algiz mound; (ii) Yesilkaya mound; (iii) Yaylakent	from construction activities that will affect the visual/historical setting of these sites.	accidental damage during construction and fenced throughout the construction period. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	peripheral features. **MINOR IMPACTS** at most at Balikli-1 and Balikli-2, which will be limited to the temporary disturbance of the setting of the sites and peripheral features.

Social Impact Table 23 (Maps 23C) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

MAP 23: PROJECT INFORMATION			
There are no pump stations or construction camps in the area. There is a block valve station.			
MAP 23: MAP HIGHLIGHTS			
• Irrigated agricultural land is the predominant land use. • The pipeline crosses the Asku river, the Buyuk river and the Doganyuva creek.			
MAP 23: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** four settlements will be directly impacted by the pipeline project, two settlements (Yaylakent, Baliki) have land intersected by the proposed pipeline (L). Four settlements (Yaylakent, Yesilkaya, Baliki and Pulk) are within 500m of the pipeline route (D). One settlement (Espeverek Verimli) is within 2km of the block valve station (B). No settlements are within 5km of a pump station (P) or construction camp (C). Settlements impacted by traffic have not yet been identified. Two settlements are downstream of a river/ creek (Sebke is at the Asku River pipeline crossing; Yaylakent is downstream of the Buyuk River). • ***Surveyed****:* four settlements (Yaylakent, Yeslikaya, Espeverek (Verimli), Cayirli and Baliki) were surveyed in the field (S). Komga (Doganyuva) was surveyed by telephone (T). • ***Not surveyed:*** Pulk (400m from the pipeline), Komga (Doganyuva) (1.35km from the pipeline). • ***Not on map:*** Pulk • ***Disclosure Meeting Location:*** Yesilkaya			
SITE SPECIFIC IMPACTS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Yaylakent (D) (L) (S)			
• ***Demographics****:* 350 inhabitants with 75 households, increase in population, due to the return of people who emigrated after the 1992 earthquake and in-migration of individuals seeking employment. • ***Safety:*** the settlement centre is 200m from the pipeline, the nearest house in the settlement is 50m. • ***Project attitude:*** a construction camp would not be welcome (minority three out of 11 inhabitants interviewed). Overall attitude is negative since the pipeline will pass through a new settlement area, which is still under development. Previous project damaged land, and compensation towards damages was low. 27% of inhabitants believe they will benefit from direct employment and a few inhabitants (18%) are concerned about noise, dust and traffic.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 23 (Maps 23C) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

• ***Land ownership & use:*** 60% of land is privately owned by local residents, 25% used by local residents, and 15% owned by the state. Land owners have land deeds. There is cattle breeding and seasonal grazing. The key crops are grain, herbs, sugar and beet. There is seasonal irrigation using permanent channels. • ***Settlement livelihood:*** agriculture and bee keeping are important sources of livelihood. Cultivation of cereals, sugar cane and legumes for subsistence. Cattle breeding. 100% of inhabitants are family labourers. • ***Availability & skills:*** no previous experience and limited construction experience only heavy machinery drivers, drivers, and food service personnel are available. 73% of inhabitants are willing to accept a temporary job. • ***Accessibility:*** settlement is accessible throughout the year. Roads are of low quality asphalt and soil. The settlement is 21km from the nearest district centre. • ***Information provision:*** Literacy rate is 100%. • ***Environmental & cultural sites:*** a tree to the south of the settlement was highlighted as an important site. • ***Services***: phone, mobile systems, Gendarmerie, agricultural cooperatives, a market, and coffee houses. There is also a primary school, with three teachers. There is a health centre and a midwife. • ***Infrastructure*****:** there is a regular supply of piped water. Electricity and sewerage systems are present. There is no waste system and some garbage mixed with fertilisers. • ***Settlement problems***: low income and insufficient social services.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Sensitive vegetation used by bees***	construction work. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of construction danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	Any additional damage will be compensated fo***r.*** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 23 (Maps 23C) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

	Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Skills Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials	**Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints.	**Potential positive benefits** to local settlements.
	Negative experience: Possible **opposition** to project and **increased sensitivity** to any negative impacts.	BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these	Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Social Impact Table 23 (Maps 23C) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

	Settlement opposed to construction camp. Nearby construction camp would not be welcomed by some/all settlements.	communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be remind**ed of the importance of appropriate behaviour in daily **briefings.** Additional consultation to be carried out by the project prior to constructing a camp within 5km. Camp will not be located within 5km if against the wishes of the settlement. **Any** interaction between construction workers and communities (eg use of local shop) to be carefully monitored.	**Likelihood of significant impacts dependent on distance of settlement from camp.** Potential impacts arising from breeches of rules and procedures. All incidents to be rapidly resolved and used as examples to reinforce procedures.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Baliki (L) (D) (S)			
• ***Demographics****:* 800 inhabitants with 150 households. There has been an increase in population. • ***Safety:*** the settlement centre is 350m from the pipeline and the nearest residence is 300m from the pipeline. • ***Project attitude:*** a construction camp would ***not*** be welcome (by a minority 2 out of 10 inhabitants interviewed). The overall attitude is negative due to a previous project experience where damage was	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 23 (Maps 23C) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

negative due to a previous project experience where damage was incurred, and the compensation was low. There is a preference for the pipeline to pass through Saritas (Ipekyolu) – Yesilaka which are not fertile lands. They want the pipeline route to change, if not they said they would be very hostile. There is also a preference for Alarko (Tasoren) not to be involved in the BTC project as reportedly did not adopt an impartial attitude in the compensation of damage. They are very concerned about the small river passing through the settlement from which they fish, if the river were to be impacted, it would cause hostility. • ***Land ownership & use:*** 40% of land is used by local residents and 50% of land is communal. There is seasonal grazing and temporary irrigation. • ***Settlement livelihood:*** agriculture, cattle herding and bee keeping. All respondents are family labourers. • ***Availability & skills:*** previous experience. No construction skills are available, although one respondent worked in the installation of a pipeline. 46% of inhabitants are willing to take on temporary jobs. • ***Accessibility:*** roads of low quality asphalt, accessible all year. • ***Information provision:*** Literacy rates are 90%. • ***Services***: there are phone services. There is a primary school and there is also a midwife, health centre. • ***Infrastructure*****:** there is a piped regular supply of water. There are electricity and sewerage systems. There is no waste system and waste is disposed of by recycling and mixing with fertilizers. • ***Settlement problems***: general economic problems, low sugar beet prices and reduction in the sugar beet quota.	Land beyond that compensated for may be affected if mitigation measures not fully implemented ***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. 		communities (eg use of local shop) to be carefully monitored	
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Yeslikaya (L) (S)			
• ***Demographics**:* 500 inhabitants with 75 households. The settlement experienced a decrease in population recently due to emigration. • ***Project attitude:*** a construction camp would **not** be welcome by all inhabitants (11). During the consultation meeting, the general attitude towards the project was negative, due to damages caused by a previous project. Pipeline should pass through Gocyolu not fertile lands. Written commitments required, preference for Alarko (Tasoren) not to be involved in the BTC project as they did not adopt an impartial attitude in the compensation of damages. The key concerns were noise, dust and traffic (18%), the key benefits perceived were direct (18%) and indirect employment (18%). • ***Land ownership & use:*** 98% of land is privately owned by villagers and 2% is communal. Landowners have title deeds. Key crops are grain, sugar beet and cereals. There is temporary irrigation with channels in the same place. Seasonal grazing in Spring, Summer and Autumn. • ***Settlement livelihood:*** agriculture, cultivation of cereals and grain for subsistence. No livestock. 100% of inhabitants are family labourers. • ***Availability & skills:*** previous experience. 0 out of 24 construction skills. 64% of inhabitants are willing to accept temporary jobs. Soil available for construction. • ***Accessibility:*** the roads are low quality asphalt and soil. The settlement is, however, accessible all year. • ***Information provision:*** Literacy rate is 100%. • ***Environmental & cultural sites:*** graves.	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Negative experience*** Possible **opposition** to project and **increased sensitivity** to any negative impacts.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of construction danger for livestock. SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Turnacayiri (P) **(S)**			
• ***Demographics:*** Turnacayirli has a winter population of 10 local residents in two households. There is winter migration to the Cayirli district centre. • ***Safety:*** the settlement is located 5km from the pump station and 2km from the pipeline; the nearest house is 1.9km from the pipeline. • ***Project attitude:*** very positive. • ***Land ownership & use at pump station location:*** state owned land that is not currently used. Surrounding land is privately owned or leased, or communal land that sustains grain and cattle grazing. • ***Local opinion of the pump station:*** generally welcomed. • ***Perceived benefits of the pipeline and pump station:*** employment opportunities on pipeline construction, and potential for improvements in trade and infrastructure. • ***Perceived problems of pipeline and pump station:*** risk of damage to settlement social relations, and risk of damage to land. • ***Settlement livelihood:*** animal husbandry is the main economic activity and agriculture the second activity. • ***Information provision:*** 75-90% of households are literate. • ***Infrastructure:*** electricity and piped water supplied, however there are occasional cuts in the latter and the settlement fountain is then used. There is also a waste disposal system and a primary school but limited health services and poor sanitary conditions.	***Irrigation*** Loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc. ***Accessibility to recruitment*** Decreased access to	***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Communication with settlement ***must take into account settlement characteristics to ensure equal access to information for all residents.*** Winter road closures,	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 23 (Maps 23C) (KPs 420.4 – 440.0): East of Balikli Settlement to Yaylakent Settlement, Erzincan Province

	recruitment process	seasonal migration and poor transport will be taken into account in the recruitment strategy.	No residual impact expected

Environmental Impact Table 24 (Maps 24A and 24B) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Loamy Xerorthents or Calcixerolls on valley alluvium; • Mesic Xerochrepts associating with Xerorthents and channel gravels on fluvial lands; • Mesic Clayey-skeletal to Loamy-skeletal Xerochrepts on slopes below about 2,000m; • Mesic Xerorthents or Xerofluvents near low-lying channels; • Sandy-skeletal Cryochrepts, which may be lithic, on upland slopes; • Cryorthents on upland valleys; • Channel boulders, cobbles, and gravel on fluvial lands. PT3 will be located at KP 444.2. The site has only recently been selected as the preferred location for this pump station. Baseline soil quality information is therefore absent at this stage.	Soil productivity liabilities of the NGP are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Other potential impacts: • soil erosion, particularly at temporary off-site areas associated with the proposed PT3 site; • potential for existing soil contamination at the PT3 site; • sediment yield; • channel alteration.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.

Environmental Impact Table 24 (Maps 24A and 24B) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Crushed rock. • Permanent erosion control devices. Particular attention will be given to erosion control during construction of PT3 due to the location of this site in an area of relatively steep terrain. • An additional survey to record existing baseline soil conditions will be undertaken at the PT3 site to identify any areas of existing soil contamination. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Schedule construction to avoid early spring (April to May).	
Landscape and Visual			
West of KP 435 the route rises along the tributary valleys of the Aksu. The landscape is characterised by largely semi-arid areas with subsistence crops and sheep-grazing. As the route climbs sharply into the Otlukbeli Mountains north of Erzincan the diversity of landform increases with striking broadly-rounded and deeply-dissected hills, almost plateau-like with grassy sub-alpine meadows and montane steppe, used in places for summer grazing. Scattered trees and patches of degraded forest are present. The landscapes here have been badly scarred by the natural gas pipeline, which diverges to the south-west from the BTC route around KP 446. Further west, the land rises further exceeding 2,000m, and the pipeline	High elevation grasslands in the eastern part of the Otlukbeli Mountains are vulnerable to long-term damage because of their poor shallow soils, and harsh climatic conditions will delay reinstatement. Visual liabilities of the NGP, which was not reinstated, are	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures	**INDIRECT POSITIVE IMPACTS** where the landscape scars from the NGP are successfully reinstated. **MODERATE IMPACT** High elevation grasslands may prove difficult to re-instate. Even with care, visual impact can be expected to

Environmental Impact Table 24 (Maps 24A and 24B) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
route encounters a series of north-flowing drainage. Sparse shrubs, small forests, and bare rock characterise the area. The PT3 site occupies a mid-slope position c. 1.3km due south of the settlement of Baskoy and will require a permanent landtake of 18.6ha. In addition, there will be two temporary campsites during the construction period, which will occupy a total of c. 13.4ha. A small road lies c. 250m east of the pump station. The facility will be largely screened to the west by hilly terrain with views only from the tops of hills. Landscape value is considered to be low.	potentially exacerbated by the BTC Pipeline in non-agricultural surroundings. The site at PT3 is predicted to be visible for up to c. 4km predominantly to the north and south. The high sensitivity viewers that will experience the potential impacts during construction are residents in the settlement of Baskoy, particularly those on the southern edge of the settlement whose view will not be screened by other houses. The southern edge of Baskoy is c. 1.25km from PT3.	prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).Carefully remove, store, nurture, and replace turfs. PT3 has been located within the rural environment to minimise its impact on residential properties. In addition, the locally varied terrain around PT3 will offer some natural screening potential during construction. Mitigation measures in Section 6.3, including: • minimising the removal of mature trees prior to construction, will also be applied; • full reinstatement of all areas of non-permanent landtake, such as temporary construction camps.	remain for several years. **MODERATE IMPACTS** Moderate visual impacts on residential properties with medium distance views of PT3. However, this impact will occur for a limited period during construction (see Section 7.2.2 for an assessment of operational landscape and visual impacts).

Environmental Impact Table 24 (Maps 24A and 24B) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Surface Geology and Geohazards			
Landslides Route crosses the toe area of the active landslide area of Gulluce between KPs 455.1 – 455.7. This is a major deep-seated earth flow and debris slide complex, c. 400m wide that occupies the valley floor and extends upslope for c. 1.5km.	Pipeline construction adds to the risk of a landslide along this section of the route. Potential physical damage to pipeline, landscape and watercourses.	Permanent erosion control devices. The pipeline will be buried to extra depth, sufficient to bury it into stable ground, for a 200m length under the toe of the landslide to avoid any interactions during operation. See *Detailed Engineering Pipeline Risk Assessment*.	**MINOR IMPACT** Landslides pose a potential threat to the Pipeline. Construction and reinstatement activities will be undertaken in such a way so as not to add to the risk of a landslide.
Surface Waters			
The pipeline route crosses Cilhoroz Creek near KP 450.0. Turnacayiri settlement is 2.2km downstream of the crossing point. The proposed DSI Cayirli Dam is proposed to be located downstream of Cilhoroz Creek. This project will provide irrigation water to agricultural fields in the vicinity, over an area of approximately 13,000ha.	Disturbance to Cilhoroz Creek, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Potential for long-term sedimentation and turbidity. The NGP lies adjacent and parallel to the creek. Potential for indirect disturbance at Cayirli Dam, resulting in a reduction in water quality.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at this watercourse	**INDIRECT POSITIVE IMPACT** where the Cilhoroz Creek crossing previously disturbed during construction of the NGP is reinstated. **MINOR IMPACTS** Although the water quality classification for Cilhoroz Creek is unknown, only minor impacts expected, as disturbance will be limited to the immediate working area. Sedimentation of Cilhoroz Creek will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 24 (Maps 24A and 24B) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		crossing impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity at the Cilhoroz Creek crossing point, including measures to protect surface waters flowing into the reservoir, such as sediment filters/trapping devices, settling ponds and trench de-watering.	
Ecology			
Important Ecological Factors ESA 19 is identified between KP 445.5 and KP 447.9 for five globally-threatened plant species (*Onosma liparioides, Campanula hedgei, Isatis cappadocica sp. alyssifolia, Astragalus elbistanicus* and *Haplophyllum cappadocicum*). ESA 20 is identified between KP 451.7 and 458.4 for seven globally-threatened plant species (*Onosma liparioides, Helichrysum arenarium spp. Erzincanicum, Jurinea brevicaulis, Alyssum lepidoto-stellatum, Galium hypoxylon, Galium papilliferum* and *Thesium aureum*) and one nationally-threatened species (*Acer divergens var. trilobium*). The IUCN status for these species are given in Table 5.20, Section 5. At KP 448.1, Whinchat (nationally-threatened) were recorded. The protection status for this species is given in Table 5.21, Section 5. The PT3 site will be located at KP 444.1 on the edge of ESA 19. Ecological surveys undertaken in mid-2002, indicated that the site of PT3 is	Habitat destruction of montane steppe may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 19 and 20. Since *Onosma liparioides* occurs within both ESAs 19 and 20, diligence will be exercised in searching for it between these two areas. Similarly, other globally-threatened plants were found along the previous route corridor – a search for these species along the current route will also be made prior to construction. The feasibility of translocating species will be	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction

Environmental Impact Table 24 (Maps 24A and 24B) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
ecologically degraded due to high human activity in the area.	broods.	assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Whinchat. At the PT3 site, preconstruction surveys will determine the need to apply the following measures: • extra care will be taken at this site to ensure the area affected by construction activities is minimised where practicable and the location of laydown and staging areas will be determined	schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Environmental Impact Table 24 (Maps 24A and 24B) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		in consultation with ecological advisors to avoid sensitive species as far as practicable. • any particularly sensitive areas near the PT3 site, as determined by botanical specialists, will be fenced or clearly demarcated and will be off-limits to all construction personnel.	
Noise			
Cilhoroz settlement in Cayirli District, Erzincan Province is located c. 141m from the centreline of the Pipeline, and is near to a crossing of the NGP. Baskoy is located c. 418m from the centreline, and is also located near to a crossing of the NGP.	Short-term noise impacts are expected to occur at Cilhoroz settlement during soil stripping, excavation works and welding/lowering. In addition, sheet piling works associated with the NGP crossings will give rise to noise impacts at Cilhoroz and Baskoy.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for	**MODERATE IMPACT** Due to the proximity of the Cilhoroz to the Pipeline, noise impacts are expected to occur during soil stripping, welding/lowering and piling activities. Soil stripping and welding/lowering activities will be short-term in nature. However, works at the NGP will take three to four weeks to complete. Application of the mitigation measures described will minimise the potential for disturbance at Baskoy during piling and at Cilhoroz during excavation works.

Environmental Impact Table 24 (Maps 24A and 24B) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	
Archaeology and Cultural Heritage			
The site at PT3 has only recently been selected as the preferred location for PT3. The archaeological potential in the vicinity of the PT3 site has not been assessed. Baseline archaeological investigations will be undertaken of surface features at the site and surrounding areas prior to construction to confirm the presence, or potential presence, of archaeological features.	To be determined once an archaeological investigation of the site has been undertaken prior to construction.	To be determined as appropriate.	To be determined as appropriate.

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

MAP 24: PROJECT INFORMATION			
There is a pump station in this area (PT3). It requires 18.58ha of non-cultivated land, located on mountainous, largely barren terrain. Due to the terrain it will be constructed on nine levels. Adjacent to the pump station is its temporary construction camp (13.44ha). This camp is split into two sections on either side of a ridge. There are no block valve stations in the area.			
MAP 24: MAP HIGHLIGHTS			
• The majority of the route passes through pasture land. • The route crosses two irrigated agricultural areas. • Undulating plains support rainfed cereals and irrigated crops. • The pipeline crosses the Kozoglu creek and the Cilhoroz creek. • The Cayirli dam intersects with the pipeline corridor to the south.			
MAP 24: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted****:* six settlements will be directly impacted by the pipeline project, two of these (Baskoy and Cilhoroz) have land intersected by the proposed pipeline (L) and three settlements (Baskoy, Peyler (Esendoruk), Orensehir) are within 5km of the pump station (P). Three of the settlements are within 500m of the pipeline route (Baskoy, Verimli, Cilhoroz) (D). No settlements are within 2km of a block valve station (B). Settlements impacted by traffic have not yet been identified. • ***Surveyed****:* five settlements (Baskoy, Orensehir, Esendoruk, Yaylacik and Ulucak) were surveyed in the field (S). • ***Not surveyed:*** Cilhoroz (300m from the pipeline), Deliktas (950m from the pipeline). • ***Not on the map:*** Orensehir, Yaylacik and Ulucak.			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Baskoy (L) (P) (D) (S)			
• ***Demographics:*** summer population of 200 inhabitants with 50 households and a winter population of 50 people in 20 households. There has been an increase in population, following the 1992 earthquake due to people returning from Istanbul. Winter migration occurs to the Cayirli district centre. • ***Safety:*** Baskoy is located 1km from the pump station (visible). The settlement centre is 750m from the pipeline and the nearest house is 500m from the pipeline. • ***Health:*** contagious diseases occur occasionally. • ***Project attitude:*** a construction camp would be welcome. General opinion is positive, provided no damage occurs. In a previous project	**PUMP STATION IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction of the pump station. See Sections 6 and 7 and the Overview of the Land Acquisition Process in Appendix C9.		

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

opinion is positive, provided no damage occurs. In a previous project local residents reported that damage was caused to most of the land, and the spring water. No payments were made in return for pastures taken away from the settlements. • ***Land ownership at pump station:*** the proposed site will occupy 18.58ha of state owned land. • ***Land ownership at pump station construction campsite:*** the campsite is immediately adjacent to the pump station. It will be 13.44ha in size, all of which is registered land, privately owned by Baskoy local residents. • ***Land ownership & use:*** surrounding land is privately owned or leased, or communal land that sustains grain and cattle grazing (40% of land is privately owned by local residents, 45% is used by local residents but not owned, and 5% of land is state owned). Landowners have title deeds. State owned land that is not currently used. The key crops are grain, sugar and beet. There is seasonal irrigation using permanent channels. There is sheep and cattle breeding with seasonal grazing in Spring, Summer, October and November. • ***Local opinion of the pump station:*** generally welcomed. • ***Perceived benefits of the pipeline and pump station:*** employment opportunities on pipeline construction and potential for improvements in trade and infrastructure. • ***Perceived problems of pipeline and pump station:*** risk of damage to settlement social relations, and risk of damage to land. • ***Settlement livelihood:*** animal husbandry is the main economic activity and agriculture the second activity. Cultivation of cereals, and sugar cane is mainly for subsistence. Sheep and cattle breeding is becoming unprofitable. 50% of inhabitants are family labourers. • ***Availability & skills:*** previous pipeline experience. Two construction skills out of 24 including drivers and repairmen. 92% are willing to accept temporary jobs. • ***Environmental & cultural sites:*** graves • ***Accessibility:*** Baskoy is located next to the pump station road (the old Erzincan Highway). The roads are made from soil and are in a	***Traffic*** The road that would be used to access the site would pass through Baskoy. Potential impacts due to traffic. ***Land*** Permanent land expropriation of 18.58ha will occur. ***Livelihoods*** Decreased land resources may result in decreased livelihood opportunities. ***Pump Station Construction hazards: humans*** Working areas pose safety hazards to residents, particularly small children.	Measures to assure the safety of and reduce the nuisance to the inhabitants to be incorporated. (refer to Section 6) Evaluate the possibility of assigning unused state owned pastureland. **See Overview of the Land Acquisition Process in Appendix C9.** **See Overview of the Land Acquisition Process in Appendix C9.** **Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work.	**No residual impacts** Potential loss of land. **See Overview of the Land Acquisition Process in Appendix C9.** **See Overview of the Land Acquisition Process in Appendix C9.** **Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

old Erzincan Highway). The roads are made from soil and are in a very bad condition but are usable in the winter. The district centre is 27km from the settlement. • ***Information provision:*** 75-90% of households are literate. • ***Infrastructure:*** electricity and piped water supplied, however there are occasional cuts in the latter and the settlement fountain is then used. There is also a waste disposal system, Garbage is mixed with fertilisers. • ***Services:*** there is a primary school but limited health services and poor sanitary conditions. • ***Settlement problems***: unemployment, there is a danger from flooding, and the people need a new settlement location. Deteriorating life standard due to general economic conditions and animal breeding becoming unprofitable and a lack of services including sewerage.	***Pump Station Construction hazards: animals*** Site poses safety hazard for livestock. **PUMP STATION CONSTRUCTION CAMP IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction workers ***Land*** Temporary land expropriation (13.44ha) will occur.	***Consider erecting*** *stock proof fencing* ***in areas of danger for livestock.*** **Monthly community liaison** meetings will be held**.** **Preferential employment opportunities.** **Project to liase** with local health authorities. BTC Company to look at opportunities to cooperate in providing **health awareness training.** Evaluate the possibility of assigning unused state owned pasture land.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **Low likelihood of significant impacts.** Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures. **Low likelihood of significant health impacts.** **Benefits** from raising health awareness of the workforce (many of whom will be local). Further positive benefits dependent on the scale of community investment activities. **See Overview of the Land Acquisition Process in Appendix C9.**

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

	PIPELINE IMPACTS:		
	Construction hazards: animals Trench poses safety hazard for livestock	**Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.
	Construction hazards: humans Working areas pose safety hazard to residents, particularly small children	**Road safety training in** schools and for wider community prior to construction. **Community liaison meetings** prior to construction to include safety.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from awareness raising.
	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** during and immediately following construction to identify any land that has been affected. Consider erecting protective barrier fencing.	**Additional damage to be compensated for.**
	Land Potential complications in expropriation process.	**See Overview of the Land Acquisition Process in Appendix C9.**	**See Overview of the Land Acquisition Process in Appendix C9.**
	Irrigation Potential loss of flow from planned/ accidental	Contractor will **consult** with authorities to determine	**If irrigation water is disrupted** longer than time

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

	disruption. Contaminations of flow from spills or increase in sedimentation.	maximum acceptable time for disruption.	considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc.	Communication with settlement must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Accessibility to recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
	Health Potential health impacts on construction workers.	**Information is highlighted to contractor** so that they can ensure that their workers are protected.	**No residual impact.**
		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.

Payler (Esendoruk) (P) (S)			
• ***Demographics**:* there is a summer population of 100 people in 20 households and a winter population of 28 people in seven households. Winter migration to Cayirli district centre occurs. The population is slowing increasing. • ***Safety:*** the settlement centre is 2.1km from the pipeline and 2km from the pump station. • ***Disputes:*** there is a dispute in the settlement over use of pasture land. • ***Project attitude:*** very positive, although the local residents are concerned that the negative impacts experienced during construction of the natural gas project may be repeated. • ***Land ownership & use at pump station location:*** the proposed site will occupy 18.58ha of state owned land. • ***Local opinion of the pump station:*** inhabitants generally welcome a pump station. • ***Perceived benefits of the pipeline and pump station:*** employment opportunities on pipeline construction and in the construction camps; indirect employment opportunities ie provision of goods & services; and potential for improvements in trade and infrastructure. • ***Perceived problems of pipeline and pump station:*** risk of damage to settlement social relations, risk of damage to land, and potential for increased traffic in and nearby the settlement. • ***Settlement livelihood:*** animal husbandry is the main economic activity and agriculture (grain & herbs) the second activity. 1% of the population have a regular paid job. • ***Accessibility:*** the settlement is 29km from the district centre. It is inaccessible during winter (December, January, February). • ***Information provision:*** 75% of the population is literate. • ***Infrastructure:*** no piped water, no regular supply, local spring alternative source.	**PUMP STATION IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction of the pump station. See Sections 6 and 7 and the Overview of the Land Acquisition Process in Appendix C9. **PUMP STATION CONSTRUCTION CAMP IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction workers	**Monthly community liaison** meetings will be held**.** **Preferential employment opportunities.** **Project to liase** with local health authorities. BTC Company to look at opportunities to cooperate in providing **health awareness training.**	**Low likelihood of significant impacts.** Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures. **Low likelihood of significant health impacts.** **Benefits** from raising health awareness of the workforce (many of whom will be local). Further positive benefits dependent on the scale of

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

• ***Services:*** no electricity supply or telephone service in the settlement, although there is a basic sewerage and a waste disposal system. No primary school, poor health services and poor sanitary conditions. • ***Settlement problems***: transportation and lack of electricity	**PIPELINE IMPACTS:** ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Accessibility to recruitment*** Decreased access to recruitment process ***Drinking water*** Potential for disruption or contamination of drinking water during construction	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. Asking residents or workers to translate as necessary and emphasising oral communication where literacy is low. Winter road closures, seasonal migration and poor transport need to be **taken into account** in the recruitment strategy. The need for an **alternative source of water** will be evaluated prior to construction, and if necessary will be provided by the Project.	community investment activities. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact expected** **No residual impact.**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Yaylacik (S)			
• ***Demographics****:* 300 inhabitants with 70 households. No change in population. • ***Safety:*** the settlement centre is 3.1km from the pipeline.	No additional impacts identified.		

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

• ***Project attitude:*** a construction camp would be welcomed and there is no hostility towards the project although the general attitude is partially positive since the existing pipeline passes through pastures. There are no major concerns, except traffic impacts (18%), and 36% felt that they would benefit from direct employment. • ***Land ownership & use:*** 60% of land is owned privately by local residents, 25% is communal and 15% is by share cropping. Landowners have title deeds. A diverse range of livestock is kept, with seasonal grazing in May and November. The inhabitants mentioned that the land was unproductive. Key crops are grain, herbs. There is no temporary irrigation. • ***Settlement livelihood:*** agriculture is the main source. Cultivation of cereals and legumes for subsistence. Beekeeping tales place. 100% of inhabitants are family labourers. • ***Availability & skills:*** previous experience. Only a few skills are available (two of 24 possible construction skills) including laying pipes and driving. 64% of inhabitants are willing to accept temporary jobs. • ***Accessibility:*** settlement roads of poor quality asphalt and loose binder dust, but can be used in winter. The distance from settlement to district centre is 10km. • ***Information provision:*** Literacy rates are 100%. • ***Environmental & cultural sites:*** none • ***Services***: there are schools and there are no health facilities. • ***Infrastructure*****:** there is a piped, regular supply of water. Electricity and sewerage systems are present. No waste system and waste is disposed of by burning, recycling, mixed with fertilisers. • ***Settlement problems***: lack of water, water mains are insufficient, roads need to be asphalted, a bridge is needed over the stream flowing through the settlement, and life standards are deteriorating due to the national economic downturn.			

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Ulucak (S)			
• ***Demographics**:* 150 inhabitants with 28 households. No change in population. Migration of families to Istanbul during winter months. • ***Safety:*** 1.9km from the pipeline • ***Project attitude:*** while a construction camp would be welcomed, attitude to the project is **very negative** due to previous damage to land and water ducts during construction of the natural gas pipeline. Damaged irrigation canals were not reinstated by subcontractor firm Serefoglu during the natural gas pipeline construction. Trees cut down and not compensated for, water resources damaged and not compensated, land not reinstated, expropriation costs were low and promises were not kept by BOTAŞ during the construction of the pipeline. *"if necessary I will lie down in front of the bulldozers"*, they do not want their lands acquired and demand a monthly salary for use of their lands. 18% of inhabitants believe they will benefit from direct employment. • ***Land ownership & use:*** 100% of land is privately owned by local residents and landowners have title deeds. Cattle breeding takes place with seasonal grazing in Spring, Summer and Autumn. There is seasonal irrigation with permanent channels. • ***Settlement livelihood:*** agriculture, cultivation of cereals and grain and cattle breeding. Cultivation mainly for subsistence. Beekeeping takes place. 14% of inhabitants have regular jobs (paid), 22% are family labourers. • ***Availability & skills:*** no previous experience. No construction skills are present. 36% of inhabitants are willing to accept temporary jobs. Stones are available for construction. • ***Accessibility:*** the settlement is accessible throughout the year. There is an auxiliary road connecting the settlement to main road, which is constructed out of low quality asphalt, and the roads within the settlement are constructed out of soil, and available in the winter. The distance from settlement to district centre of Refahiye is 6.3km	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Accessibility to recruitment*** Decreased access to recruitment process ***Negative experience*** **Possible opposition** to project and **increased sensitivity** to any negative impacts.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Communication with settlement must take into account settlement characteristics to ensure equal access to information for all residents. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact expected** Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Social Impact Table 24 (Map 24C) (KPs 440.0 – 463.1): Otlukbeli Mountains, Erzincan Province

6.3km. • ***Information provision:*** Literacy rate is 100%. • ***Environmental & cultural sites:*** cultural site, grave of a notable person within the community. • ***Services***: there is no school, the nearest one is 9km away. There are no health facilities. • ***Infrastructure*****:** there is a piped, regular supply of water. Electricity, sewerage systems are present, the latter is lacking in some places. No waste system, and the source of waste disposal is recycling and mixing garbage with fertilisers. • ***Settlement problems***: income, relatively poor settlement, due to increasing costs for cultivation, and the potential land cannot be evaluated to a full extent.		any negative impacts are rapidly identified. **Construction workers to be remind**ed of the importance of appropriate behaviour in daily **briefings.**	

Environmental Impact Table 25 (Maps 25A and 25B) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Clayey-skeletal to Loamy-skeletal Xerochrepts on slopes below about 2,000m. • Mesic Xerorthents or Xerofluvents near low-lying channels. • Sandy-skeletal Cryochrepts, which may be lithic, on upland slopes, along the spine of ridges. • Cryorthents on upland valley bottoms and lower slopes. • Channel boulders, cobbles, and gravel on fluvial lands.	Potential soil productivity liabilities of the NGP are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel Other potential impacts include: • soil erosion; • sediment yield; • saturated soils; • channel alteration.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and gas pipeline corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.

Environmental Impact Table 25 (Maps 25A and 25B) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Crushed rock. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Schedule construction to avoid early spring (April to May).	
Landscape and Visual			
The route continues to ascend across the summits of the narrow, prominent ridges that dominate the landscape. High relief forces the Pipeline to rise and fall through numerous canyons. The route crosses through c. 1-2km of sections of Guzyurdu Forest. Small settlements occupy valley bottoms where these widen out. Shrubs dominate slope vegetation, with forests occupying only scattered slopes; grassland covers U-shaped and gently sloping valley bottoms, with coarser, riparian vegetation along stream banks. Valley bottoms near settlements are farmed. Bare ground on steep slopes is common. Landscape sensitivity is moderate.	High elevation grasslands in the eastern part of the Otlukbeli Mountains are vulnerable to long-term damage because of their poor shallow soils, and harsh climatic conditions will delay reinstatement. However diverse landform offers opportunities to screen the route.	• Optimise landform screening effects. • Carefully remove, store, nurture, and replace turfs.	**MODERATE IMPACT** High elevation grasslands may prove difficult to re-instate. Even with care, visual impact can be expected to remain for several years.
Ecology			
Important Ecological Factors ESA 21is identified between KP 468.9 and KP 472.5 for five globally-threatened plant species (*Hypericum scabroides, Astragalus crinitus, Alchemilla ciminensis, Alchemilla erzincanensis* and *Bupleurum eginense*) and one nationally-threatened species (*Acer divergens var. trilobium*). ESA 22 is identified between KP 476.5 and KP 481.8 for three globally-threatened species (*Onosma sintenisii, Paracaryum lithospermifolium var.*	Habitat destruction of montane steppe and mixed forest may result in the loss of individuals from populations of globally-threatened plants. The pipeline route skirts the	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 21 & 22. The feasibility of translocating species will be assessed prior to construction. Where only a few	**MODERATE IMPACT** Short-term disturbance to internationally important flora and possibly fauna. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the

Environmental Impact Table 25 (Maps 25A and 25B) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
erectum and *Veronica montbretii*) and one nationally-threatened species (*Campanula ptarmicifolia var. ptarmicifolia*). The IUCN status for these species are given in Table 5.20, Section 5. Guzyurdu Forest is possibly the most important area for large mammals along the route, although the forest has no protection status, and includes notably Wild Goat, Chamois (both globally-threatened), Brown Bear, Grey Wolf and Roe Deer. The smaller mammals that attract attention within this forest are Eurasian Otter, Forest Dormouse (both globally-threatened), Beech Marten, European Pine Marten and Eurasian Badger. The protection status for these species are given in Table 5.21, Section 5. BVS-024 will be located at KP 463.4 within montane steppe habitat. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 1,088m in length. BVS-025 will be located at KP 468.9 within ESA 21 and BVS-026 at KP 480.1 in ESA 22, both sites within montane steppe habitat. Approximately 350m^2 of permanent landtake required for each BVS. New access roads will be constructed to BVS-025 and BVS-026 of c. 35m in length.	edge of low grade forest and therefore only minor temporary disturbances are expected to globally-threatened mammals during seasonal sensitivities (see EMMP, Appendix C1): • hibernation and peak spring feeding periods for brown bears between November to April and March to June, respectively; • breeding season for wild goats between October and December and during birthing between March and April; • breeding season for Turkish Chamois is in the autumn, with young are born in March and April; • breeding season for the Eurasian Otter is year round in Turkey, with a tendency towards the spring period in cooler regions; • breeding season for the Forest Dormouse is between May and August, but in warmer areas the season may extend beyond this period.	individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. The RoW within Guzyurdu Forest and ESA 21 will NOT be fenced off temporarily during construction to ensure free passage of large mammals. In addition, the RoW within Guzyurdu Forest will be narrowed to 22m. If any significant length of trench, in terms of interrupting normal paths or passage used by the various species, needs to be left open for more than a few days (72 hours), points of passage will be provided across it at regular intervals (500m).	ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACT** at most to mammals during the construction period where the specified mitigation measures are applied for the seasonal sensitivities identified for each species. **MINOR IMPACTS** Based on the mitigation measures described, the location of BVS-024 away from an ESA and the temporary nature of construction activities, it is predicted that only minor impacts on the biological environment will occur during construction of the access road to BVS-024. This assessment will be confirmed by the site-specific surveys prior to construction. **MINOR IMPACT** Based on the mitigation measures described, the small area of habitat affected in each ESA and the temporary nature of

Environmental Impact Table 25 (Maps 25A and 25B) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	In severe weather, bears hibernate in underground dens or caves. During this hibernation period, the females give birth to one or two cubs (rarely three) in January or February. Following hibernation, bears enter a period of peak feeding in order to recover weight lost during the winter months. During such periods they are known to wander over wide areas and are most likely to come into conflict with human habitation, particularly in remote areas. Females with cubs are at their most aggressive at this time. Potential for disturbance due construction of the new access road for BVS-024 as this length has not be subject to detailed vegetation and faunal surveys. Permanent loss of 350m^2 of montane steppe habitat within each ESA.	Specific requirements have been established in relation to human interaction with the Eurasian Brown Bear – see Section 4.14 of the Mammals Species Dossier (Appendix B1). In the late summer/early autumn, in areas from which bears have been recorded, preconstruction ground surveys will be undertaken to establish the presence of potential hibernation places. If found, construction activity will be restricted to periods outside the hibernation season. Furthermore, in areas where the presence of bears has been confirmed by these surveys, the specific requirements outlined in Section 4.14.5 of Appendix B1 shall be implemented, including education of workers to be alert and aware of the potential for human/bear interactions. Such education will include refuse management on sites (particularly where construction camps are located) and awareness of sensitive periods of the year described previously. The hunting of bears or any other wildlife by the BTC Project personnel or contractors will be strictly forbidden.	construction activities, it is predicted that only minor impacts on the biological environment will occur as a result of construction activities at BVS-025 and BVS-026. This assessment will be confirmed by site-specific surveys prior to construction.

Environmental Impact Table 25 (Maps 25A and 25B) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		The preconstruction survey will establish the presence and local distribution of Wild Goats and Turkish Chamois in the areas from which they have been recorded. Depending on the outcome of these surveys, actions may range from avoidance of construction activity during sensitive periods at specific locations to worker training regarding non-disturbance of nearby herds. Preconstruction surveys of the RoW in the vicinity of river crossings will aim to identify the location and extent of otter holts within the vicinity (250m) of intended river crossings. If discovered these may be cleared in the late summer months under the close supervision of an ecologist approved by BOTAŞ. Preconstruction surveys for the Forest Dormouse of dense woodland in the RoW; if present route clearance will be undertaken during the autumn or winter period. Site-specific vegetation and faunal (including birds) surveys will be	

Environmental Impact Table 25 (Maps 25A and 25B) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		undertaken along the new access road to BVS-024 prior to construction. Based on the findings of this survey, mitigation measures will be identified and implemented as appropriate. However, as BVS-024 is not located within or close to an ESA, it is anticipated that no threatened species will be found. Prior to construction of BVS-025 and BVS-026, a site-specific survey will be undertaken by an ecological specialist to identify and locate threatened species at the site and at any surrounding areas potentially affected by construction activities. Based on the findings of this survey, appropriate mitigation will be determined. The area of sensitive habitat in ESAs 21 and 22 affected by construction activities will be minimised to the minimum necessary for safe working.	

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

MAP 25: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There are two block valve stations.

MAP 25: MAP HIGHLIGHTS

- The pipeline crosses a creek.
- There are numerous access roads that link settlements.
- The pipeline passes the Otlukbeli Mountains.
- Pipeline passes through pasture lands, and small zones of rain fed agriculture and irrigated agriculture land. Approximately 4km of the pipeline route passes through a severely eroded area.

MAP 25: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** four settlements on this map will be directly impacted by the pipeline project (Gunbatur, Guzyurdu, Akdag and Yeniyol) and have land intersected by the pipeline (L). Three of these settlements (Akdag, Guzyurdu and Gunbatur) are also within 500m of the pipeline route, and both Gunbatur and Guzyurdu are located within 2km of the block valve stations. Settlements impacted by traffic have not yet been identified. No settlements are immediately downstream of the pipeline.

- ***Surveyed:*** four settlements (Gunbatur, Guzyurdu, Bindal, Akdag) were surveyed in the field (S) and one settlement (Yeniyol) was surveyed via telephone (T).
- ***Not surveyed:*** Karacaoren (2km north-west of pipeline) was not surveyed.
- ***Disclosure Meeting Location:*** Yeniyol

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Gunbatur (L) (D) (B) (S)			
• ***Demographics:*** 130 inhabitants with 27 households. 20% are Alevi Muslim. • ***Safety****:* the centre of the settlement is situated 500m from pipeline and the nearest house in the settlement is 300m from the pipeline. • ***Project attitude:*** generally positive attitude. Local residents hope that they will benefit from temporary jobs in the construction phase. All people interviewed would like a construction camp to be established close to the settlement. Direct employment is the most likely expected benefit of the pipeline. • ***Land ownership & use:*** 80% of land is privately owned by the local residents and 20% of land is communally owned. Land ownership conflicts have been observed between local residents. Grazing occurs	***Construction hazards: humans.*** Working areas pose safety hazard to residents, particularly small children.	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

conflicts have been observed between local residents. Grazing occurs throughout the year. • ***Settlement livelihood:*** agriculture and forestry are the main sources of livelihood. Key crops include grain and vegetables. Land is irrigated. • ***Availability & skills:*** food services, vehicle drivers, tree fellers, drivers and heavy machinery drivers. 70% of inhabitants would accept a temporary job. • ***Accessibility:*** Roads are of relatively poor quality. They are open year round except for 4-5 days in February and March. • ***Information provision:*** 70% of the population is literate. Best local information provision mechanisms are TV and the Muhtar. • ***Environmental and cultural sites:*** forest. • ***Services:*** there are no sewerage systems and no health care facilities. There is a Gendarme's office and a primary school with one teacher. • ***Infrastructure:*** piped water is supplied to households, however, water supply is irregular. There is no alternative water source. • ***Settlement problems:*** unemployment, poor education and lack of a sewerage system.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Land*** Potential complications in expropriation process. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment	construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. Livestock crossings will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. **See Overview of the Land Acquisition Process in Appendix C9.** Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of the Land Acquisition Process in Appendix C9.** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

	on employment opportunities, potential disruption to utilities, etc.	equal access to information for all residents. This should include emphasising oral communication where literacy is low.	keep this to a minimum.
	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected.**
	Conflict over land boundaries Exacerbation of existing conflicts.	**Land boundaries to remain clearly demarcated** at all times.	**No significant residual impacts.**
	Forestry Loss of a resource used by settlements. Increased expenditure on other fuel sources.	If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure.	**Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.
	Block Valve Station See Environmental Impact Tables and Overview of the Land Acquisition Process in Appendix C9		
SITE SPECIFIC IMPACTS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Guzyurdu (L) (D) (B) (S)			
• ***Demographics:*** there are 450 inhabitants in 100 households.	***Construction hazards: humans***	**Road safety training** will be	**Continued attention** to

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

• ***Safety:*** the centre of the settlement is situated 650m from the pipeline. • ***Health:*** the poor sewerage system has negative implications on health. • ***Disputes:*** there are no disputes. • ***Project attitude:*** the community is generally positive towards the pipeline, although they are also suspicious. In addition, they do not want the pipeline project to interfere with their planned irrigation construction, and they do not want it to pass through the forestry areas near the settlement, they have asked for a change in the pipeline route. • ***Land ownership & use:*** all land is owned privately by local residents. Seasonal grazing takes place in Spring, Summer and Autumn. • ***Settlement livelihood:*** bee keeping is the main economic activity. Animal husbandry and agriculture are also undertaken. Key crops include barley, wheat, legumes and sugar beet. Irrigation occurs, with water sourced from a natural resource north-east of the settlement. • ***Availability & skills:*** the following skills are available; heavy vehicle drivers, tree fellers, drivers and welders. 73% of inhabitants would accept a temporary job. • ***Accessibility:*** 70km to provincial centre. Roads are open except in January, February and March. • ***Information provision:*** 80% of the population is literate. Best information provision techniques are the newspaper and the Muhtar. • ***Environmental & cultural sites:*** forest, thermal spring and graves (graveyard, kurgan, sarcophage, memorial, tomb or gravestone). • ***Services:*** there is no sewerage or waste system. Electricity, water and telephone networks are available. There are no health facilities. There are coffee houses and also a primary school. • ***Infrastructure:*** piped water is available, although supply is not regular. There is no alternative water source. • ***Settlement problems:*** unemployment, education, poor sewerage resulting in spread of disease and lack of markets. • ***Other:*** local residents are very conservative. Caution should be taken by construction workers to avoid inappropriate behaviour.	Working areas pose safety hazard to residents, particularly small children. Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Bees*** Disturbance of any stationary hives located within 300m of the route.	held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Forest Loss of a resource used by settlements. Increased expenditure on other fuel sources.	If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure.	**Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility to information Sectors of the population may not have access to project related information on employment	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

	opportunities, potential disruption to utilities, etc.	for all residents.	
	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected.**
	Conservative settlement Construction workers are more likely to offend inhabitants.	**Any interactions** between construction workers & communities (eg use of local shop) to be carefully monitored. Construction workers to be reminded of the importance of appropriate behaviour in **daily briefings.**	**Low likelihood of significant impacts.** Potential for impacts arising from breeches of rules and procedures. All incidents will be rapidly resolved and used as examples to reinforce procedures.
	Block Valve Station See Environmental Impact Tables and Overview of the Land Acquisition Process in Appendix C9		
SITE SPECIFIC IMPACTS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Bindal (S)			
• ***Demographics:*** 300 inhabitants with 50 households • ***Safety****:* the centre of the settlement is situated 2500m from pipeline. • ***Project attitude:*** there is generally a positive attitude towards the pipeline, although the local residents are concerned that construction activities will damage their road. They are also concerned about accidents occurring during construction, especially involving children. All nine households surveyed would like a construction camp to be	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

All nine households surveyed would like a construction camp to be established close to the settlement. Direct employment is the most widely expected benefit of the pipeline. • ***Land ownership & use:*** all land is privately owned by local residents. Seasonal grazing of livestock takes place during Spring, Summer and November. • ***Settlement livelihood:*** predominantly agriculture, with grain, herbs, sugar beet and fruit trees grown; and a small amount of bee keeping. Some land is irrigated. • ***Availability & skills:*** available skills are food services personnel, heavy vehicle drivers, tree fellers and drivers. 55% of people are willing to accept a temporary job. • ***Accessibility:*** 50km to provincial centre. Roads are always open and are of relatively good quality. • ***Information provision:*** 75% of the population is literate. The most commonly used sources of information are TV, newspaper, and via telephone. • ***Environmental & cultural sites:*** there is a mausoleum, a thermal spring and a forest. • ***Infrastructure:*** piped water is available year round. There is no alternative water source. Electricity, and telephone networks are available. There is no sewerage system • ***Services:*** the settlement has a primary school and one teacher, but no health facilities. • ***Settlement problems:*** unemployment.	***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
SITE SPECIFIC IMPACTS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Akdag (L) (D) (S)			
• ***Demographics:*** 150 inhabitants with 40 households. • ***Safety****:* the centre of the settlement is situated 900m from pipeline and the nearest house in the settlement to the pipeline is 350m. • ***Project attitude:*** there is no hostility to pipeline and there is a positive attitude towards the project, although the local residents do not want	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children.	**Road safety training** will be held in schools prior to construction commencing. **Community liaison**	**Continued attention** to mitigation measures will be critical to prevent injury.

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

the pipeline to affect their pasture land, forestry areas or their roads. The majority (10/11) of people interviewed would like a construction camp to be established near to the settlement. Direct employment is the most expected benefit of the pipeline. • ***Land ownership & use:*** mainly private ownership (80%). Wheat and barley are cultivated and irrigation occurs. Seasonal grazing occurs in Spring and Summer. • ***Settlement livelihood:*** bee keeping is the main economic activity. Considerable agriculture also occurs. • ***Available skills:*** main skills available are food service personnel, heavy vehicle drivers, tree fellers, drivers and welders. 46% of people would be willing to accept a temporary job. • ***Settlement accessibility:*** 40km to provincial centre and 40km to district centre. The roads are always open and are in a relatively good state of repair. • ***Information provision:*** 95% of the population is literate. • ***Services:*** electricity networks available. No waste disposal system, nor any health facilities. There is a primary school with one teacher. • ***Infrastructure:*** piped water is supplied to households. The supply is regular. There is no alternative water source. • ***Settlement problems:*** waste disposal	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Bees*** Disturbance of any stationary hives located within 300m of the route.	**meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move them to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original	**Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

		location.	complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Forest Loss of a resource used by settlements. Increased expenditure on other fuel sources.	If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable**	**Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.

Social Impact Table 25 (Map 25C) (KPs 463.1 – 485.1): Otlukbeli Mountains and Guzyurdu Forest, Erzincan Province

		compensation. The level of compensation will be facilitated by the Projects complaints procedure.	

Environmental Impact Table 26 (Maps 26A and 26B) (KPs 485.1 – 505.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Lithic Sandy-skeletal Cryochrepts along ridge summits. • Fine-loamy Typic Cryorthents in valley bottoms.	Soil related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Main potential impacts: • soil erosion; • sediment yield; • soil productivity; • channel alteration.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.

Environmental Impact Table 26 (Maps 26A and 26B) (KPs 485.1 – 505.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Crushed rock. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	
Landscape and Visual			
The western mountains rise higher and the route passes into the true alpine zone peaking at 2,810m asl, where the snow still lies late into June. The landscapes here are desolate, sparsely vegetated, and angular with far-reaching vistas over neighbouring mountain ranges. The landscape is outstanding but remote and little visited and is previously scarred by the telecommunications station in this section and the un-reinstated natural gas pipeline. The diverse landform may offer opportunities to screen the route.	• Alpine vegetation in the western part of the Otlukbeli Mountains is extremely vulnerable to long-term damage because of the shallow, poor soils, and the extreme climatic conditions. • Visual liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline. • Elevation means that short growing season and cool temperatures will delay reinstatement. • Construction alongside mountain tracks will be visually conspicuous.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. Elsewhere **MODERATE IMPACTS** as high elevation grasslands may prove difficult to reinstate. Even with care, the visual impact can be expected to remain up to five years after construction has been completed.

Environmental Impact Table 26 (Maps 26A and 26B) (KPs 485.1 – 505.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Measures to reduce the impact of heavy machinery will include use of moveable equipment mats to spread vehicle weight and avoid deep rutting. The possibility of undertaking construction during early spring when the ground is still snow-covered and frozen will be investigated since this technique is used successfully in arctic tundra environments. At such times it may be possible to lift frozen turfs (impossible in the summer because of low root mass and friable soils) and replace them with little damage. If this is not possible, implement trials using reinstatement species and very low doses of quick-release fertilisers (NPK + micro-nutrients).	
Groundwater			
The pipeline route passes over springs on the Erzincan Plateau, which is a major groundwater resource used for drinking water by settlements in the vicinity of the route between KP 488 to the end of this section.	Potential for moderate and localised impacts to groundwater quality from	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and	**MODERATE IMPACT** This area is a major groundwater resource,

Environmental Impact Table 26 (Maps 26A and 26B) (KPs 485.1 – 505.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	construction activities.	conflicting with other users, including: • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	although its Class is not known at this stage. However, where mitigation measures described are applied, impacts are predicted to be moderate at most and localised. Strict adherence to the mitigation measures contained in the EMMP (Appendix C1) and PPP (Appendix C4) will be required.
Ecology			
Protected Areas Route passes south of the Kelkit Wildlife Protection Area (22,000 ha) , passing within 130m at its closest point KP 493.8, but does not cross the protected area. The area was established in 1983 to protect the Turkish Chamois and Wild Goat.	Although the pipeline route does not cross the protected area, there is a potential for disturbance if construction workers stray over the protected area boundaries.	Hunting of the Turkish Chamois and the Wild Goat by construction workers will be prohibited and enforced. Apply standard mitigation measures as described in Section 6.6, including ensuring workers keep within the RoW at all times, ensuring construction vehicles keep to approved roads and avoid off-road driving of vehicles.	**MINOR IMPACT** Only minor impacts on the basis of avoidance and strict adherence to project mitigation measures.
Important Ecological Factors ESA 23 is identified between KP 485.0 and KP 485.5 for a nationally-threatened plant species. The IUCN status for this species is given in Table 5.20, Section 5. ESA 24 occupies a total length of c. 24.1km of the route between KP 487.1 and KP 511.2 and continues on to Map 27B. Eight globally-threatened plant	Habitat destruction of the alpine zone may result in the loss of individuals from populations of globally-threatened plants and habitat destruction of montane steppe	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 23 & 24. The feasibility of translocating species will be assessed prior to	**MODERATE IMPACTS** Medium-term disturbance to internationally important flora and supporting habitats. Mitigation measures will minimise losses but because of the fragility of the habitat,

Environmental Impact Table 26 (Maps 26A and 26B) (KPs 485.1 – 505.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
species occur within this ESA (*Gypsophila aucheri, Arenaria pseudacantholimon, Festuca anatolica var. borealis, Paracaryum corymbiforme, Ranunculus sintenisii, Dianthus zederbaueri, Consolida olopetala* and *Minuartia anatolica var. scleranthoides*). The IUCN status for these species are given in Table 5.20, Section 5. Because of the fragility of this alpine zone ecosystem, ESA 24 has been extended to include the entire alpine habitat occurring along the pipeline route. At KP 497.5, 1 Black Kite (nationally-threatened) was recorded. The protection status for this species is given in Table 5.21, Section 5. BVS-027 and BVS-028 will be located at KP 487.7 and KP 499.1, respectively, within alpine zone habitat in ESA 24. Approximately 350m^2 of permanent landtake required for each BVS. New access roads will be constructed to each site, of c. 45m in length to BVS-027 and c. 134m to BVS-028.	may result in the loss of individuals from nationally-threatened plants populations. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss, if construction is undertaken during the breeding season (ie between March and July inclusive). July can remain sensitive for late and second broods. Permanent loss of 350m^2 of alpine zone habitat in ESA 24 during construction of the BVS sites.	construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly. • turfs containing the threatened plants to be nurture until replacement. Care will be taken in using fertiliser during re-instatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESAs 23 & 24. Additionally, the fragility of the alpine zone requires measures to be taken to reduce the impact throughout. The feasibility of using techniques to reduce the effects of heavy machinery will be investigated including limits on axle weights, the use of balloon tyres, the prohibition of tracked vehicles, and the use of geo-	disturbance effects may still be detectable after several years. **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to March, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACT** Based on the mitigation measures described, the small area of habitat affected and the temporary nature of construction activities, it is predicted that only minor impacts on the biological environment will occur as a result of construction activities at BVS-027 and BVS-028. This assessment will be confirmed by site-specific surveys prior to construction.

Environmental Impact Table 26 (Maps 26A and 26B) (KPs 485.1 – 505.1): Otlukbeli Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		textiles to line roadways. Preconstruction survey for evidence of past Black Kite nesting sites. If nesting sites are found within the RoW these will be removed prior to March and after July; where those within 250m of the RoW are observed in April and if nesting is occurring, construction will be avoided until July. Prior to construction of BVS-027 and BVS-028, a site-specific survey will be undertaken by an ecological specialist to identify and locate threatened species at the site and at any surrounding areas potentially affected by construction activities. Based on the findings of this survey, appropriate mitigation will be determined.	

Social Impact Table 26 (Map 26C) (KPs 485.1 – 505.1): Otlukbeli Mountains, Erzincan Province

MAP 26: PROJECT INFORMATION
There are no pump stations or construction camps in the area. There are two block valve stations.
MAP 26: MAP HIGHLIGHTS
• Predominant land uses are pasture, grazing, forestry and some irrigated agriculture. • Forest areas occupy the western boundary of part of the corridor. • Summits of narrow prominent ridges dominate the landscape.
MAP 26: IMPACTED & SURVEYED SETTLEMENTS
• ***Impacted**:* no settlements will be directly impacted by the pipeline project. None of these have land intersected by the proposed pipeline, none are within 5km of a pump station, none are within 2km of the block valve stations, and no settlements are within 500m of the pipeline route. Settlements impacted by traffic have not yet been identified. No settlements are downstream of a river/ creek crossing. • ***Not surveyed:*** three settlements on the map were not surveyed: Komur (2.65km from the pipeline); Kirmana (2.9km from the pipeline); and Kocyatagi (2.8km from the pipeline). These, however, are all more than 2km from the pipeline.

Environmental Impact Table 27 (Maps 27A and 27B) (KPs 505.1 – 526.5): Kara Mountain area, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Lithic Sandy-skeletal Cryochrepts along ridge summits. • Mesic Coarse-silty Typic Xerochrepts on lower slopes, especially below 2,000m. • Channel gravel and boulders along fluvial headwaters.	Soil related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Main potential impacts: • soil erosion; • sediment yield; • soil productivity; • frost heave (fine soils at elevation above 2,000m); • channel alteration.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.

Environmental Impact Table 27 (Maps 27A and 27B) (KPs 505.1 – 526.5): Kara Mountain area, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Crushed rock. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Bury pipe below 1m depth. • Channel stabilisation - see typical drawings.	
Landscape and Visual			
The route continues through the true alpine zone. The landscapes here are desolate, sparsely-vegetated, and angular with far-reaching vistas over neighbouring mountain ranges. Landscape quality is outstanding although remote and little visited. The landscape is also previously scarred by the telecommunications station in this section and the poorly reinstated NGP. From about KP 508, the Pipeline descends sharply along gravely hillsides and grassy valleys to the flat valley of Ilgar Creek where it crosses electricity transmission lines and a major highway. Landscapes characterised by cropland with river banks covered by dense bushes and trees. BVS-029 will be located at KP 520.0 within coniferous forest. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to this site of c. 35m in length.	Visual related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline. Alpine vegetation in the western part of the Otlukbeli Mountains is extremely vulnerable to long-term damage because of the shallow, poor soils, and the extreme climatic conditions. Elevation means that short growing season and cool temperatures will delay reinstatement. Potential impacts and their management during BVS	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular,	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. Elsewhere **MODERATE IMPACTS** as high elevation grasslands may prove difficult to reinstate. Even with care, the visual impact can be expected to remain up to five years after construction has been completed. **MODERATE TO MINOR IMPACTS** on lower lying cropland where re-vegetation will be easier to achieve.

Environmental Impact Table 27 (Maps 27A and 27B) (KPs 505.1 – 526.5): Kara Mountain area, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	construction will be the same as those during pipeline construction.	specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Measures to reduce the impact of heavy machinery will include use of moveable equipment mats to spread vehicle weight and avoid deep rutting. The possibility of undertaking construction during early spring when the ground is still snow-covered and frozen will be investigated since this technique is used successfully in arctic tundra environments. At such times it may be possible to lift frozen turfs (impossible in the summer because of low root mass and friable soils) and replace them with little damage. If this is not possible, implement trials using reinstatement species and very low doses of quick-release fertilisers (NPK + micro-nutrients).	
Surface Geology and Geohazards			
Faults Route crosses the North Anatolian Fault zone twice (KP 507.5 and 508.5).	See *Section 8*.	See *Section 8*.	See *Section 8*.

Environmental Impact Table 27 (Maps 27A and 27B) (KPs 505.1 – 526.5): Kara Mountain area, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Fault is class A and the fault zone is c. 500m wide at the crossing point. Route crosses the fault zone in an area that has a series of well-developed pressure ridges c. 490m wide. There are four main splays within this zone, which are considered as sympathetic faults that will slip only during an earthquake on the main fault trace; they are not likely to produce earthquakes independently.			
Surface Waters			
The route crosses Bulgurcayiri Creek (KPs 521.1 – 522.3). Bank vegetation and floodplain of creek are disturbed by construction of the NGP. The route also crosses the Ilgar River at the end of this map, which is discussed on the following Environmental Impact Table 28 (see Map 28A).	Disturbance to Bulgurcayiri Creek, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Potential for long-term sedimentation and turbidity. The NGP lies adjacent and parallel to the river.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at this watercourse crossing impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation	**INDIRECT POSITIVE IMPACT** where the Bulgurcayiri Creek crossing previously disturbed during construction of the NGP is reinstated. **MINOR IMPACTS** Although the water quality classification for Bulgurcayiri Creek is unknown, only minor impacts expected, as disturbance will be limited to the immediate working area. Sedimentation of Bulgurcayiri Creek will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 27 (Maps 27A and 27B) (KPs 505.1 – 526.5): Kara Mountain area, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity at the Bulgurcayiri Creek crossing point, including sediment filters/trapping devices, settling ponds and trench de-watering.	
Groundwater			
The pipeline route continues to pass over springs on the Erzincan Plateau from the beginning of the section to KP 518.6.	Potential for moderate and localised impacts to groundwater quality from construction activities.	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	**MODERATE IMPACT** This area is a major groundwater resource, although its Class is not known at this stage. However, where mitigation measures described are applied, impacts are predicted to be moderate at most and localised. Strict adherence to the mitigation measures contained in the EMMP (Appendix C1) and PPP (Appendix C4) will be required.
Ecology			
Important Ecological Factors ESA 24 continues for c. 6.25km on this map (see Environmental Impact Table 26 and Map 26B for previous description of species). ESA 25 and 26 occur between KP 522.3 and KP 522.8 and between KP 525.0 and KP 525.6, respectively. These ESA are identified for the globally-threatened plant species *Barbarea auriculata var. paludosa* occurring within ESA 25 and the globally-threatened *Gypsophila aucheri* within ESA 26. The IUCN status for these species are given in Table 5.20, Section 5.	Habitat destruction of the alpine meadow, wet meadow or the areas peripheral to cultivated lands may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 25 & 26. Diligence will be exercised in searching for *Acer divergens var. trilobium* in the forest between KPs 519.7 – 520.1. The feasibility of translocating species will be assessed prior to	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2).

Environmental Impact Table 27 (Maps 27A and 27B) (KPs 505.1 – 526.5): Kara Mountain area, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
One Imperial Eagle (globally-threatened) was recorded at c. 1km north-west of KP 517. Near KP 523.5, 1 Whinchat and 1 Bluethroat (both nationally-threatened) were recorded, and another 2 Bluethroat were recorded at KP 523.8. At the Ilgar River crossing, 1 Dipper and 1 Barred Warbler (both nationally-threatened) were recorded. The protection status for these species are given in Table 5.21, Section 5. Field investigations undertaken in mid-2002 have determined that the re-routed section (necessitated by geohazard considerations) is a continuation of ESA 24.	to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during reinstatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 24. Preconstruction survey will establish the presence of mature trees and rock ledges within 500m of the pipeline route for the Imperial Eagle. If nesting sites are identified, avoidance of construction activity from April to July. Shrubs and dense vegetation	**MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Environmental Impact Table 27 (Maps 27A and 27B) (KPs 505.1 – 526.5): Kara Mountain area, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		along the RoW will be cleared outside the breeding season for the Whinchat. Clearance of riverside trees, shrubs and thickets in advance of the construction of the Bulgurcayiri Creek and Ilgar River crossings to be undertaken outside the April – July period for the Bluethroat and Barred Warbler. Preconstruction surveys will establish whether suitable Dipper nesting sites are available within 250m of the Ilgar River crossing. If this is the case, construction activity is to be avoided between April and July.	

Social Impact Table 27 (Map 27C) (KPs 505.14 – 526.5): Kara Mountain area, Erzincan Province

MAP 27: PROJECT INFORMATION
There are no pump stations or construction camps in the area. There is one block valve station.
MAP 27: MAP HIGHLIGHTS
• Pasture and rain fed agriculture are the predominant land uses. • Topography is steep, numerous springs emerge along the slopes • The route follows the summit of an east west ridge
MAP 27: IMPACTED & SURVEYED SETTLEMENTS
• ***Impacted****:* no settlements will be directly impacted by the pipeline project. None of these have land intersected by the proposed pipeline; none are within 5km of a pump station; none are within 2km of the block valve station, and no settlements are within 500m of the pipeline route. Settlements impacted by traffic have not yet been identified. No settlements are downstream from a river/ creek crossing. • ***Surveyed:*** there are no settlements within 2km of the pipeline.

Environmental Impact Table 28 (Maps 28A and 28B) (KPs 526.5 – 547.4): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Fine-loamy to Loamy-skeletal shallow Typic Xerochrepts on sloping lands and some valley bottoms. • Mesic Typic Calcixerolls on valley bottoms. • Channel cobbles and other sediments on fluvial lands. • Typic Mesic Xerorthents along valley bottoms.	Soil related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. Main potential impacts from BTC Pipeline construction on hills include: • soil erosion; • sediment yield; • soil productivity. Potential impacts on flat and undulating land include: • soil erosion; • sediment yield; • soil productivity; • channel alteration; • water-logged soils and compaction.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on hill slopes and in areas of rill and gully development. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). • Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils.	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Soil productivity losses are predicted to last less than 3 months after construction is completed.

Environmental Impact Table 28 (Maps 28A and 28B) (KPs 526.5 – 547.4): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Crushed rock. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Apply equipment mats as appropriate.	
Landscape and Visual			
Undulating, valley bottom landscape bound by low hills. Irrigated agriculture is the predominant landuse. The poorly reinstated NGP significantly detracts from the landscape along this section. The NGP diverges from the Ilgar River at KP 530. This location is characterised by a fluvial landscape, where river cobbles, gravel, and sand occupy a shallow, parabolic channel. Infrequent, thin forests occur on sloping lands either side of the route. Grazing dominates the land use. Highway 100 runs parallel with the BTC Pipeline route for some 10km before diverging along with the NGP. Further west as the route turns south, the landscape quality increase. The poorly drained valley bottoms are a mixture of cropland and expansive wet meadows with broad-leaved trees and the hills on the southern side are thickly forested with Scot's Pine. Small settlements lie 3 to 4km apart on well-drained, shallow slopes that fringe the valley bottoms. BVS-031 will be located at KP 547.0 on cultivated land. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 25m in length.	Visual related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel The wet marshland between the Suvarin Creek and Ilgar River will show a long-term/ permanent scar unless care is taken with heavy machinery. Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MODERATE IMPACT** during the short-term in the more sensitive landscape west of KP 530.

Environmental Impact Table 28 (Maps 28A and 28B) (KPs 526.5 – 547.4): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).Apply 'Soils' reinstatement specifications above.	
Surface Waters			
Two watercourses are crossed by the route in this section: • Ilgar River crossed five times (near KP 525.4, between KPs 529.8 – 531.1, KPs 531.1 – 531.6, KP 533.0 and near KP 535.0). BVS-030 will be located at KP 532.0 and c. 120m from Ilgar River. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 50m in length. • Buyuk Creek (KPs 534.5 – 535.0). Buyuk Creek is a right-bank tributary of Ilgar River. The BTC Pipeline crossing point is c. 25m from the NGP crossing of this creek.	The NGP lies adjacent and parallel to the river. Disturbance to Ilgar River and Buyuk Creek, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Potential for long-term sedimentation and turbidity.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at these watercourse crossings impacted by the presence and proximity of the NGP. Responsibilities between the	**INDIRECT POSITIVE IMPACT** where these watercourse crossings previously disturbed during construction of the NGP are reinstated. **MINOR IMPACTS** Although the water quality classifications for these watercourses are unknown, only minor impacts expected during both pipeline and BVS construction, as disturbance will be limited to the immediate working area. Sedimentation of both watercourses crossed in this section will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 28 (Maps 28A and 28B) (KPs 526.5 – 547.4): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity during crossing of these watercourses, including sediment filters/trapping devices, settling ponds and trench de-watering.	
Ecology			
Important Ecological Factors Four nationally-threatened birds were recorded from this section: • Whinchat: 3 at KP 530.6, 2 at Aktas Creek crossing, 1 at Ilgar River crossing, 12 at KP 543.2, and 3 at KP 536.9; • Barred Warbler: 1 at Aktas Creek crossing, 3 at Ilgar River crossing, and 4 near KP 536.9; • Dipper: 1 adult and 1 juvenile at Ilgar River crossing; • Booted Eagle: 1 near KP 536.9. The protection status for these species are given in Table 5.21, Section 5. ESA 51 (KP 528.20-529.20) is identified for a range of endemic flora species (including the national threatened endemics, *Helychrysum arenarium spp. erzincanicum* and *Ebenus macrophylla*).	Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive, although the Booted Eagle begins breeding as early as March). July can remain sensitive for late and second broods. Habitat destruction of arid sand-gravel meadows may result in the loss of individuals from populations of nationally-threatened endemics.	Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Whinchat. Clearance of riverside trees, shrubs and thickets in advance of the construction of the Aktas Creek and Ilgar River crossings to be undertaken outside the April – July period for the Bluethroat and Barred Warbler. Preconstruction surveys will establish whether suitable Dipper nesting sites are available within 250m of the Ilgar River crossing. If this is the case, construction activity is to be avoided between April and July.	**MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April (March for the Booted Eagle), and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MODERATE IMPACTS** due to short-term disturbance to important flora within the ESA 51. The Construction Contractor will ensure that

Environmental Impact Table 28 (Maps 28A and 28B) (KPs 526.5 – 547.4): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Preconstruction surveys will establish the presence of potential nesting sites for the Booted Eagle within 500m of the pipeline route. If nesting sites are identified, avoidance of construction activity from March to July. Threatened plant species will be identified and located during pre-construction surveys within ESA 51. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW.	construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2).

Environmental Impact Table 28 (Maps 28A and 28B) (KPs 526.5 – 547.4): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Archaeology and Cultural Heritage			
Bakacak (3rd Degree Site*) – flat settlement located within the 100m Corridor. Although, no architectural remains were found within this settlement, Prehistoric ceramic shards have previously been found here. Akcakoy (3rd Degree Site*) – flat settlement, located to the south-east of the pipeline route. No architectural remains are visible as a result of agricultural activities. Based on the ceramics pieces observed on the surface, this is probably a Roman settlement. * These sites have not yet been registered by the MoC and are provisionally assigned these classifications. Bakacak and Akcakoy have been proposed for registration by the regional preservation council	Potential for sites to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of these sites.	The pipeline has been re-routed to avoid Bakacak flat settlement. Akcakoy will be delineated to avoid accidental damage during construction and fenced throughout the construction period. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Assuming Akcakoy is fenced, impacts will be limited to the temporary disturbance of the site setting and peripheral features. **MINOR IMPACTS** at most at Bakacak, which will be limited to the temporary disturbance of the site setting and peripheral features.

Social Impact Table 28 (Map 28C) (KPs 526.5 – 547.4): Kose Mountains, Erzincan Province

MAP 28: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There are two block valve stations.

MAP 28: MAP HIGHLIGHTS

- Undulating valley bottom landscape with low hills and a high water table in places.
- The route crosses four land uses types, the predominant uses being agriculture and rainfed agriculture.
- Other land uses include non-agricultural land, pasture and forests.
- The pipeline crosses four creeks (Sancipinar, Suvarin, Buyuk and Aktas) and the IIgar River.

MAP 28: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted**:* five settlements will be directly impacted by the pipeline project. Four of these have land intersected by the proposed pipeline (Alacaatli/ Alacati, Sahverdi, Kalkanci and Hacikoy) (L), and two settlements (Bakacal Mah and Alacaatli/Alacati) are within 500m of the pipeline route (D). Three settlements (Melikserif, Alacaatli and Belensor) are within 2km of the block valve stations (B). No settlements are within 5km of a pump station. Settlements impacted by traffic have not yet been identified. One settlement is downstream of a river (Sipdigin is 2.5km downstream of River Llgar).

- ***Surveyed**:* four settlements (Alacaatli/ Alacati, Sahverdi, Kalkanci and Hacikoy) were surveyed by telephone (T).
- ***Not surveyed:*** seven settlements have not been surveyed: Melikserif (2km from the pipeline); Bakacal Mah (300m from the pipeline); Hanzar (1.6km from the pipeline); Ekrek (2km from the pipeline); Sipdigin (1.65km from the pipeline); Huseyinsih (1.7km from the pipeline); and Belensor (650m from the pipeline).
- ***Disclosure Meeting Location:*** Alacaatli

SITE SPECIFIC IMPACTS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Alacaatli/ Alacati (D) (L) (B) (T)			
• ***Demographics**:* 220 inhabitants. There has been an increase in population over the past five years. 50% of the population migrates seasonally. • ***Safety:*** the settlement centre is 500m from the pipeline, and the nearest house is 150m from the pipeline. • ***Project attitude:*** a construction camp would be welcome. There is general awareness of the pipeline, although the main concern is that the inhabitants do not have enough information about the pipeline. • ***Land ownership & use:*** 60% of the land is communally owned and used. There is temporary irrigation. • ***Settlement livelihood:*** agriculture and forestry are main sources of	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Environmental Impact Table 29 (Maps 29A and 29B) (KPs 547.4 – 571.0): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Loamy-skeletal Typic Xerochrepts and Micro Xerochrepts on most sloping lands. • Stony land along ridge summits. • Cryic or mesic Typic Calcixerolls on soils formed on gently sloping to sloping lands from limestone or marl. • Aquic Xerorthents in highland swales with high water tables.	Main potential impacts on hills include: • soil erosion; • sediment yield; • soil productivity. Potential impacts on flat land and undulating land include: • soil erosion; • sediment yield; • soil productivity; • channel alteration; • water-logged soils and compaction; • frost heave (in upland valley bottoms).	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Use equipment mats as appropriate.	**MINOR IMPACT** Soil productivity losses are predicted to last less than 3 months after construction is completed. Furthermore, soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
Route passes south of Refahiye across flat plateau lands and rolling farmed hills before ascending sharply from the valley floor at about 1,650m asl into the Tecer Mountains at 2,100m asl and then less steeply to above 2,300m asl. The wild landscapes here are of high quality, with craggy mountains, and broad grassy valleys, occasionally scattered with pines and, beyond the route, more extensive forests. Grazing is widespread and scattered summer migrant herder's settlements are evident. Further west the mountain scenery becomes more dramatic with sharp ridges and montane steppe interspersed with exposures of the whitish underlying marl, whose poorer soils support a diverse if sparse flora. BVS-032 will be located at KP 550.6 within plain steppe habitat. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 20m in length. Bekolar settlement lies	Medium to long-term visual impact where the route cuts through thin Calcixerolls to expose the underlying marl, which will persist as a whitish cast across the landscape. Short-term visual impact on non-marl portions of the route. Landform presents screening opportunities. Potential for short-term visual	Apply 'Soils' reinstatement specifications above, especially where topsoil is sufficiently thick to reinstate. Attempt high rate of fertilisation using NPK + micro-nutrients with mulching such as coir fibre. Particular attention will be paid to the control of dust, noise and traffic during construction at BVS-032.	**MAJOR TO MODERATE IMPACT** Where reinstatement is unlikely to be fully effective in areas where the corridor overlies marl, it will retain its whitish colour and show as a white line across a distinct upland landscape. This impact is reduced in the more exposed rocky terrain of the summit where vegetation loss may not be so pronounced. However, a number of

Environmental Impact Table 29 (Maps 29A and 29B) (KPs 547.4 – 571.0): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
c. 310m from the site.	impact during construction of BVS-032 for villagers in Bekolar.		additional site-specific mitigation measures will further be employed in tuff areas to manage the above impact, including: • soil survey prior to construction to determine topsoil thickness at regular intervals and topsoil depth; • site-specific topsoil layer removal and monitoring during storage; • soils specialist in attendance throughout topsoil removal, storage and reinstatement; • post-reinstatement monitoring. **MINOR IMPACT** Given the relatively small size of the block valve station and the temporary nature of construction activities, impacts are anticipated to be minor subject to implementation of the specified mitigation measures.
Noise			
Bekolar settlement is located c. 220m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Bekolar settlement during soil stripping activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery;	**MINOR IMPACT** During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise

Environmental Impact Table 29 (Maps 29A and 29B) (KPs 547.4 – 571.0): Kose Mountains, Erzincan Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.

Social Impact Table 29 (Map 29C) (KPs 547.4 – 571.068): Kose Mountains, Erzincan Province

MAP 29: PROJECT INFORMATION
There are no pumps or construction camps in the area. There is one block valve station.
MAP 29: MAP HIGHLIGHTS
• Predominant land use is pasture. There are some areas of irrigated agricultural land, rain fed agriculture and non-agricultural land. • Conservation forests occupy the ridges each side of the pipeline route.
MAP 29: IMPACTED & SURVEYED SETTLEMENTS
• ***Impacted**:* one settlement will be directly impacted by the pipeline project (Bekolar). It is within 500m of the pipeline route (D) and within 2km of the block valve station (B), however it does not have land intersected by the proposed pipeline. There are no settlements within 5km of a pump station. Settlements impacted by traffic have not yet been identified. No settlements are downstream of a pipeline river/ creek crossing. • ***Not surveyed:*** six settlements were not surveyed: Divir (1.5km from the pipeline), Bekolar (Arpayazi) (300m from the pipeline), Gavurdu, Yukarimaden Mah (1.4km from the pipeline), Asagimaden (1.75km from the pipeline) and Kocu (1.8km from the pipeline).

Environmental Impact Table 30 (Maps 30A and 30B) (KPs 571.0 – 590.2): Kose Mountains, Sivas/Erzincan Province Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Cryic or mesic Typic Calcixerolls on soils formed on gently sloping to sloping lands from limestone or marl. • Loamy-skeletal Shallow (or Micro) Xerochrepts on moderately steep and steep lands. • Aquic Xerorthents in highland swales with high water tables.	Main potential impacts: • soil erosion; • soil productivity; • waterlogging and compaction (in upland swales with high water tables). Other potential impacts include: • sediment yield; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Crushed rock. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Employ equipment mats.	**MINOR IMPACT** Soil productivity losses are predicted to last less than 3 months after construction is completed. Furthermore, soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. In areas with a high water table, water is predicted to remain in surface depressions for less than 3 months after construction.
Landscape and Visual			
The sharp ridged mountainous landscape continues with the montane steppe interspersed with exposures of the whitish flower-rich marl. The route dips but rises again to peak at 2,370m asl passing briefly back into the alpine zone on the tops of the barren rounded mountains where extensive views of the mountainscapes are obtained – contrasting umber and grey soils set off by the greens of the mountain meadows and fragmented pine forests below. Despite its wilderness character, this landscape, with a sparse if diverse flora, is more tolerant of change. Telecommunication masts and the un-reinstated NGP, (which converges with the route at KP 574), cause significant visual intrusion. From here the route descends sharply into the Kizilirmak valley at about 1,700m asl.	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. May be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. Visual liabilities of the NGP, which was not reinstated, are potentially exacerbated by the	Difficult to mitigate except where topsoil is sufficiently thick to reinstate. Attempt high rate of fertilisation using NPK + micro-nutrients with mulching using coir fibre or equivalent. It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-	**INDIRECT POSITIVE IMPACT** in areas where the BTC and the NGP corridors are reinstated. **MODERATE IMPACT** Where reinstatement is unlikely to be fully effective in areas where the corridor overlies marl, it will retain its whitish colour and show as a white line across the

Environmental Impact Table 30 (Maps 30A and 30B) (KPs 571.0 – 590.2): Kose Mountains, Sivas/Erzincan Province Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	BTC Pipeline, where their RoWs lie adjacent or closely parallel.	phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2).	landscape. This impact is reduced in the more exposed rocky terrain of the summit where vegetation loss may not be so pronounced.
Noise			
Kasaplar settlement is located c. 215m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Kasaplar settlement during soil stripping activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels;	**MINOR IMPACT** During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.

Environmental Impact Table 30 (Maps 30A and 30B) (KPs 571.0 – 590.2): Kose Mountains, Sivas/Erzincan Province Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	

Social Impact Table 30 (Map 30C) (KPs 571.0 – 590.2): Kose Mountains, Sivas/Erzincan Province Border

MAP 30: PROJECT INFORMATION			
There are no pump stations, construction camps or block valve stations in the area.			
MAP 30: MAP HIGHLIGHTS			
• The predominant land use types are pasture and rain-fed agriculture. • Uplands and mountainous landscape with high water tables. • Forests and dense grasslands occupy the sloping land. • The pipeline crosses three creeks (Kandil, Hishis and Kanezier)			
MAP 30: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted**:* eleven settlements (Kandil, Tuzlucayir, Tescil Harici, Yurtbasi, Tecknecik, Avsarozu, Gunyuzu, Arpayazi, Mandandere, Kasaplar and Aydin) will be directly impacted by the pipeline project. All of these have land intersected by the proposed pipeline (L). No settlements are within 5km of a pump station, or within 2km of a block valve station. Two settlements (Kasaplar, Yurtbasi) are within 500m of the pipeline route (D). Settlements impacted by traffic have not yet been identified. Three settlements are downstream of a river/creek crossing (Kasaplar is downstream of the Kanezler Creek, Tuzlucayir is downstream of the Hishis Creek and Kandil is downstream of the Kandil Creek). • ***Surveyed**:* one settlement (Yurtbasi) was surveyed in the field (S) and ten settlements (Kandil, Tuzlucayir, Tescil Harici, Tecknecik, Avsarozu, Gunyuzu, Arpayazi, Mandandere, Kasaplar and Aydin) were surveyed by telephone (T). • ***Not on the map:*** seven settlements are not on the map (Tescil Harici, Yurtbasi, Tecknecik, Avsarozu, Gunyuzu, Arpayazi, Mandandere).			
SITE SPECIFIC IMPACTS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Yurtbasi (L) (D) (S)			
• ***Demographics**:* 2,200 inhabitants with 180 households. There has been an increase in population recently, due to the return of the unemployed and pensioners that relocated after the 1992 earthquake. • ***Safety:*** the settlement centre is 700m from the pipeline and the nearest house is 150m. • ***Project attitude:*** a construction camp would **not** be welcomed (by four out of 11 inhabitants interviewed) and the overall opinion of the project is **negative**, because the pipeline passes through the new area of the settlement, which is still in its development phase. In	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings. **Protective barrier fencing**	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 30 (Map 30C) (KPs 571.0 – 590.2): Kose Mountains, Sivas/Erzincan Province Border

addition, a previous project resulted in damage to land and compensation payments were insufficient. 27% of inhabitants are concerned about noise and dust. • ***Land ownership & use:*** 20% of land is owned by local residents and 80% is communal. Land owners have title deeds. There is a diverse range of livestock and there is seasonal grazing in Spring, Summer and November. The key crops cultivated are grain and sugar beet. Some land is irrigated using permanent channels. • ***Settlement livelihood:*** agriculture is the main source of livelihood and cereals and sugar cane are cultivated mainly for subsistence. Cattle, sheep breeding and bee keeping also take place. 50% of inhabitants are family labourers. • ***Availability & skills:*** local residents have had previous pipeline experience. Four out of 24 possible construction skills including typesetting, drivers, heavy machinery drivers, food service personnel and construction workers are available. 37% are willing to accept temporary jobs. • ***Accessibility:*** dirt roads, accessible in the winter. The settlement is 15km from the district centre. • ***Information provision:*** All inhabitants are literate. • ***Services*****:** support services for farmers (agricultural co-operatives) are present along with sports facilities, a Library, market and transport facilities. There is a primary school with one teacher and a nurse. • ***Infrastructure*****:** there is a piped, regular supply and no alternative sources are used. There are no water mains in the new settlement area of the settlement. Electricity and sewerage systems are present and there are no waste systems. The main form of waste disposal is through recycling or mixing with fertilisers. • ***Settlement problems***: inhabitants are unhappy because the pipeline will pass through the new area of their settlement. The settlement is relatively wealth although there has been a recent decline in the standard of living conditions resulting from the national economic downturn.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Bees*** Disturbance of any stationary hives located within 300m of the route ***Sensitive vegetation used by bees***	will be erected where a settlement is within 500 m of construction work. **Community liaison meetings held** during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location. **Effectiveness of dust suppression** methods to be	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression

Social Impact Table 30 (Map 30C) (KPs 571.0 – 590.2): Kose Mountains, Sivas/Erzincan Province Border

	Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	and monitoring measures are fully implemented.
	Land Potential complications in expropriation process.	**See Overview of the Land Acquisition Process in Appendix C9**	**See Overview of the Land Acquisition Process in Appendix C9**
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Skills Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials	**Information is highlighted for the Contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints.	**Potential positive benefits** to local settlements.
	Settlement opposed to construction camp. Nearby construction camp would not be welcomed by	Additional consultation to be carried out by the project prior to constructing a camp within 5km.	**Likelihood of significant impacts dependent on distance of settlement from camp.** Impacts arising

Social Impact Table 30 (Map 30C) (KPs 571.0 – 590.2): Kose Mountains, Sivas/Erzincan Province Border

	some/all settlements.	Camp will **not** be located within 5km if against the wishes of the settlement. **Any** interaction between construction workers and communities (eg use of local shop) to be carefully monitored	from breeches of rules and procedures. All incidents to be rapidly resolved and used as examples to reinforce procedures.
	Defining right of way The pipeline route passes through an area that will become residential.	The Project will discuss the routing with settlement authorities to ensure that the RoW will not impede future development of the settlement (eg run beside a road). Additional meeting to be held with the community prior to construction to resolve concerns.	Residual impacts will depend upon routing. If RoW is not well situated, future housing development could put pipeline at risk.
	Negative experience Possible **opposition** to project and **increased sensitivity** to any negative impacts.	BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are	Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Haci Bayram (T)			
• ***Demographics****:* 810 inhabitants. There has been an increase in population over the past five years. 50% of the population migrates. • ***Safety:*** the settlement centre is 1.75km from the pipeline. • ***Project attitude:*** according to the Muhtar, a construction camp would be welcome and there is general awareness about the project. • ***Land ownership & use:*** 60% of land is privately owned by local residents. There is seasonal grazing. There is temporary irrigation. • ***Settlement livelihood:*** agriculture, bee keeping (seven households, for their own consumption) and education are the main sources of livelihood. 90% of inhabitants are farmers. • ***Availability & skills:*** inhabitants have no previous pipeline experience. • ***Accessibility:*** the settlement is accessible all year, the distance from settlement to district centre is 12km. • ***Information provision:*** Literacy rate is 90%. Key sources of information are TVs and radios. • ***Infrastructure*****:** there is a piped, regular supply of water. • ***Settlement problems****:* poor roads, low income and unemployment.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to recruitment*** Decreased access to recruitment process.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No residual impact expected.**

Environmental Impact Table 31 (Maps 31A and 31B) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Cryic or mesic Typic Calcixerolls on soils formed on gently sloping to sloping lands from limestone or marl. • Loamy-skeletal Shallow (or Micro) Xerochrepts on moderately steep and steep lands. • Mesic Calcixerolls on soils occupying gently sloping and sloping lands. • Typic Xerorthents on valley bottoms.	Main potential impacts: • soil erosion; • sediment yield; • soil productivity; • soil contamination; • frost heave; • channel alteration; • waterlogging and compaction.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration.	**MINOR IMPACT** Soil productivity losses are predicted to last less than 3 months after construction is completed. Furthermore, soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
Mesic rolling terrain that, with Sivas Provincial Highway 2 and the gas pipeline, follows the valley of the Kizilirmak River. Elevations lie between 1,600 and 1,800m. Numerous springs emerge near the base of surrounding slopes, and contribute to wet stands in undulating ground adjacent to the Kizilirmak. The sinuous river channel is anastomose, with portions of its flow disappearing in channel sediments rather than flowing over the surface. This slightly degraded landscape of low sensitivity includes a number of small river crossings, each with dense scrub and scattered trees in contrast to the grassy, grazed, gently-rolling valley land beyond. The route will be especially visible here during construction. Arable land is common, irrigated in places along the Kizilirmak valley. Numerous small settlements lie alongside the route. BVS-033 and BVS-0.4 will be located at KP 593.5 and KP 605.6, respectively, both within cultivated land. Approximately 350m^2 of permanent landtake required for each station. A new access road will be	• Visual and soil-related liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel. • Medium to long-term visual impact where the pipeline RoW cuts through thin Calcixerolls to expose the underlying marl, which will persist as a whitish cast across the landscape. • Removal of bushes and trees at small river crossing	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any	**INDIRECT POSITIVE IMPACT** in areas where the BTC and NGP corridors are reinstated. **MINOR TO MODERATE IMPACT** Assuming effective re-instatement, generally short-term minor to moderate impacts, but likely to be highly visible to many people. **MODERATE IMPACTS** where thin marl soils exposed by the Pipeline, persisting as a white

Environmental Impact Table 31 (Maps 31A and 31B) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
constructed to BVS-033of c. 275m in length and to BVS-034 of c. 70m. Cukuryurt settlement lies c. 310m from BVS-034.	trees at small river crossing points will leave some permanent gaps. • Potential for short-term visual impact during construction for villagers in Cukuryurt during construction of BVS-034.	additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply 'Soils' reinstatement specifications above. Particular attention will be paid to the control of dust, noise and traffic during construction at BVS-034.	line across the landscape, visible, however, only during the short-term. **MINOR IMPACT** Given the relatively small size of the block valve station and the temporary nature of construction activities, impacts are anticipated to be minor, subject to implementation of the specified mitigation measures.
Surface Waters			
The pipeline route crosses Aciirmak River and Acisu River. Acisu River is a tributary of the Kizilirmak River and their confluence is c. 1.5km downstream of the BTC Pipeline crossing point.	Disturbance, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Potential for long-term sedimentation and turbidity downstream of the NGP crossing. The NGP lies adjacent and parallel to the river.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to	**INDIRECT POSITIVE IMPACT** where these watercourse crossings previously disturbed during construction of the gas pipeline are reinstated. **MINOR IMPACTS** Although the water quality classifications for both Aciirmak and Acisu Rivers are unknown, only minor impacts

Environmental Impact Table 31 (Maps 31A and 31B) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at these watercourse crossings impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity at the Aciirmak River and Acisu River crossing points, including sediment filters/trapping devices, settling ponds and trench de-watering.	are expected, as disturbance will be limited to the immediate working area. Sedimentation of both watercourses crossed in this section will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
The Imranli Reservoir is currently under construction, lying to the north of the route, and c. 210m away at its closest point. The reservoir will have a volume of 62,500,000m³ at normal surface water elevation and serve an irrigation area of 11,220ha.	The reservoir will receive flows from both Kizilirmak River and Aciirmak River. Potential for indirect disturbance at Imranli Reservoir, resulting in a reduction in water quality.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity at both Kizilirmak River and Aciirmak River crossing points.	**MINOR IMPACT** Sedimentation of Kizilirmak River and Aciirmak River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Noise			
Noise sensitive receptors include: • Koyunkaya settlement (Imranli District, Sivas Province)is located c.	Noise impacts are expected to occur at the following	The following mitigation measures will be applied:	**MAJOR IMPACT** Due to the proximity of the

Environmental Impact Table 31 (Maps 31A and 31B) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
160m from the centreline of the Pipeline; • Pirdede settlement (Imranli District, Sivas Province)is located c. 86m from the centreline of the Pipeline and is located adjacent to a crossing of the NGP; • Cukuryurt settlement is located c. 154m from the centreline of the Pipeline; • Kemerli settlement is located c. 197m from the centreline of the Pipeline.	locations: • Koyunkaya and Cukuryurt settlements during soil stripping, excavations and welding and lowering activities; • Pirdede settlement during soil stripping, welding and lowering, backfilling, excavation works, trenching and bending activities, in addition to sheet piling associated with the crossing of the NGP; • Kemerli settlement during soil stripping activities.	• use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	edge of Pirdede settlement to the Pipeline, short-term noise impacts are expected to occur during soil stripping, welding/lowering and backfilling. Longer-term impacts (ie three to four weeks) are likely to occur during piling activities at the NGP crossing. Stockpiling of spoil, where possible, and mobile noise barriers, will be used to screen nearby dwellings from construction works to the maximum extent possible. However, those nearest may still be exposed to temporary construction noise levels that exceed 70dB(A). It is important to emphasise this is a cautious assessment. The construction programme will make provision for a further assessment based on the true numbers of receptors affected and separation distances of receptors from noise sources and take whatever actions are necessary to reduce impacts to an acceptable level Since Pirdede settlement is located within 100m of piling

Environmental Impact Table 31 (Maps 31A and 31B) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
			activities, vibration impacts are also expected to occur at the nearest properties. **MINOR IMPACTS** Noise impacts are also expected to occur at Koyunkaya and Cukuryurt during soil stripping and welding/lowering activities, and at Kemerli during soil stripping. These impacts will be short-term in nature.
Archaeology and Cultural Heritage			
There are three archaeologically important areas located within the 100m corridor in this section: • Ethnographic Alaouite Cemetery near Koyunkaya settlement is crossed between KPs 591.9 – 591.3 (1st Degree Site*); • Cetelik Tumuli (1st Degree site*) comprises two adjacent tumuli near KP 607.6 and lies within the 100m Corridor; • Kemreli (3rd Degree Site*) – flattened settlement mound within the 100m Corridor, destroyed as a result of construction of the Iran natural gas pipeline and removal of earth for the surrounding marshes. There are ceramic shards dating to Late Calcolithic and Early Bronze Ages on the surface. • Cetelik Settlement (1st Degree site*) * These sites have not yet been registered by the MoC and are provisionally assigned these classifications. Kemreli has been proposed for registration by the regional preservation council	Potential for direct impacts, such as ground disturbance, at all three sites during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of these sites.	The extent of both the ethnographic Alaouite cemetery and Cetelik Tumuli will be investigated during further field surveys prior to construction. This will determine the need for detailed surface research and/or rescue excavations at these sites. Further investigation will delineate both sites and identify a safe route through both sites. The pipeline will be routed to the north of the NGP at the Ethnographic Alaouite Cemetery. Specific mitigation to be developed following site investigations. The pipeline has been re-routed to avoid Kemreli mound.	**MODERATE TO MINOR IMPACTS** Residual impacts cannot be determined precisely for the ethnographic Alaouite cemetery and Cetelik Tumuli at this stage since the extent of these sites are unknown. Archaeological investigations prior to construction will establish the full extent of both sites. However as investigations are expected to find a safe route through these sites, the ultimate scale of impact is likely to be minor. The Alaouite cemetery is expected to be avoided by the route, as further investigations will identify a route to the

Environmental Impact Table 31 (Maps 31A and 31B) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	north of the current BTC alignment and the NGP, away from the site. **MINOR IMPACT** Assuming Kemreli mound is fenced, impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Sivas Socio-Economic Overview

Demographics:
Sivas is the fifth smallest province in terms of population levels (698,000 inhabitants). This is in part due to high out-migration in the 1980s, when a large number of inhabitants migrated from rural areas to district centres, towns or other provinces. The province has the second lowest population density (after Gumushane) with 27 inhabitants per km^2. 50% of inhabitants live in urban areas. Migration has negatively affected agricultural activities, which have been left to the older generations. Approximately 8% of the surveyed population are Alevi Muslims, all others are Sunni Muslims. A very small proportion of respondents speak other languages such as Arabic (0.1%).

Land:
The province is located in the middle of the Anatolian Plateau and has a unique landscape. Circular basins are enclosed by hard gypsum that limits agricultural productivity. Private ownership followed by communal land ownership is most common. Land is relatively evenly distributed amongst surveyed local residents and it is one of the top four pipeline provinces for commercial livestock production (along with Erzincan, Adana and Kayseri). According to the SIS, only 7% of land is irrigated, explained by the shortage of feasible waterways or water sources for irrigation in high plateaus.

Livelihoods:
The economy is based on arable agriculture and animal husbandry. The former is the main economic activity, although large herds of animals graze pastureland. Animal husbandry is carried out by herdsmen who receive annual payments from local residents. This is in part due to the high out-migration of educated young adults for employment elsewhere. The province is ranked seventh (of the ten surveyed provinces) in terms of overall wealth (income and assets).

Infrastructure & Services:
Although water, telephone and electricity infrastructure exist, the supply of water, and to a lesser extent electricity, is irregular. Formal sewerage and waste disposal systems are rare. The average literacy rate is 75% within the surveyed settlements (marginally lower than other pipeline provinces). 38% of respondents had not completed primary school (the highest level found in all surveyed provinces). Almost half of the respondents have completed primary school and a further 12% secondary school, however only 2% had attended university. Most settlements have their own primary schools, or alternatively, the local government transports children from several settlements for education. There is a general lack of health facilities.

Key Problems:
Low-income levels were cited as the top problem for local residents in Sivas. Local residents have also been affected by rising agricultural input prices and limited irrigation infrastructure and are keen to receive agricultural and animal husbandry credit / support from the State.

Project Attitude:
Located on the NGP route, local residents have experienced material losses during construction and are concerned about the unresponsive behaviour of local authorities in dealing with land disputes.

Source: Household and Settlement Survey (2001)

Social Impact Table 31 (Maps 31C) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

MAP 31: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There are two block valve stations.

MAP 31: MAP HIGHLIGHTS

- Three rivers bisect the pipeline, leading to Imranli Dam.
- National highway runs along path of pipeline.
- Predominant land use is rain-fed agriculture. The pipeline also passes through pasture areas.
- Four archaeologically important areas: Ethnographic Alaouite cemetery, Karatepe Mound, two adjacent tumuli and Celetiktepe settlement.

MAP 31: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** at least 11 settlements on this map will be directly impacted by the pipeline project. Six will have land (L) intersected by the proposed pipeline (Koyunkaya, Kevenli, Kemerli, Piredede, Cukuryurt and Durucin), four (Koyunkaya, Toklucak, Uyanik and Cukuryurt) are within 2km of the block valve stations (B), and six (Cukuryurt, Durucin, Imranli, Kemerli, Koyunkaya, Kevenli and Piredede) are within 500m of the pipeline route (D). None are within 5km of a construction camp or pump station. Settlements impacted by traffic have not yet been identified. No settlements are downstream of a river/ creek crossing.

- ***Surveyed:*** two settlements (Gokdere and Piredede) were surveyed (S) and six were interviewed via telephone (T).
- ***Non-surveyed:*** Toklucak (1.1km from the pipeline), Karli (2.25km from the pipeline), Celetiktepe (50m from the pipeline)
- ***Disclosure Meeting Location:*** Koyunkaya

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Uyanik (B)			
• ***Demographics****:* the settlement consists of 100 households with 300 inhabitants. • ***Safety****:* the settlement is situated 1.95km from the pipeline. • ***Project attitude:*** inhabitants are highly positive towards the project. • ***Land ownership & use:*** 88% of land is privately owned by the inhabitants, 10% of land is subject to sharecropping. A diverse variety of crops are cultivated, honey is produced and irrigation also occurs. Grazing takes place in Spring, Summer, October and November. • ***Settlement livelihood:*** livelihood activities include agriculture, bee keeping, construction and transportation. • ***Availability & skills:*** skills available in the settlement include heavy machine operators, heavy vehicle drivers, food service, mechanics	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Skills & resources*** Increased opportunity to provide skilled or semi-	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Information is highlighted to Contractor** so that they can ensure that directly	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Potential positive benefits** to local settlements.

Social Impact Table 31 (Maps 31C) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

machine operators, heavy vehicle drivers, food service, mechanics, tree fellers, drivers, security personnel and welders. 46% of inhabitants would accept temporary employment. • ***Accessibility:*** the settlement is 17km from the district centre of Imranli. The gravel road is of poor quality, however the settlement is accessible all year round. • ***Information provision:*** 90% of the population is literate. The most effective information provision techniques are television and newspapers. • ***Environmental & cultural sites:*** religious buildings are located in this area. • ***Infrastructure:*** piped water is supplied to households year round, there is no alternative water source. There is an electricity supply, but no sewerage or waste disposal system. • ***Services:*** there is a primary school, and whilst there is no health centre, inhabitants have access to a travelling midwife. Sports facilities are also available. • ***Settlement problems:*** problems in this settlement include transport difficulties and low incomes.	skilled labour or to source goods or materials. ***Block Valve Station*** See Environmental Impact Tables and the Overview of Land Acquisition Process in Appendix C9.	impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints.	
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Kevenli (L) (T) (S)			
• ***Demographics****:* there are 58 inhabitants within this settlement. 25% of the population seasonally migrates. • ***Safety****:* the settlement is situated 1km from the pipeline. • ***Project attitude:*** according to the Muhtar*,* the attitude of the inhabitants towards the project is generally positive. • ***Land ownership & use:*** the inhabitants privately own 50% of the land. The other 50% is communally owned land. Irrigation also occurs. • ***Settlement livelihood:*** agriculture, bee keeping (three households produce honey as their only source of income), construction, and local government are the sources of livelihood for the inhabitants of	***Bees*** Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be

Social Impact Table 31 (Maps 31C) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

this settlement. • ***Accessibility:*** it is 16km to the district centre of Imranli. Accessibility is poor from December to February. • ***Information provision:*** 99% of the population is literate. The best information provision tools are television and newspapers. • ***Environmental & cultural sites:*** there is a nearby plateau of environmental significance. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. • ***Settlement problems:*** problems within this settlement include unemployment, low incomes and inadequate childcare.		close to their original location.	facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Accessibility of recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy	**No residual impact expected.**
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Land Potential complications in expropriation process.	**See Overview of Land Acquisition Process in Appendix C9.**	**See Overview of Land Acquisition Process in Appendix C9.**
	Irrigation Loss of flow from planned/	Contractor will **consult** with authorities to determine	**If irrigation water is disrupted** longer than time

	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected.**
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility to information Sectors of the population	**Communication with settlement** must take into account settlement	**Any change can highlight and exacerbate existing divisions** in communities.

Social Impact Table 31 (Maps 31C) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

	may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	characteristics to ensure equal access to information for all residents. This should include: • Using appropriate channels of communication and media. • Emphasising oral communication where literacy is low.	Mitigation measures will keep this to a minimum.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Cukuryurt (L) (D) (B) (T)			
• ***Demographics****:* the settlement comprises 200 inhabitants, 65% of whom migrate seasonally. • ***Safety****:* the settlement is situated 154m from the pipeline. • ***Project attitude:*** attitudes are mixed as the inhabitants believe their land will be damaged, yet feel that the pipeline will benefit the region. • ***Land ownership & use:*** 70% of land is privately owned by inhabitants. No grazing or irrigation occurs. • ***Settlement livelihood:*** agriculture, bee keeping (20 households produce honey, as one of a number of income sources), hunting, manufacturing, trade and local government are the sources of livelihood for inhabitants of this settlement. • ***Accessibility:*** it is 7km to Imranli district centre. The settlement is accessible all year. • ***Information provision:*** 90% of the population is literate. The best information provision tools are television and family. • ***Environmental & cultural sites:*** Yes – around barrage • ***Infrastructure:*** piped water is available to households, however supply is irregular with frequent cuts in water supply. A fountain within the settlement provides an alternative source of water. • ***Settlement problems:*** infrastructure and inadequate access to water	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.**

Social Impact Table 31 (Maps 31C) (KPs 590.2 – 611.6): Imranli Karstic Area, Sivas Province

cause problems for this settlement.	***Bees*** Disturbance of any stationary hives located within 300m of the route	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Hunting Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of	**Significance cannot be established at this time.**

		compensation will be facilitated by the Projects complaints procedure.	
	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport need to be **taken into account** in the recruitment strategy.	**No residual impact expected.**
		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
	Fishing Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.

Environmental Impact Table 32 (Maps 32A and 32B) (KPs 611.6 – 632.0): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Calcixerolls on soils occupying gently sloping and sloping lands. • Loamy-skeletal shallow (or Micro) Xerochrepts on moderately steep and steep lands. • Typic Xerorthents on valley bottoms. • Mesic Clayey-skeletal Micro Xerochrepts on upper slopes and steep lands. • Mesic Gypsic Calcixerolls or loamy Xerochrepts on lower slopes. • Mesic Xerorthents on valley bottoms.	Main potential impacts include: • soil erosion; • soil productivity; • sediment yield; • channel alteration. Other potential impacts include waterlogging and compaction.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Employ equipment mats.	**MODERATE IMPACT** Soil erosion predicted to be visibly active but no rill and gully formation evident. Furthermore, soil productivity losses are predicted to last generally less than one year after construction, but more than three months for arable land and more than 6 months in grazing pasture), but up to 2 years in upland areas with no formal land use.
Landscape and Visual			
West of Imranli, the route climbs into a markedly different landscape – that of polygonal gypseous karst. This complex, hilly terrain gets its name from narrow ridges of crystalline gypsum that totally enclose small basins of gypsic soils which, when seen from the air, resemble a honeycomb. On the ground, the landscape is one of many stony hummocks in a rolling grassy plain. Surface drainage is absent here since the drainage is internal, especially through sinkholes and subterranean passages. Small-scale cereal production and beekeeping occurs in some of the larger internal basins, where their access comes from agricultural tracks. The route descends steeply to cross the meandering Acioz River, its valley forming a green ribbon of meadows and trees in an otherwise more barren landscape, but here as elsewhere, the poorly reinstated NGP forms a massive scar through the landscape, visible from satellite. Associated quarries and tracks disfigure nearby hills and plains. The route continues across a broad generally flat karst plain, lacking trees and surface	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. This may be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. Visual liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any	**INDIRECT POSITIVE IMPACT** in the Acoiz valley where the BTC and NGP corridors are reinstated. **MODERATE IMPACT** Where reinstatement is unlikely to be fully effective in areas where the corridor overlies thin marl soils, it will retain its whitish colour and show as a white line across the landscape, although only in the short-term.

Environmental Impact Table 32 (Maps 32A and 32B) (KPs 611.6 – 632.0): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
drainage, largely cultivated for non-intensive cereal production, and with wide vistas of distant mountains. While the landscape is seriously degraded, its setting is still preserved by surrounding high quality scenery, especially from viewpoints over the Acioz River.		additional mitigation measures to ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply 'Soils' reinstatement specifications above.	
Surface Waters			
The pipeline route crosses Acioz River at KP 625.1. River channel is sinuous with a trapezoidal cross-section. Width of crossing is 27m and the bank-full width is approximately 4m, with an estimated floodplain width of also 27m. Bed consists of sand and gravel and the flow is intermittent and of a uniform and tranquil type. Bank-side vegetation comprises grass and trees, although the riparian vegetation has been disturbed. Water quality samples taken at the crossing point indicate that this is a Class IV river. Adamfaka settlement lies c. 1km downstream of BTC Pipeline crossing point. BVS-035 will be located at KP 625.0 and c. 45m from Acioz River. Approximately 350m2 of permanent landtake required. A new access road will be constructed to the site of c. 40m in length.	Direct disturbance to bank and bed morphology through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in already poor water quality. Potential for long-term sedimentation and turbidity downstream of the NGP crossing. Potential impacts on downstream ecology and water abstraction for human use.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to	**INDIRECT POSITIVE IMPACT** where the Acioz River crossing previously disturbed during construction of the NGP is reinstated. **MINOR IMPACTS** only expected during both pipeline and BVS construction, as disturbance will be limited to the immediate working area. Sedimentation of Acioz River crossed in this section will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 32 (Maps 32A and 32B) (KPs 611.6 – 632.0): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		ensure the integrity of the BTC corridor at this watercourse crossing impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities, such as Adamfaki settlement, and provide where necessary if sedimentation and turbidity persist for more than 3 days at the community.	
Ecology			
Important Ecological Factors European Pond Turtle (globally-threatened) was recorded at the Acioz River. The protection status for this species is given in Table 5.21, Section 5. Acioz River supports fish species of medium commercial value – nose carp (*Chondrostoma regium*), breeding from March to May, transcaucasian barb	Temporary localised disturbance to globally-threatened reptile species between May and September inclusive. The European Pond Turtle typically mates in May,	In advance of construction works associated with the Acoiz River crossing, riverside vegetation will be cleared between beginning of October and end of April, ie outside of the breeding season for	**MINOR IMPACTS** only to globally-threatened amphibians, if the construction period avoids the seasonal sensitivity.

Environmental Impact Table 32 (Maps 32A and 32B) (KPs 611.6 – 632.0): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
(*Capoeta capoeta angorae*), breeding between May and June, and chub (*Leuciscus cephalus*), breeding from April to June.	with eggs (up to 10 per clutch) laid amongst the roots of waterside vegetation in June. Incubation period is dependent upon variable by temperature, but is generally in the order of 70 days. Hatchlings emerge August – September. Temporary disturbance to commercially important fish and aquatic plants providing breeding sites for these species during construction across the Acoiz River.	the European Pond Turtle. For construction activity to be permitted during the breeding season of fish species with medium commercial value, the Contractor will be required to submit specific mitigation measures to avoid impacting breeding fish to BOTAŞ for approval. Such measures will include, but not be limited to, the following: preconstruction survey results indicating that spawning grounds are avoided, the provision of fish passages, etc, in addition to the generic mitigation measures that are required at all river crossings.	**MINOR IMPACTS** at most for all fish species if construction takes place outside of the breeding seasons (ie March to June inclusive). At other times of year (varying by species), impacts will generally be **MINOR** on the basis of the rigid application of water crossing mitigation measures.
Noise			
Noise sensitive receptors include: • Kilickoy settlement in Imranli District located c. 130m from the centreline of the Pipeline; • Yukari Adamfaki settlement located c. 205m from the Pipeline.	Short-term noise impacts are expected to occur at: • Kilickoy settlement during soil stripping, welding and lowering and backfilling activities; • Yukari Adamfaki settlement during soil stripping activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings;	**MINOR IMPACT** Short-term noise impacts are expected to occur at Kilickoy during soil stripping and welding/lowering activities and at Yukari Adamfacki during soil stripping. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. This will be short-term in

Environmental Impact Table 32 (Maps 32A and 32B) (KPs 611.6 – 632.0): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	nature, lasting only for a few days.
Archaeology and Cultural Heritage			
An archaeologically important site, South-West of Kilickoy Settlement, is crossed by the route east of KP 620. This area yields many late Byzantine and Medieval pottery shards, although no architectural remains are visible. The MoC has not yet registered this site. Area to the SW of Kilickoy village has been proposed for registration by the regional preservation council Kalatepe mound (Adamfaki village) – (1st Degree site)	Potential for the site to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of this site.	The extent of the site south-west of Kilickoy Settlement will be investigated during further field surveys prior to construction. This will determine the need for detailed surface research and/or rescue excavations at this site. Further investigation will delineate this site and identify a safe route through. Specific mitigation to be developed following site investigations. The MoC classification for the site will be determined from investigations. Construction will be carried out under the supervision of an	**MODERATE TO MINOR IMPACTS** Residual impacts cannot be determined precisely for this site at this stage since the extent is unknown. Archaeological investigations prior to construction will establish the full extent of the site. However as investigations are expected to find a safe route through these sites, the ultimate scale of impact is likely to be minor and short-term in duration.

Environmental Impact Table 32 (Maps 32A and 32B) (KPs 611.6 – 632.0): Imranli Karstic Area, Sivas Province

		archaeologist authorised by BOTAŞ.	

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

MAP 32: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There is one block valve station.

MAP 32: MAP HIGHLIGHTS

- Unclassified roads link local settlements.
- One river bisects pipeline.
- An archaeologically important site is located south-west of Kilickoy Settlement which yields Byzantine & Medieval pottery. Kalatepe Mound north-west of the pipeline route.
- Main land uses are pasture and rain fed agriculture.

MAP 32: SURVEYED AND IMPACTED SETTLEMENTS

- ***Impacted:*** nine settlements will be directly impacted by the project. Eight settlements will have land intersected by the proposed pipeline (L) (Yaylacik, Derekoy, Begendik, Kilinckoy, Valituncel Mah, Karisyaka Mah, Adamfaki and Nasir). Five settlements (Becek, Kilinckoy, Yaylacik, Derekoy and Adamfaki) are within 500m of the pipeline route (D). None are within 5km of a construction camp or pump station. Two (Adamfaki and Yukari Adamfaki) are within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. One settlement, Adamfaki is 800m downstream of a river crossing (Acioz River).
- ***Surveyed:*** one settlement (Nasir) was surveyed in the field (S) and seven settlements surveyed by telephone (T).
- ***Not surveyed:*** Dogancal (1.8km from the pipeline), Becek (400m from the pipeline), Kabaktepeler (1.5km from the pipeline), Acioz have not been surveyed.
- ***Not on map:*** Valituncel Mah, Karsiyaka Mah and Acioz
- ***Disclosure Meeting Location:*** Nasir

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Yaylacik (L) (D) (T)			
• ***Demographics:*** there are 35 inhabitants in the settlement. • ***Safety:*** the settlement is situated 450m from the pipeline. • ***Pipeline attitude:*** According to the Muhtar, the inhabitants are generally positive about the project. • ***Land ownership & use:*** 99% of the land is privately owned by the inhabitants. No grazing or irrigation is undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (one household produces honey as one of a number of income sources) and local government are the main sources of livelihood. • ***Availability & skills:*** the inhabitants have previous experience of the Iran-Ankara natural gas project.	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Kilinckoy (L) (D) (T)			
• ***Population****:* there are 640 inhabitants, with seasonal migration of 56%. • ***Safety****:* the settlement is situated 130m from the pipeline.	***Construction hazards: human*** Working areas pose safety hazard to residents,	**Road safety training** will be held in schools prior to construction commencing.	**Continued attention** to mitigation measures will be critical to prevent injury.

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

• ***Project attitude:*** inhabitants are concerned about the impact of construction on lands as the natural gas pipeline caused considerable damage. • ***Land ownership & use:*** 80% of land is privately owned by inhabitants. There is no seasonal grazing of settlement livestock and no irrigation. • ***Settlement livelihood:*** sources of livelihood include animal husbandry, bee keeping (one household produces honey as one of a number of income sources) and local government. • ***Accessibility:*** it is 10km to Imranli district centre, accessibility is poor from December to February. • ***Information provision:*** 80% of the population is literate. The most effective information provision tools include television, the telephone and family. • ***Environmental & cultural sites:*** an ancient city, tower and registered stones are of cultural significance. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular and regular water cuts occur. A stored water supply forms an alternative water source. • ***Settlement problems:*** inadequate access to water, unemployment and poor roads are the main problems in this settlement.	particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Bees*** Disturbance of any stationary hives located within 300m of the route.	**Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original	**Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

		position for 15-20 days prior to moving back close to their original location.	facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Fishing Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing. ***Special site*** Refer to Environmental Impact Tables.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected.**
	Negative experience Possible **opposition** to project and **increased sensitivity** to any negative impacts.	BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings.**	Level of residual impact will depend on degree to which concerns are resolved prior to construction.

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Nasir (L) **(S)**			
• ***Demographics:*** there are 400 inhabitants within 60 households. The population is growing due to returning migrants. • ***Safety:*** the settlement is situated 1.17km from the pipeline. • ***Health:*** the sewerage system is poor, leading to health implications. • ***Project attitude:*** inhabitants are generally positive towards the project, as local residents believe that the pipeline will contribute to the development of Turkey. However, they are concerned that the pipeline may harm agricultural fields and pastures. Inhabitants were not satisfied with expropriation payments made during the construction of the natural gas pipeline. Damage to land was not reinstated those landowners that share land have not received payment. Specifically, 45% of the inhabitants believe the pipeline will bring no benefits. 18% believe it will bring employment opportunities to the settlement and 22% believe it will damage social harmony. • ***Land ownership & use:*** 40% of land is owned privately by the inhabitants and 50% is communal forest land holdings. Land owners do not possess title deeds (only right of possession) for their lands. Irrigation activities and seasonal grazing are undertaken. • ***Settlement livelihood:*** animal husbandry (cattle & poultry) is a major income resource. In addition, agriculture (sugar beet, grain and fruit trees) and transport also provide income sources. Crops and animals are also sold at the local bazaar. • ***Availability & skills:*** food service, heavy vehicle drivers, tree fellers, drivers, security and welders are available. 36% of respondents would accept temporary employment on the project. • ***Accessibility:*** it is 18km to Zara, the district centre. The settlement is accessible year round. • ***Information provision:*** 80% of the population is literate. • ***Infrastructure:*** piped water is supplied to households, however, supply is irregular with frequent water cuts and there is no alternative water source. There is an electricity supply but no sewerage or waste disposal system.	***Land*** Potential complications in expropriation process. ***Forest*** Loss of a resource used by settlements. Increased expenditure on other fuel sources. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that	**See Overview of Land Acquisition Process in Appendix C9.** If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Community liaison meetings** held during and	**See Overview of Land Acquisition Process in Appendix C9.** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement. **Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage**

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

sewerage or waste disposal system. • ***Services:*** there is a primary school with one teacher and a health care centre with a midwife. • ***Settlement problems:*** problems include unemployment, a poor sewerage system and inefficient water supply. • ***Other:*** Nasir River passes through the settlement.	compensated for may be affected if mitigation measures not fully implemented ***Skills and resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Negative experience*** Possible **opposition** to project and **increased sensitivity** to any negative impacts.	immediately following construction will identify any additional land that has been affected. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints. BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings.**	**will be compensated for.** **Potential positive benefits** to local settlements. Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

Environmental Impact Table 33 (Maps 33A and 33B) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Calcixerolls on soils occupying gently sloping and sloping lands. • Loamy-skeletal Shallow (or Micro) Xerochrepts on moderately steep and steep lands. • Typic Xerorthents on some valley bottoms.	Main potential impacts: • soil erosion; • sediment yield; • soil productivity; • contaminated soils;	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	**MODERATE IMPACT** Soil erosion predicted to be visibly active but no rill and gully formation evident. Furthermore, soil productivity losses are predicted to last generally less than one year after construction, but more than three months for arable land and more than 6 months in grazing pasture), but up to 2 years in upland areas with no formal land use.
Landscape and Visual			
The route continues across a broad generally flat or lightly undulating, karst plain lacking trees and surface drainage, largely cultivated for non-intensive cereal production, and with wide vistas of distant mountains determining the landscape's huge scale. Shallow soils overlying gypseous marl support limited grazing with small fields of rainfed cereals occupying some valley bottoms. Riparian vegetation marks the path of small tributaries to the Acisu north of the pipeline and the Kirikli south of it. Low-density grasses grow on slopes. High groundwater may occur in some swales. The relatively featureless terrain, its mostly agricultural use and, in particular, the landscape degradation from the parallel NGP, detracts from the landscape quality and renders its low sensitivity. However its exposure and sensitive soils make it highly susceptible to change.	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. This may be long-term or permanent where difficult to reinstate, or where ecological considerations prevent application of fertiliser. Visual liabilities of the NGP, which was not reinstated, potentially accrue to the BTC Pipeline where their RoWs lie adjacent or closely parallel.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC	**INDIRECT POSITIVE IMPACT** in areas where the BTC and NGP and corridors are reinstated. **MODERATE IMPACT** in the short-term where the corridor overlies thin marl soils, as these are unlikely to reinstate to a high standard. Exposed marl may retain its whitish colour and show as a white line across the landscape. However, existing landscape degradation limits extent of

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

Construction Camp B will be tentatively located at KP 640.7, although the precise location for this camp is still being finalised. The camp will occupy an area of c. 14.12ha.	Short-term visual impact on non-marl portions of the route as a result of both pipeline construction and the presence temporary of Construction Camp B during the construction period.	Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at this watercourse crossing impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply 'Soils' reinstatement specifications above. Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as coir fibre.	impact and presents opportunities for improvement.
Surface Waters			
The route crosses three rivers in this section – Nasir River (near KP 631.4); Kamislibogaz River (near KP 635.4); and Acisu River (KPs 635.6 – 636.2). Nasir and Kamislibogaz Rivers are tributaries of the Acisu River, joining c. 1.5km and 1km downstream of crossing point respectively.	Disturbance, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Potential for long-term sedimentation and turbidity downstream of the NGP crossing.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any	**INDIRECT POSITIVE IMPACT** where these watercourse crossings previously disturbed during construction of the NGP is reinstated. **MINOR IMPACTS** Although the water quality classifications for the three watercourses are unknown, only minor impacts are expected, as disturbance will be limited to the immediate working area. Sedimentation of all watercourses crossed in

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

		additional mitigation measures to ensure the integrity of the BTC corridor at these watercourse crossings impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity at these crossing points, including sediment filters/trapping devices, settling ponds and trench de-watering.	this section will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Ecology			
Important Ecological Factors ESA 27 is identified between KP 645.1 and KP 654.2 for four globally-threatened plant species (*Isatis sivasica, Minuartia anatolica var. scleranthoides, Onobrychis stenostachya sp. krausei* and *Lepidium caespitosum*) and one nationally-threatened species (*Tchihatchewia isatidea*). The IUCN status for these species are given in Table 5.20, Section 5. At the Nasir River crossing (KP 632.2), 1 Wryneck (nationally-threatened) was recorded. The protection status for this species is given in Table 5.21, Section 5.	Habitat destruction of plain steppe and habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 27. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

	sensitive for late and second broods.	described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly. • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during reinstatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 27. Preconstruction survey will establish the presence of mature trees, (in particular dead trees, which are the favoured nesting sites of the Wryneck), along the RoW of the pipeline route. If present, these will be removed outside the breeding season.	schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.
Noise			
Sucak settlement in Zara District is located c. 160m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Sucak during soil stripping activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed	**MINOR IMPACT** Short-term noise impacts are expected to occur during soil stripping. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature,

Social Impact Table 32 (Map 32C) (KPs 661.6 – 632.0): Imranli Karstic Area, Sivas Province

		with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings and where possible, utilising existing screening, including that arising from the stockpiling of materials. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	lasting only for a few days.
Archaeology and Cultural Heritage			
The flat settlement of Sucak (3rd Degree Site*) lies within the 100m Corridor. Although no architectural remains were found on this site, ceramic shards dating to the Roman period were discovered. * This site has not yet been registered by the MoC and is provisionally assigned this classification. Sucak settlement has been proposed for registration by the regional preservation council	Potential for site to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	The Pipeline has been re-routed to avoid this site. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

MAP 33: PROJECT INFORMATION

A primary construction camp (Lot B) will be located in the area. It will require 14.12ha. It is located mostly on state land, and also on two smaller private land parcels. (Originally this construction camp was located 2.4km to the west. It was relocated away from an important bird site, and away from an area that was largely privately owned. Changing the location of the site has minimised resultant impacts). There is no pump station and no block valve station in the area.

MAP 33: MAP HIGHLIGHTS

- Three rivers and one access road bisect the pipeline.
- Main land use is rain-fed agriculture and pasture, with a small amount of irrigated agriculture near water courses.
- The pipeline route passes north of the archaeological site 'Nasir Settlement Surroundings', a hillside settlement.
- Seasonal migration occurs in all settlements.
- Hunting occurs at two settlements.
- There is insufficient water in many settlements.
- Agriculture and animal husbandry are undertaken.

MAP 33: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** 15 settlements on this map will be directly impacted by the pipeline project. Five (Demiryurt, Derbent, Ekinli, Tekkekoy and Sucak) will have land intersected by the proposed pipeline (L). One (Sucak) is within 500m of the pipeline route (D); three are within 2km of a construction camp (C) (Tekkekoy, Kadriye, Ciftlik); and eight are within 5km of a construction camp (Osmaniye, Kumbet, Baglama, Ucoluk, Akdegirmen, Ungar, Yarimkaya, Kevenli). Settlements impacted by traffic have not yet been identified.

- ***Surveyed****:* five settlements were surveyed by telephone (T).
- ***Not surveyed:*** Muhmutaga Farm (1.8km from the pipeline).
- ***Not on map:*** Ucoluk, Akdegirmen, Ungar, Yarimkaya
- ***Disclosure Meeting Location:*** Tekkekoy

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Sucak (L) (D) (T)

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

positive towards the project. • ***Land ownership & use:*** 70% of land is privately owned by inhabitants. Seasonal grazing and irrigation occur. • ***Settlement livelihood:*** agriculture, bee keeping (six households produce honey as one of a number of income sources), hunting, manufacturing, construction and local government are all sources of livelihood for the settlement. • ***Availability & skills:*** inhabitants have previous experience of the Iran-Ankara natural gas project. • ***Accessibility:*** the settlement is 12km from the district centre of Zara and the settlement is accessible all year. • ***Information provision:*** 90% of the population is literate. The best information provision tools include television, radio and the newspaper. • ***Infrastructure:*** a regular supply of piped water is supplied to households. • ***Settlement problems:*** unemployment, low income and poor roads are amongst the problems faced by the settlement.		**meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work.	**Benefits** from health and safety awareness raising.
	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage will be compensated for.**
	Construction hazards: animals Trench poses safety hazard for livestock.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Hunting Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed.	**Significance cannot be established at this time.**
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Availability of information Sectors of the population may not have access to	**Communication with settlement** must take into	**Any change can highlight and exacerbate existing**

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

	project related information on employment opportunities, potential disruption to utilities, etc. ***Skills and resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Accessibility to recruitment*** Decreased access to recruitment process.	account settlement characteristics to ensure equal access to information for all residents. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**divisions** in communities. Mitigation measures will keep this to a minimum. **Potential positive benefits** to local settlements. **No residual impact expected.**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Tekkekoy (L) (C) (T)			
• ***Demographics:*** there are 395 inhabitants with seasonal migration of 77% (agriculture 60%, students 12%, seasonal workers 5%). • ***Safety:*** the settlement is situated 3.2km from the pipeline and the nearest house is 3km from the pipeline. The distance from the construction camp to the nearest house is 3-4km. • ***Project attitude:*** attitudes towards the project are generally positive. The construction camp is generally welcome (one inhabitant is against it). Perceived benefits of the construction camp include the potential for the local road quality to be upgraded, and the potential to sell dairy and meat products to the camp. The settlement also has	***Construction Camp*** Primary receptor of impacts resulting from construction workers.	**Monthly community liaison** meetings will be held. **Preferential employment** opportunities. **Project to liase** with local health authorities. BTC Company to look at opportunities to cooperate in	**Low likelihood of significant impacts.** Potential for impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures.

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

sell dairy and meat products to the camp. The settlement also has two trucks and 25 tractors that could be used. There are expectations of possible employment opportunities at the construction camp and in the construction of the pipeline, increased settlement income and the potential to offer transportation services to the camp. • ***Availability & skills:*** inhabitants have experience from the natural gas pipeline, which passes to the south-east of the settlement. • ***Land ownership at construction site:*** the campsite is 14.12ha in size, most of which is state land. It also encompasses two smaller private land parcels that are owned by Tekke local residents with legal title. • ***Land ownership & use:*** 98% of the land is privately owned by inhabitants. Seasonal grazing occurs on pasture land or private land from May to October. For the last five years there has been no irrigation due to damage to the water supply system. The land ownership at the camp site is mostly state land consisting of two private lands. • ***Settlement livelihood:*** animal husbandry, in particular cattle, is the main economic activity undertaken in the settlement with significant dairy and meat production. Inhabitants claim that they could provide such products to the construction camp. A secondary economic activity is agriculture – grain: wheat & barley (produced and sold by households), sugar beet (sold), wood (sold), animal feed (used), vegetables (subsistence). In addition, bee keeping (three households produce honey as one of a number of income sources), trade, seasonal construction and local government activities are undertaken. 10% of inhabitants are unemployed. Women undertake agricultural work for the family. • ***Accessibility:*** although the road is of poor quality, the settlement is accessible most of the year due to its proximity to Zara, the district centre. However, the settlement is inaccessible for a short period during the winter months. • ***Information provision:*** 75% of the population is literate, although only 50% of women are literate. The best information provision tools include television, newspapers, radio, family and the imam	***Land*** Temporary expropriation of 14.12ha for the construction camp. ***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to	providing **health awareness training.** **See Overview of Land Acquisition Process in Appendix C9.** **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should	**Low likelihood of significant health impacts**. **Benefits** from raising health awareness of workforce (many of whom are local). Further positive benefits dependent on scale of social investment activities. **See Overview of Land Acquisition Process in Appendix C9.** **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

include television, newspapers, radio, family and the imam. • ***Environmental & cultural sites:*** there is an old bridge to the north of the settlement; Seyhmerzuban mausoleum is next to the cemetery north of the settlement and a cave which can be traced back to the Stone Age is located west of the settlement. • ***Infrastructure:*** piped water supplies households, however supply is irregular with frequent water cuts. An alternative water source is to carry water to the settlement from nearby springs. Drinking water is supplied by the same system serving Zara district centre. There is a good electricity supply but no sewerage or adequate waste disposal systems. • ***Services:*** almost every household has a telephone and the settlement receives mobile phone coverage. There is a five year primary school and students travel to Zara district centre for a further three years of education. There is regular public transport to Zara district centre. There is no ATM, coffee house, market or library. • ***Settlement problems:*** low income, infrastructure problems, unemployment, poor road and insufficient water supply for irrigation are amongst the problems facing this settlement.	utilities, etc. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility of recruitment*** Decreased access to recruitment process ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	include emphasising oral communication where literacy is low. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No residual impact expected.** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Kadriye (C) **(S)**			
• ***Demographics:*** there are no inhabitants during the winter. The Muhtar*'s* family live in the settlement during the summer. • ***Safety:*** it is 5km from the proposed camp to the nearest house and 1km to the nearest land plot. • ***Project attitude:*** inhabitants are generally positive towards the project. Attitudes towards the construction camp are welcoming. • ***Land ownership & use:*** Tekke inhabitants own the land that the proposed construction camp would be situated on. Seasonal irrigation and grazing are undertaken.	***Construction camp Impacts:*** Primary receptors of impacts resulting from construction workers.	**Monthly community liaison** meetings will be held. **Preferential employment** opportunities. **Project to liase** with local health authorities BTC Company to look at	**Low likelihood of significant impacts.** Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures.

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

• ***Settlement livelihood:*** Sources of livelihood include grain – wheat & barley (consuming & selling), animal feed, vegetables (subsistence); bee keeping and animal husbandry – cattle. During summer, local residents are involved in agricultural pursuits, in the winter inhabitants leave the settlement. • ***Accessibility:*** it is 5.3km to the district centre. A new road has been built within the past five years but it is of poor quality. The settlement is not accessible in January or February. • ***Information provision:*** 100% of the population, including women are literate. The best information tools include TV, radio, family, neighbours and the Muhtar. • ***Environmental & cultural sites:*** there is a thermal spring, used for jaundice treatment, 200m north of the settlement. • ***Infrastructure:*** the main source of water is piped water. There is a regular electricity supply but no sewerage system. Waste is recycled. • ***Services:*** there is a telephone in the settlement and there is mobile phone coverage. There is no school. • ***Other settlement services (of potential use to construction workers):*** none		opportunities to cooperate in providing **health awareness training.** Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**Low likelihood of significant health impacts**. **Benefits** from raising health awareness of workforce (many of whom are local). Further positive benefits dependent on scale of social investment activities. **No residual impact expected.** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility of recruitment Decreased access to recruitment process. ***Special site*** See Environmental Impact Tables. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.		
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Kalkan Ciftlik Mah (C) (S)			
• ***Demographics:*** there are 84 inhabitants, 52 women & 32 men. • ***Safety:*** 2.5km from the proposed camp to nearest house.	***Construction Camp Impacts:***	**Monthly community liaison** meetings will be held.	**Low likelihood of significant impacts.**

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

• ***Project attitude:*** attitudes towards the project are generally positive and construction camps would be welcome. Perceived benefits of a construction camp include possible employment opportunities at the camp and in pipeline construction. They anticipate increased income, the potential to sell items such as milk and cheese to the camp, the potential for settlement owned tractors to be utilised during construction and for the local road quality to be improved. There are no perceived problems from the construction camp but local roads are of poor quality and would not be suitable for heavy traffic. The inhabitants do not expect any tensions with construction workers. • ***Land ownership at Construction Camp:*** largely state owned. Also includes two private land parcels owned by Tekke local residents with legal title. • ***Land ownership & use:*** the land is privately owned and legal titles are held. Grazing occurs on pasture land and private land from May to November. There is almost no irrigation due to insufficient water supply. • ***Settlement livelihood:*** sources of livelihood include agriculture – grain (for selling & household consumption), wheat, vegetables (for household consumption), legumes (for selling & household consumption), wood; animal husbandry - bovine, poultry, ovine, cattle, bee-keeping and seasonal construction. Milk and cheese is produced predominantly for subsistence. 12% of the population is unemployed. • ***Accessibility:*** Roads are old and the quality is poor. • ***Information provision:*** Almost all the population is literate, including women. The best local information tools include television, radio, family, neighbours, imam and the school. • ***Environmental & cultural sites:*** there is a small artificial lake very close to the proposed camp area which birds use during their migration season (spring and autumn). Also, foxes and rabbits are present in the region. • ***Availability & skills:*** none of the inhabitants worked on the natural gas pipeline.	Primary receptor of impacts resulting from construction workers. ***Special site*** Refer to Environmental Impact Tables. ***Skills and services*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	**Preferential employment** opportunities. **Project to liase** with local health authorities BTC Company to look at opportunities to cooperate in providing **health awareness training.** **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints. Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures. **Low likelihood of significant health impacts**. **Benefits** from raising health awareness of workforce (many of whom are local). Further positive benefits dependent on scale of social investment activities. **Potential positive benefits** to local settlements. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Social Impact Table 33 (Map 33C) (KPs 632.0 – 651.4): Imranli Karstic Area, Sivas Province

• ***Infrastructure:*** piped water is supplied to households. The electricity supply is irregular in winter and spring due to birds damaging the electricity lines, there is no alternative source of energy. There is no sewerage system so waste is recycled as fertilizer, burned or hidden. • ***Services:*** each household has a telephone; and there is mobile telephone coverage. There is a five year primary school. Students travel to Zara district for a further three years of education. However, the primary school will be closed in 2002 due to a lack of students. There is regular public transport to Zara district centre. There is no ATM, coffee house, market or library. • ***Settlement problems:*** insufficient roads, unemployment, insufficient electricity supply and insufficient water for irrigation are all problems in this settlement.			

Environmental Impact Table 34 (Maps 34A and 34B) (KPs 651.4 – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Calcixerolls on soils occupying gently sloping and sloping lands. • Loamy-skeletal Shallow (or Micro) Xerochrepts on moderately steep and steep lands. • Typic Xerorthents on some valley bottoms. • Typic Rhodoxeralfs on valley bottom soils that have a reddish colour.	Main potential impacts: • soil erosion; • soil productivity. Other potential impacts include: • sediment yield; • channel alteration; • soil contamination; • waterlogging and compaction (rare).	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Employ equipment mats.	**MODERATE IMPACT** Soil erosion predicted to be visibly active but no rill and gully formation evident. Furthermore, soil productivity losses are predicted to last generally less than one year after construction, but more than three months for arable land and more than 6 months in grazing pasture), but up to 2 years in upland areas with no formal land use.
Landscape and Visual			
The route continues across the flat to lightly undulating, exposed karst plain and has been largely cultivated for non-intensive cereal production, presenting wide vistas of distant mountains. It descends to cross the Acisu River, a wide meandering river with stony riffles and deep pools and sandy river cliffs, where it temporarily diverges from the gas pipeline. It continues west through the hilly and more distinctive terrain north of Kuru Lake, before turning south-west at KP 662 across a rolling landscape of marly soils broken by occasional outcrops of anhydrite. Marl dominates the landscape by giving a whitish cast to surrounding hills. Shallow landslides and their debris scar some slopes. The route descends c. 100m to cross the Tatli River at KP 670 before turning westerly across gypseous hills at about 1400m elevation. Occasional streams every 2 – 3km cross the route, the larger of which are marked by riparian vegetation on their banks. Small settlements occupy flat lands near streams. Grasses occupy most slopes, but many are also bare with their underlying gypsum, marl, or limestone exposed as a whitish cast	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. May be long-term or permanent where difficult to reinstate, or where ecological considerations prevent application of fertiliser. Short-term visual impact on non-marl portions of the route. Visual liabilities of the NGP, which was not reinstated, potentially accrue to the BTC Pipeline where their RoWs lie adjacent or closely parallel.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to	**INDIRECT POSITIVE IMPACT** in areas where the BTC and NGP corridors are reinstated. **MODERATE IMPACT** in the short-term where the corridor overlies thin marl soils, as these are unlikely to reinstate to a high standard. Exposed marl may retain its whitish colour and show as a white line across the landscape. However, existing landscape degradation limits extent of impact and presents opportunities for improvement.

Environmental Impact Table 34 (Maps 34A and 34B) (KPs 651.4 – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
on the landscape. Low-density grazing and rainfed cereals support the local economy.		ensure the integrity of the BTC corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as coir fibre.	
Surface Waters			
The pipeline route crosses the Acisu River at KP 660.6. River channel is irregular and meandering, with point and mid-channel bars. Cross-section is parabolic at the meander inflection point; bank cutting at meander apex changes cross-section. Width of crossing is 45m and bank-full width is approximately 20m, although floodplain is between 225 and 450m. Bed consists of sand and gravel and the flow is perennial, of a uniform and tranquil type. Bank-side vegetation comprises shrubs and trees and there is no riparian vegetation. Water samples taken 430m downstream of the crossing point indicate that this is a Class IV river.	Direct disturbance to bank and bed morphology through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in already poor water quality. Potential for short and long-term sedimentation and turbidity. Potential impacts on downstream ecology and water abstraction for human use.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any	**INDIRECT POSITIVE IMPACT** where the Acisu River crossing previously disturbed during construction of the NGP is reinstated. **MINOR IMPACTS** only expected, as disturbance will be limited to the immediate working area. Sedimentation of Acisu River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 34 (Maps 34A and 34B) (KPs 651.4 – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		additional mitigation measures to ensure the integrity of the BTC corridor at this watercourse crossing impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities and provide where necessary if sedimentation and turbidity persist for more than 3 days at a community.	
The route crosses Tatli River between KPs 673.7 – 674.0. River channel form, which was re-constructed during construction of the natural gas pipeline, is irregular and meanders with a parabolic cross-section. Pool and riffle bars present, although mid-channel bars are located upstream of crossing point. Width of crossing is 30m and bank-full width is approximately 5m, although the floodplain is between 30 and 150m wide. Upstream width of the natural channel is approximately 10m wide. Bed consists of sand and gravel and the flow is perennial, of a uniform and	Direct disturbance to bank and bed morphology through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality, which is already highly	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix	**INDIRECT POSITIVE IMPACT** where these watercourse crossings previously disturbed during construction of the NGP is reinstated. **MINOR IMPACTS**

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
tranquil type. Riparian vegetation is fragmentary and disturbed and there is no bank-side vegetation. A bridge is located approximately 1km downstream of the crossing point. Water samples taken 480m downstream of the crossing point indicate that this is a Class IV river. Korkuyu Creek is crossed by the route near KP 670 and is a tributary of the Tatli River. Confluence is c. 3km downstream of crossing point.	polluted in Tatli River. Potential for long-term sedimentation and turbidity downstream of crossing point of both Tatli River and Korkuyu Creek.	C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at these watercourse crossings impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench.	Tatli River is a poor quality river (Class IV) and the classification for Korkuyu Creek is unknown. However, only minor impacts are expected, as disturbance will be limited to the immediate working areas for both watercourses. Sedimentation of Tatli River and Korkuyu Creek will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Ecology			
Protected Areas Kuru Lake is a large, shallow, eutrophic lake, (lying c. 1.25km south of the pipeline route), with extensive reedbeds and marsh. This lake is being considered by the Ministry of Environment (MoE) for designation as an Internationally Important Wetland under the Ramsar Convention. At least seven nationally-threatened bird species have been recorded.	See Potential Impacts below. There will be no impact to the integrity of the lake and therefore its proposed protection status.	See Mitigation Measures below.	See Residual Impacts below.

Environmental Impact Table 34 (Maps 34A and 34B) (KPs 651.4 – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Important Ecological Factors ESA 27 continues for c. 2.8km(see Environmental Impact Table 33 and Map 33B for previous description of species). ESA 28 is identified between KP 659.5 and KP 664.4 for two globally-threatened plant species (*Cousinia sivasica* and *Isatis sivasica*) and one nationally-threatened species (*Tchihatchewia isatidea*). In addition, two globally-threatened plants (*Minuartia anatolica var. lanuginosa* and *Aethionema lepidioides*) occur just outside the 500m Corridor parallel to this ESA. The IUCN status for these species are given in Table 5.20, Section 5. Tracks of Eurasian Otter (globally-threatened) were recorded from the banks of the Acisu River near the pipeline crossing point. The protection status for this species is given in Table 5.21, Section 5. Kuru Lake supports at least seven nationally-threatened birds. Totals on 26.05.2001 include - Red-necked Grebe 14, Greylag Goose 10 plus 3 chicks, Garganey 7, Shoveler 8, Pochard 11, Marsh Harrier 3, and Common Crane 2. The protection status for these species are given in Table 5.21, Section 5. The sandy river banks of Acisu River between KP 660.4 to KP 660.7 are an important area for bird species. 2 Black Stork, 1 Marsh Harrier, and 1 Whinchat (all nationally-threatened) were recorded here, with a large sand martin colony. Furthermore, another Whinchat was recorded at each of KP 667.5 and KP 673.0. The protection status for these species are given in Table 5.21, Section 5. BVS-036 will be located at KP 660.9 on cultivated land within ESA28. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to this site of c. 25m in length.	Destruction of plain steppe and habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Minor temporary disturbances are expected to a globally-threatened mammal during seasonal sensitivities (see EMMP, Appendix C1): • breeding season for the Eurasian Otter is year round in Turkey, with a tendency towards the spring period in cooler regions. While the Kuru Lake is distant enough from the Pipeline for construction not to cause undue disturbance, disturbance could arise if pipe dumps, contractor's yards or camps are located in this area. Disturbance from construction personnel walking or driving around the lake would also be detrimental. Potential for direct disturbance to nationally-threatened birds	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 28. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly. • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during reinstatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 28	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACT** at most to the Eurasian Otter during the construction period where the specified mitigation measures are applied for the seasonal sensitivities identified. **MINOR IMPACTS** at most at Kuru Lake based on avoidance and where the specified mitigation measures are applied. **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. This is particularly critical for the sand martin colony, which occupies the Acisu River banks between March and September, although preconstruction surveys will

Environmental Impact Table 34 (Maps 34A and 34B) (KPs 651.4 – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods. The sand martin colony likely to be occupied from March to September. Permanent loss of 350m2 of habitat during construction of BVS-036 within ESA 28.	sparingly or not at all in ESA 28 despite this being mostly cultivated land. Preconstruction surveys of the RoW in the vicinity of river crossings will aim to identify the location and extent of otter holts within the vicinity (250m) of intended river crossings. If discovered these may be cleared in the late summer months under the close supervision of an ecologist approved by BOTAŞ. Preconstruction survey to establish location of sand martin colony in relation to Acisu River crossing; if within 100m of the centre line of works, construction will be undertaken between October and March. The sand martin colony and areas of reeds and dense vegetation will be placed out of bounds for construction workers. In addition, the clearance of riverside reedbeds and other dense vegetation in advance of the construction of the Acisu River crossing to be undertaken outside the April – July period for the Marsh Harrier.	confirm the presence of this species at the pipeline crossing point of the Acisu River. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April for all bird species except for the sand martin, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACT** Based on the mitigation measures described, the small area of habitat affected and the temporary nature of construction activities, it is predicted that only minor impacts on the biological environment will occur as a result of construction activities at BVS-036. This assessment will be confirmed by the site-specific survey prior to construction.

Environmental Impact Table 34 (Maps 34A and 34B) (KPs 651.4 – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		The presence of the Black Stork between April and July probably indicates that breeding is occurring. If this is confirmed by preconstruction surveys during this period, the location of nest sites within 100m of the RoW will be determined and construction within 500m of the nest site will be avoided between April and July. Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Whinchat (April to July). Prior to construction of BVS-036, a site specific survey will be undertaken by an ecological specialist to identify and locate threatened species at the site and at any surrounding areas potentially affected by construction activities. Based on the findings of this survey, appropriate mitigation will be determined. The area of sensitive habitat in ESA 28 affected by construction activities will be minimised to the minimum necessary for safe working.	
Noise			
Topcu Yenikoy settlement is located c. 161m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Topcu Yenikoy settlement during soil	The following mitigation measures will be applied:	**MINOR IMPACT** Short-term noise impacts are expected to occur during soil

Environmental Impact Table 34 (Maps 34A and 34B) (KPs 651.4 – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	stripping and welding and lowering activities.	• use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	stripping and welding/lowering activities. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.
Archaeology and Cultural Heritage			
(i) Topcuyenikoy Mound - 1st Degree; (ii) Karapinar Mounds - 1st Degree; (iii) Kaletepe - 1st Degree			

|Social Impact Table 34 (Map 34C) (KPs 651. – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

MAP 34: PROJECT INFORMATION			
There are no pump stations or construction camps in the area. There is one block valve station.			
MAP 34: MAP HIGHLIGHTS			
• Two rivers and one creek bisect the pipeline. • Access roads link some settlements. • A potential RAMSAR site (Kuru Lake) is located 1.7km south of pipeline. • Kalatepe Hill is a first degree archaeological site. • Main land uses are pasture and rain fed agriculture.			
MAP 34: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** five settlements will be directly impacted by the pipeline project. Two settlements will have land intersected by the proposed pipeline (Topcuyenikoy, Bakimli); three (Hoplamaz, Kalatepe and Topcu Yenikoy) are within 500m of the pipeline route (D). None are within 5km of a construction camp or pump station. One (Topcyenikoy) is within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. Topcu Yenikoy is downstream of the Acisu River crossing (R). • ***Surveyed:*** two settlements (Bakili and Topcu Yenikoy) were surveyed by telephone (T). • ***Not surveyed:*** Ahmetcavus Mah (1.95km from the pipeline), Desturoglu (1.6km from the pipeline), Hoplamaz (700m from the pipeline), Kalatepe (very close to pipeline, on the Tafli River).			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Topcu Yenikoy (L) (D) (B) (R) (T)			
• ***Demographics:*** 130 inhabitants reside in the settlement, with seasonal migration of 50%. • ***Safety****:* the settlement is situated 400m from the pipeline, the nearest house is 75m from the pipeline. • ***Project attitude:*** attitudes towards the project are mixed and inhabitants are concerned their land will be damaged. • ***Land ownership & use:*** share cropping is the predominant land use (90% of inhabitants). Few inhabitants have legal ownership of land. No animal grazing occurs but irrigation does take place. • ***Settlement livelihood:*** agriculture, bee keeping (3 households produce honey as one of a number of income sources), hunting,	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

|Social Impact Table 34 (Map 34C) (KPs 651. – 675.0): Imranli Karst Area (North of Kuru Lake), Sivas Province

construction and local government provide sources of livelihood. • ***Availability & skills:*** inhabitants have previous experience of the Iran-Ankara natural gas project. • ***Accessibility:*** the settlement is 22km from Hafik district centre. The settlement is accessible all year. • ***Information provision:*** 80% of the population is literate. • ***Infrastructure:*** piped water is supplied to households and a fountain in the settlement provides an alternative water source. • ***Settlement problems:*** problems include inadequate access to water, low incomes and unemployment.		settlement is within 500 m of construction work.	
	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage will be compensated for.**
	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Land Potential complications in	**See Overview of Land Acquisition Process in**	**See Overview of Land Acquisition Process in**

• ***Settlement livelihood:*** agriculture and local government are the main sources of livelihood for the inhabitants of this settlement. • ***Availability & skills:*** inhabitants have previous experience of the Iran-Ankara natural gas project. • ***Accessibility:*** he settlement is 17.5km from the district centre. Accessibility is poor from December to February. • ***Information provision:*** 99% of the population is literate. • ***Environmental & cultural sites:*** a nearby castle is of cultural significance. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular with frequent water cuts. A settlement fountain provides an alternative water supply. • ***Settlement problems:*** infrastructure problems, poor roads and poor irrigation are amongst the problems facing the settlement.		width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	
	Construction hazards: animals Trench poses safety hazard for livestock	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.
	Accessibility to recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport need to be **taken into account** in the recruitment strategy.	**No residual impact expected**
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Environmental Impact Table 35 (Maps 35A and 35B) (KPs 675.0 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Loamy-skeletal Shallow (or Micro) Xerochrepts on moderately steep and steep lands. • Mesic Calcixerolls on lands occupying some valley bottoms and nearby slopes. • Typic Xerorthents on other valley bottoms. • Typic Rhodoxeralfs on valley bottom soils that have a reddish colour.	Main potential impacts: • soil erosion; • soil productivity; • sediment yield; • channel alteration.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	**MODERATE IMPACT** Soil erosion predicted to be visibly active but no rill and gully formation evident. Furthermore, soil productivity losses are predicted to last generally less than one year after construction, but more than three months for arable land and more than 6 months in grazing pasture), but up to 2 years in upland areas with no formal land use.
Landscape and Visual			
The route crosses the Tuzla Creek, another river scarred severely by the NGP. From here to Sivritepe settlement the route crosses the familiar rugged karst land with its rocky outcrops, intermittent degraded steppe grasslands and low grade cereal cultivation. Landscape sensitivity is generally low. Occasional streams every 2 – 3km cross the route, the larger of which are marked by lush riparian vegetation. Small settlements occupy flat lands near the streams. Grasses occupy most slopes, but many are also bare with their underlying gypsum, marl, or limestone exposed as a whitish cast on the landscape. Low-density grazing and rainfed cereals support the local economy. Irrigated farmland occurs near the settlement of Akpinar and by the Karasu River crossing.	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. May be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. Short-term visual impact on non-marl portions of the route. Visual liabilities of the NGP potentially accrue to the BTC Pipeline where their two RoWs lie adjacent or closely parallel.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC	**INDIRECT POSITIVE IMPACT** in areas where the BTC and NGP corridors are reinstated. **MINOR IMPACTS** in the short-term where the corridor overlies thin marl soils, as these are unlikely to reinstate to a high standard. Exposed marl may retain its whitish colour and show as a white line across the landscape. However, the flat landscape with potential upland viewpoints several kilometres away, presents limited viewing opportunity and, with the

Environmental Impact Table 35 (Maps 35A and 35B) (KPs 675.0 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as coir fibre. Extensive reinstatement of riparian scrub will be necessary at the Tuzla Creek crossing.	existing landscape degradation limits the extent of impact to minor.
Surface Waters			
The route crosses Tuzla River between KPs 676 – 678.0). The river channel has been severely damaged by construction of the NGP. BVS-037 will be located at KP 678.0 and c. 90m from Tuzla River. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site, c. 75m in length. Islim River is crossed by the route at KP 690.1.	Disturbance, directly through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Potential for short-term sedimentation and turbidity (if flowing) downstream of the NGP crossing.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to	**INDIRECT POSITIVE IMPACT** where these watercourse crossings previously disturbed during construction of the NGP is reinstated. **MINOR IMPACTS** Although the water quality classifications for the two watercourses are unknown, only minor impacts are expected during both pipeline

Environmental Impact Table 35 (Maps 35A and 35B) (KPs 675.0 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor at these watercourse crossings impacted by the presence and proximity of the NGP. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity at these crossing points, including sediment filters/trapping devices, settling ponds and trench de-watering.	and BVS construction, as disturbance will be limited to the immediate working area. Sedimentation of Tuzla River and Islim River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Ecology			
Important Ecological Factors ESAs 29-32 are identified for the following globally-threatened plant species: • *Alyssum caespitosum* and *Galium cornigerum* within ESA 29 (between KP 679.2 and KP 680.5); • *Minuartia anatolica var. lanuginosa* within ESA 30 (between KP 685.6 and KP 686.2); • *Cousinia sivasica* within ESA 31 (between KP 688.7 and KP 689.2); • *Cousinia sivasica* within ESA 32 (between KP 693.0 and KP 693.4). In addition, one globally-threatened plant (*Minuartia rimarum var. multiflora*) occurs just outside the corridor north of ESA 29. The IUCN status for these	Habitat destruction of plain steppe and habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 29-32. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor at ESA 29. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for

Environmental Impact Table 35 (Maps 35A and 35B) (KPs 675.0 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
occurs just outside the corridor north of ESA 29. The IUCN status for these species are given in Table 5.20, Section 5. At KP 690.9 near the Islim River, 1 Black Stork, 1 Common Crane and 1 Whinchat (all nationally-threatened) were recorded. 1 Whinchat was recorded at both KPs 678.7 and the Islim River crossing (KP 690.1) and 2 at KP 685.1. The protection status for these species are given in Table 5.21, Section 5.	if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during reinstatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESAs 29-32. The presence of the Black Stork between April and July, probably indicates that breeding is occurring. If this is confirmed by preconstruction surveys during this period, the location of nest sites within 100m of the RoW will be determined and construction within 500m of the nest site will be avoided between April and July.	breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Environmental Impact Table 35 (Maps 35A and 35B) (KPs 675.0 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Whinchat (April to July). Clearance of riverside vegetation at Islim River will be avoided between April and July for the Common Crane.	
Noise			
Akpinar settlement in Hafik District is located c. 173m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Akpinar settlement during soil stripping and welding and lowering activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for	**MINOR IMPACT** Short-term noise impacts are expected to occur at Akpinar during soil stripping activities. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.

Environmental Impact Table 35 (Maps 35A and 35B) (KPs 675.0 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	
Archaeology and Cultural Heritage			
Akpinartepe Mound (1st Degree Site*) is located within the 100m Corridor and lies c. 50m from the route at KP 682.0. * This site has not yet been registered by the MoC and is provisionally assigned this classification.	Indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	This site will be fenced throughout the construction period. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Assuming Akpinartepe Mound is fenced, impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Social Impact Table 35 (Map 35C) (KPs 675 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

MAP 35: PROJECT INFORMATION			
There are no pump stations or construction camps in the area. There is a block valve station.			
MAP 35: MAP HIGHLIGHTS			
• Pipeline crosses two rivers and one creek. • Passes by archaeological sites, Yugtepe Mound and Akpinartepe Mound. • Access roads link many of the settlements in the area. • Main land uses are pasture, irrigated agriculture and rain-fed agriculture.			
MAP 35: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** seven settlements on this map will be directly impacted by the pipeline project (Golcuk, Celalli, Alcioren, Akpinar, Karayun, Tahtakement, Yavu). They will all have land intersected by the proposed pipeline (L). One of these (Akpinar) is also within 500m of the pipeline route (D). None are within 5km of a construction camp or pump station. Two (Golcuk and Celalli) are within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. No settlements are downstream of a pipeline river crossing (R). • ***Surveyed:*** two settlements (Celalli, Karayun) were surveyed (S) in the field and five settlements were surveyed by telephone (T). • ***Not surveyed:*** Acipinar (2.8km from the pipeline). • ***Not on map:*** Alcioren			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Golcuk (L) (B) (T)			
• ***Demographics:*** there are 30 inhabitants with seasonal migration of 60%. • ***Safety:*** the settlement is situated 2.6km north of the pipeline. The nearest house is 2.4km from the pipeline. • ***Project attitude:*** according to the Muhtar the inhabitants are generally positive towards the project and have no major concerns. • ***Land ownership & use:*** 90% of land is leased by inhabitants. It is assumed that few land title deeds are held. No seasonal grazing or irrigation takes place. • ***Settlement livelihood:*** agriculture, hunting, transport and local government are all sources of livelihood.	***Land*** Potential complications in expropriation process. ***Hunting*** Temporary reduction in game due to disturbance during construction.	**See Overview of Land Acquisition Process in Appendix C9.** Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than	**See Overview of Land Acquisition Process in Appendix C9.** **Significance cannot be established at this time**

Social Impact Table 35 (Map 35C) (KPs 675 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

• ***Availability & skills:*** inhabitants have previous experience of the Iran-Ankara natural gas project. • ***Accessibility:*** it is 16 km to Hafik, the district centre. The settlement is accessible all year round. • ***Information provision:*** Turkish is the main. 99% of the population is literate. • ***Infrastructure:*** piped water is supplied to households. • ***Settlement problems:*** low incomes, debt and inadequate childcare are all problems in the settlement.	***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Accessibility to recruitment*** Decreased access to recruitment process	recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. . Winter road closures, seasonal migration and poor transport will be taken into account in the recruitment strategy.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Celalli (L) (S)			
• ***Demographics:*** there are 180 inhabitants within 40 households. Seasonal migration occurs. • ***Safety****:* the settlement is situated 2.2km from the pipeline. • ***Health:*** the sewerage system is poor, leading to health problems. Dumping of garbage into the river has led to contamination. • ***Project attitude:*** the attitude is generally positive as inhabitants believe it will benefit Turkey. However, the inhabitants experienced problems during the construction of the natural gas pipeline, including	***Land*** Potential complications in expropriation process. ***Construction hazards: animals***	**See Overview of Land Acquisition Process in Appendix C9.** **Livestock crossings** will be established at locations	**See Overview of Land Acquisition Process in Appendix C9.** **Potential for accidents involving livestock.**

Social Impact Table 35 (Map 35C) (KPs 675 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

lack of payment or low payments for expropriated land that are still unresolved. • ***Land ownership & use:*** 50% of land is communally owned and 30% is privately owned by inhabitants. Land owners do not possess title deeds (only right of possession) for their land. Seasonal grazing occurs but there is no irrigation. • ***Settlement livelihood:*** animal husbandry activities (cattle, sheep, goats & poultry) satisfy the daily requirements of the households in the settlement. Scarcity of agricultural land means that the dry agriculture activities undertaken are not able to sustain the population. Bee keeping is also undertaken. • ***Availability & skills:*** available skills include heavy vehicle drivers, drivers and welders. 18% of the population would accept a temporary job working on the pipeline construction. • ***Accessibility:*** it is 20km to Hafik district centre. There is good year round accessibility as the road is asphalted. • ***Information provision:*** 95% of the population is literate. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular with regular water cuts. There is no alternative water source. There is an electricity supply, but no sewerage or waste disposal systems. • ***Services:*** there is no primary school as there are insufficient students, instead children travel to the district centre of Hafik. There is a health care centre, a small market, gendarmerie station and an agricultural credit cooperative in the settlement. • ***Settlement problems:*** there is a lack of water, low incomes, out-migration and poor sewerage. It is a relatively poor settlement.	Trench poses safety hazard for livestock ***Health*** Potential health impacts on construction workers. ***Skills & resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials ***Accessibility to recruitment*** Decreased access to recruitment process ***Negative experience*** Possible **opposition** to project and **increased sensitivity** to any negative impacts.	agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Information is highlighted to Contractor** so that they can ensure that their workers are protected. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during	Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No residual impact.** **Potential positive benefits** to local settlements. **No residual impact expected** Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Social Impact Table 35 (Map 35C) (KPs 675 – 696.4): Imranli Karst Area to North-West of Yavu Settlement, Sivas Province

		construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings.**

Environmental Impact Table 36 (Maps 36A and 36B) (KPs 696.4 – 713.3): North-East of Sivritepe Settlement to West of Kanligolet (Uctepe) Irrigation Pond, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Typic Calcixerolls on most plains surfaces. • Mesic Clayey-skeletal Shallow Xerochrepts on plateau scarps. • Minor inclusions of Rhodoxeralfs on some plains locations.	Main potential impacts: • soil erosion; • sediment yield; • soil productivity; • channel alteration; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings	**MODERATE IMPACT** Soil erosion predicted to be visibly active but no rill and gully formation evident. Furthermore, soil productivity losses are predicted to last generally less than one year after construction, but more than three months for arable land and more than 6 months in grazing pasture), but up to 2 years in upland areas with no formal land use.
Landscape and Visual			
The route diverges from the NGP at KP 690. At Sivritepe settlement, the route turns sharply south and crosses the Tatli River, a broad, stony-bedded river in a wide floodplain used predominantly for agriculture but with scattered groups of mature trees. Continuing south past KP 695 it crosses flat or slightly rolling terrain, still on gypseous soils, which are used for non-intensive cereal production, except as it crosses the valleys of the Aci River and Kanli Creek where irrigated cropland occurs. Landscape sensitivity is low. BVS-038 and BVS-039 will be located at KP 702.3 and KP 713.7 on cultivated land. Approximately 350m^2 of permanent landtake required for each station. A new access road will be constructed of c. 35m in length to each site.	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. May be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. Short-term visual impact on non-marl portions of the route. Visual liabilities of the NGP, which was not reinstated, are potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel.	It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. A two-phase approach to reinstatement in the vicinity of the NGP will be adopted (see the RP, Appendix C2). Phase 1 will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems; and Phase 2 will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC	**INDIRECT POSITIVE IMPACT** in areas where the BTC and NGP corridors are reinstated. **MINOR IMPACT** in the short-term where the corridor overlies thin marl soils, as these are unlikely to reinstate to a high standard. Exposed marl may retain its whitish colour and show as a white line across the landscape. However, as the landscape is not considered sensitive, the overall impact is minor.

Environmental Impact Table 36 (Maps 36A and 36B) (KPs 696.4 – 713.3): North-East of Sivritepe Settlement to West of Kanligolet (Uctepe) Irrigation Pond, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	corridor in this section of the route impacted by the presence and proximity of the NGP. In particular, specific reinstatement measures will be required on adjacent agricultural land, for example in areas of poor topsoil management. Responsibilities between the NGP and BTC Contractors are described in the RP (Appendix C2). Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as coir fibre.	
Surface Waters			
The route crosses Tatli River for the second time on this map. River channel is irregular and meanders with a parabolic cross-section. Crossing point is at the meander inflection point. Alternating bars are present. Bank-full width is approximately 40m, although the floodplain width is between 1 and 5 river widths. Bed consists of gravel and cobbles and the flow is intermittent, of a uniform and tranquil type. There is no riparian vegetation and bank-side vegetation comprises bunch grass and shrubs. Uctepe and Kukkuk settlements lie c. 2.5km and 4km downstream of crossing point, respectively.	Direct disturbance through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in already poor water quality. Potential for short-term sedimentation and turbidity (if flowing). Potential impacts on downstream ecology and water abstracted from Tatli River for human use.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, Including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities, such as Uctepe and Kulluk settlements, and provide where necessary if sedimentation and turbidity persist for more than 3 days at the community.	**MINOR IMPACT** Although the water quality classification for Tatli River is unknown, only minor impacts are expected during pipeline construction, as disturbance will be limited to the immediate working area. Sedimentation of Tatli River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.

Environmental Impact Table 36 (Maps 36A and 36B) (KPs 696.4 – 713.3): North-East of Sivritepe Settlement to West of Kanligolet (Uctepe) Irrigation Pond, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Noise			
Sivritepe settlement in Central District is located c. 138m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Sivritepe settlement during soil stripping and welding and lowering activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	**MINOR IMPACT** Short-term noise impacts are expected to occur during soil stripping activities. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.
Archaeology and Cultural Heritage			
Sivritepe 2 (3rd Degree Site*) – flat settlement located within the 100m	Eastern parts of the mound	This site will be fenced throughout	**MINOR IMPACT**

Environmental Impact Table 36 (Maps 36A and 36B) (KPs 696.4 – 713.3): North-East of Sivritepe Settlement to West of Kanligolet (Uctepe) Irrigation Pond, Sivas Province

Corridor. No architectural remains are visible on the surface. * This site has not yet been registered by the MoC and is provisionally assigned this classification. Sivritepe 2 has been proposed for registration by the regional preservation council The following have been proposed for registration by the regional preservation council: (i) Sivritepe Graveyard; (ii) Bestepeler Village cemetery	are located within the 100m Corridor and may suffer indirect impacts from construction activities that will affect the visual/historical setting of the site.	the construction period. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	Assuming Sivritepe 2 is fenced, impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Social Impact Table 36 (Map 36C) (KPs 696.4 – 713.3): North-East of Sivritepe Settlement to West of Kanligolet (Uctepe) Irrigation Pond, Sivas Province

MAP 36: PROJECT INFORMATION			
There are no pump stations or construction camps in area. There is one block valve station.			
MAP 36: MAP HIGHLIGHTS			
• Several rivers with downstream settlements bisect pipeline. • Two large irrigation ponds are located in the area, upstream of the pipeline. • Local access roads link settlements. • Main land uses include rain fed agriculture and irrigated agriculture, with a small amount of pasture.			
MAP 36: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** four settlements on this map will be directly impacted by the pipeline project (Sivritepe, Uctepe, Harmancik, Bestepe). They will all have land intersected by the proposed pipeline (L). (Sivritepe and Bestepe) are within 500m of the pipeline route (D). Sivritepe is also within 2km of the block valve station (B). None are within 5km of a construction camp or pump station. Settlements impacted by traffic have not yet been identified. One settlement is downstream of a river crossing (Kulluk) (R). • ***Surveyed:*** one settlement (Sivritepe) was surveyed in the field and two were surveyed by telephone (T). • ***Disclosure Meeting Location***: Bestepe			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Sivritepe (L) (D) (B) (S)			
• ***Demographics:*** 230 inhabitants with 48 households. • ***Safety****:* the settlement is situated 400m from the pipeline, the nearest house is 100m from the pipeline. • ***Project attitude:*** attitudes are positive. 36% of the population have expectations of direct employment opportunities. • ***Land ownership:*** 50% of the land is privately owned by inhabitants. In addition, 25% is leased by inhabitants, and 25% is communal grazing. There is no irrigation. • ***Settlement livelihood:*** sources of livelihood include agriculture, transport and animal husbandry (cattle and horses). • ***Availability & skills:*** drivers, food service and welders are available. 64% of the population would accept temporary employment on the	***Construction hazards : human*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

There is also a common depot that provides an alternative water source. • ***Settlement problems:*** the roads are poor, there is inadequate access to water and there are infrastructure problems.	***Land*** Potential complications in expropriation process. ***Accessibility to recruitment*** Decreased access to recruitment process	**See Overview of Land Acquisition Process in Appendix C9.** Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**See Overview of Land Acquisition Process in Appendix C9.** **No residual impact expected**

Environmental Impact Table 37 (Maps 37A and 37B) (KPs 713.3 – 733.9): Tutmac Proposed Irrigation Pond to Alacorak and Ulas Lakes, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils types from the previous section continue in this section of the route: • Mesic Typic Calcixerolls on most plains surfaces. • Mesic Clayey-skeletal Shallow Xerochrepts on plateau scarps. • Minor inclusions of Rhodoxeralfs on some plains locations.	Main potential impacts: • soil erosion; • sediment yield; • soil productivity. Other potential impacts include: • channel alteration; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	**MODERATE IMPACT** Soil erosion predicted to be visibly active but no rill and gully formation evident. Furthermore, soil productivity losses are predicted to last generally less than one year after construction, but more than three months for arable land and more than 6 months in grazing pasture), but up to 2 years in upland areas with no formal land use.
Landscape and Visual			
The route crosses flat or slightly rolling upland stepped plateau, still on gypseous soils, which are used for non-intensive cereal production. North of Ulas, the flat landscapes are interrupted by a series of rocky ridges rising sharply from the plain like dragons' backs, and closer to the town the route passes between a number of shallow gypseous lakes, fringed with reedbeds and trees. Landscape is generally unremarkable. While the ridges themselves are spectacular, the agricultural surroundings and electricity lines detract considerably from the scene. Similarly, while some of the lakes are attractive, those closest to the route are not – being seasonal and suffering from degradation associated with the urban fringe of Ulas. South of Ulas, the route crosses a gently-rising area of intensive but non-irrigated arable land. At KP 722, a single, 100m high scarp separates two levels of plateaux.	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. May be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. Short-term visual impact on non-marl portions of the route.	Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as coir fibre.	**MINOR IMPACT** Exposed marl may retain its whitish colour and show as a white line across the landscape. However, as the landscape is not considered sensitive and is tolerant of change, the overall impact is minor.
Ecology			
Protected Areas (Potential) Ulas and Alacorak Lakes, a series of five lakes being considered by the Ministry of Environment (MoE) as an Internationally Important Wetland under the Ramsar Convention, are located c. 1.2km north-west and c.	See Potential Impacts below.	See Mitigation Measures below.	See Residual Impacts below.

Environmental Impact Table 37 (Maps 37A and 37B) (KPs 713.3 – 733.9): Tutmac Proposed Irrigation Pond to Alacorak and Ulas Lakes, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
930m south-east of the 100m Corridor. The three small lakes appear to be permanently wet, while the largest lake is at best seasonal having been dry for a long time at the point of survey on 22.05.2001. Importantly, the lakes appear to act as a whole with birds moving around freely between them particularly at times of disturbance.			
Important Ecological Factors ESA 33 occurs between KP 728.0 and KP 739.9 and is identified for eight globally-threatened plant species (*Dianthus zederbaueri, Achillea goniocephala*, *Astragalus listoniae, Astragalus cymbibracteatus, Astragalus ulashensis, Glaucium acutidentatum, Centaurea sivasica* and *Cerastium saccardoanum*) occur. A further two globally-threatened plants *(Campanula strigillosa* and *Onobrychis argyrea spp. argyrea*) were recorded just east of the corridor parallel to ESA 33. The IUCN status for these species are given in Table 5.20, Section 5. Ulas and Alacorak Lakes support at least two globally-threatened birds – White-headed Duck and Ferruginous Duck – the former (the most important species present along the route corridor) almost certainly breeds, while the other might have done so. In addition, 14 nationally threatened species were present during the bird survey: Red-necked Grebe 2 pairs; Great Egret 1; Common Shelduck 1; Teal 2; Garganey 6; Shoveler 1 pair; Pochard 3 pairs; Marsh Harrier 2; Common Crane 2; Black Tern 1; Citrine Wagtail 1; Whinchat 3; 7 White–winged Black Terns; Montagu's Harrier 2 pairs. Other species noted, which are neither globally or nationally-threatened, but have protection under the Bern Convention, included Purple Heron 1; Whiskered Tern 2; Ruddy Shelduck 154 plus juveniles; Savi's Warbler 1; Great Reed Warbler 12 singing males; Chough 2. Local people reported that about seven pairs of cranes bred around the lakes in 2001. At the beginning of this map (KP 713.5), 2 Common Crane nationally-threatened) were recorded, although none were observed around the lakes. This sighting is highly likely to be associated with the lakes rather than breeding at the location at which it was observed. The protection	Habitat destruction of plain steppe and habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Ulas and Alacorak Lakes are among the most valuable ecological sites along the route. While the lakes are distant enough from the Pipeline for construction itself not to cause undue disturbance, (one lake in fact borders the town of Ulas), disturbance could arise if pipe dumps, contractor's yards or camps are located in this area. Disturbance from construction personnel walking or driving around the lakes would also be detrimental. Minor temporary disturbances are expected to a globally-threatened mammal during seasonal sensitivities (see	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 33. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW.	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds at Ulas and Alacorak Lakes as disturbance will be kept to a minimum through avoidance of the area. This impact is further minimised as birds have successfully bred despite the close proximity of settlements, the largest being Ulas, and infrastructure, ie a motorway and railroad. **MINOR IMPACT** at most to the Forest Dormouse during the construction period where the specified mitigation measures are applied for the

Environmental Impact Table 37 (Maps 37A and 37B) (KPs 713.3 – 733.9): Tutmac Proposed Irrigation Pond to Alacorak and Ulas Lakes, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
status for species observed at the lakes are given in Table 5.21, Section 5.The degree to which the lakes are used as a staging point by migratory waders and waterfowl is as yet unknown. Forest Dormouse (globally-threatened mammal) was recorded between KPs 719.9 – 725.0. The protection status for this species is given in Table 5.21, Section 5.	EMMP, Appendix C1): • breeding season for the Forest Dormouse is between May and August, but in warmer areas the season may extend beyond this period.	Care will be taken in using fertiliser during re-instatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 33. No construction facilities have been or will be located between KP720 and the Ulas Railway Line. The lakes will be placed out-of-bounds to construction personnel. Preconstruction surveys for the Forest Dormouse of dense woodland in the RoW; if present route clearance will be undertaken during the autumn or winter period.	seasonal sensitivities identified.

Social Impact Table 37 (Map 37C) (KPs 713.3 – 733.9): Tutmac Proposed Irrigation Pond to Alacorak and Ulas Lakes, Sivas Province

MAP 37: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There is one block valve station.

MAP 37: MAP HIGHLIGHTS

- National Highway, unclassified/local access roads, river and energy transmission lines bisect the pipeline.
- Two potential RAMSAR (wetland) sites are located in area along with an irrigation pond (very close to pipeline) and two archaeological sites.
- Main land use is rain fed agriculture. A small amount of irrigated agriculture is undertaken along Tecer River.

MAP 37: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** four settlements on this map will be directly impacted by the pipeline project (Tutmac, Hacimirza, Ikindi, Karasar). They all have land intersected by the proposed pipeline (L). None are within 500m of the pipeline route. No settlements are within 5km of a construction camp or pump station. One settlement (Tutmac) is within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. No settlements are downstream of a river/ creek crossing.

- ***Surveyed:*** one settlement (Karasar) was surveyed in the field (S) and three settlements surveyed by telephone (T).
- ***Not surveyed:*** Ulas (1.5km from the pipeline).
- ***Not on map:*** Ikindi.

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Tutmac (L) (B) (T)			
• ***Demographics:*** there are 169 inhabitants with seasonal migration of 5%. • ***Safety****:* the settlement is situated 1.3km from the pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive towards the project, there are no major concerns. • ***Land ownership & use:*** 40% of land is privately owned by the inhabitants. Irrigation is undertaken and there is no livestock grazing. • ***Settlement livelihood:*** agriculture, bee keeping (three households produce honey for own consumption), transport and education are all sources of livelihood for the settlement. • ***Accessibility:*** it is 30km to Sivas district centre. The settlement has poor accessibility in December and January. • ***Information provision:*** 99% of the population is literate. It should be noted that as there is poor energy supply to the settlement, television	***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Land*** Potential complications in expropriation process.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **See Overview of Land Acquisition Process in Appendix C9.**	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **See Overview of Land Acquisition Process in Appendix C9.**

Social Impact Table 37 (Map 37C) (KPs 713.3 – 733.9): Tutmac Proposed Irrigation Pond to Alacorak and Ulas Lakes, Sivas Province

noted that as there is poor energy supply to the settlement, television is not a reliable information provision tool. • ***Environmental & cultural sites:*** there is a castle nearby. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular with frequent water cuts. There is also a stored water supply and a poor energy supply. • ***Settlement problems:*** poor roads, inadequate access to water and inadequate energy supply are all problems for this settlement.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Block Valve Station*** See Environmental Impact Tables and the Overview of Land Acquisition Process in Appendix C9.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Hacimirza (L) **(T)**			
• ***Demographics:*** there are 92 inhabitants with seasonal migration of 80%. • ***Safety:*** the settlement is situated 2.6km from the pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive but are concerned with regard to how land values will be determined. • ***Land ownership & use:*** 80% of land is privately owned by inhabitants. There are no seasonal grazing or irrigation activities. • ***Settlement livelihood:*** activities include agriculture, forestry, manufacturing and construction. • ***Availability & skills:*** inhabitants have previous mining experience. • ***Accessibility:*** the settlement is 12.4km from the district centre. The settlement has poor quality roads but it is accessible all year. • ***Information provision:*** 70% of the population is literate. • ***Infrastructure:*** piped water is supplied to households. • ***Services:*** there are no health care facilities.	***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Accessibility to recruitment*** Decreased access to recruitment process	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact expected**

Social Impact Table 37 (Map 37C) (KPs 713.3 – 733.9): Tutmac Proposed Irrigation Pond to Alacorak and Ulas Lakes, Sivas Province

• ***Settlement problems:*** problems include poor roads, unemployment, inadequate health care and inadequate childcare.			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Karasar (L) (S)			
• ***Demographics:*** there are 350 inhabitants (and increasing) with 55 households. • ***Safety****:* the settlement is situated 2.5km from the pipeline and the nearest house is 2.4km from the pipeline. • ***Health:*** the sewerage system is poor which impacts on health. • ***Project attitude:*** inhabitants are positive towards the project, however the inhabitants are concerned about damage that may be incurred on infrastructure. 42% are hopeful they will receive employment. • ***Land ownership & use:*** 80% of the land is owned privately by the inhabitants, another 20% of land is leased by inhabitants. Landowners do not possess title deeds (only right of possession) for their lands. Seasonal grazing and irrigation activities are undertaken. • ***Settlement livelihood:*** agricultural activities (sugar beet, barley, wheat, oat, rye, fruit trees) are carried out for subsistence purposes. Small-scale animal husbandry is the main economic activity. In addition bee keeping and provision of transport services is undertaken. • ***Availability & skills:*** stonemasonry, heavy vehicle drivers, drivers and welders are available. 75% would accept a temporary job working on the pipeline construction. • ***Accessibility:*** the settlement is 16km from Ulas district centre. Transportation is very difficult during the winter due to muddy roads. Roads are closed for 2-3 days during January and February. • ***Information provision:*** 60% of the population is literate. • ***Infrastructure:*** piped water is supplied to households. There is electricity supply but no sewerage or waste disposal systems. • ***Service:*** there is an elementary school with one teacher and a	***Land*** Potential complications in expropriation process. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Skills & resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials	**See Overview of Land Acquisition Process in Appendix C9.** **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and	**See Overview of Land Acquisition Process in Appendix C9.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Potential positive benefits** to local settlements.

Social Impact Table 37 (Map 37C) (KPs 713.3 – 733.9): Tutmac Proposed Irrigation Pond to Alacorak and Ulas Lakes, Sivas Province

travelling midwife. • ***Settlement problems:*** unemployment, low income, insufficient financial resources for local authority and a poor sewerage system are all problems in this settlement.	***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc. ***Accessibility to recruitment*** Decreased access to recruitment process.	sourcing of goods and supplies within Project constraints. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasise oral communication where literacy is low. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact expected.**

Environmental Impact Table 38 (Maps 38A and 38B) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils types from the previous section continue in this section of the route: • Mesic Typic Calcixerolls on most plains surfaces. • Mesic Clayey-skeletal Shallow Xerochrepts on plateau scarps. • Minor inclusions of Rhodoxeralfs on some plains locations. PT 4 will be located at KP 743.9. The site has only recently been selected as the preferred location for this pump station. Baseline soil quality information is therefore absent at this stage	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity. Other potential impacts will include: • channel alteration; • potential for existing soil contamination at the PT 4 site.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • An additional survey to record existing baseline soil conditions will be undertaken at the PT 4 site to identify any areas of existing soil contamination.	**MODERATE IMPACT** Soil erosion predicted to be visibly active but no rill and gully formation evident. Furthermore, soil productivity losses are predicted to last generally less than one year after construction, but more than three months for arable land and more than 6 months in grazing pasture), but up to 2 years in upland areas with no formal land use.
Landscape and Visual			
The route crosses a gently-rising area of intensive, but non-irrigated, arable land before it ascends very gradually through a series of plateaux that are stepped, so that abrupt scarps separate one elevation from the next. This area is the Uzun Plateau, founded mostly on marl, and the rock lends a pale quality to the landscape, largely made up of heavily grazed grassland and montane steppe although scattered areas are cultivated for cereals. The undulating plains are treeless except in and around some settlements and the settlements are small and well-scattered, so that the region has a desolate feeling. Landscape interest is limited by the relatively featureless terrain and barrenness of the gravely, sparsely-vegetated land. Landscape sensitivity is generally low. The undulating and rolling headlands of Cakmakli Creek (elevations	Disturbing Xerochrepts on hills and scarps will expose the underling marl, leaving a persistent whitish line across upland portions of the landscape. This is less important here than in previous locations due to the already eroded condition of the landscape. There will be a relatively large area of visual influence during	Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as coir fibre. PT 4 has been located within the rural environment to minimise its impact on residential properties. The landscape is undulating and opportunities to use the existing landform features to conceal parts of the facility will be further investigated. A careful replanting	**MINOR IMPACT** Exposed marl may retain its whitish colour and show as a white line across the landscape. However, as the landscape is not considered sensitive and is tolerant of change, the overall impact is minor. **MODERATE IMPACTS** Moderate visual impacts on high sensitivity residential

Environmental Impact Table 38 (Maps 38A and 38B) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
between 1,700 and 1,800m) provide areas of local interest. The stream comprises sinuous, shallow channels, which support wide bands of riparian vegetation and meadow and irrigate the surrounding farmland. PT 4 will require a landtake of 18.7 ha. In addition, there will be a temporary campsite during the construction period, which will occupy c. 12.3 ha. The PT 4 site occupies flat terrain c. 2km east of the settlement of Alaca, at an altitude of c. 1,550m. A main road is located c. 5km to the east of the site. The location provides broad vistas dominated by grasslands and rain-fed cereals. Landscape value is low. BVS-040 will be located at KP 752.2 within cultivated land. Approximately, 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 55m in length. Pasakoy settlement lies c. 190m from the site.	construction of PT4, due to the generally flat terrain in which the site is located. The settlement of Alaca will have the clearest views of construction activities. Residential properties on the eastern edge of the settlement will be most affected, as the settlement itself will screen construction activities from the west side of the settlement. Construction activities will also be visible from parts of the settlements of Bogazdere (Kantariz) (3.5km to the north), Kazanpinar (5km to the east) and Patirkoy (3.5km to the south-east). However, only those residents on the edges of the town closest to the PT 4 site are likely to experience views during construction. Potential for short-term visual impact during construction of BVS-040 for villagers in Pasakoy.	scheme will be employed during reinstatement (see the RP, Appendix C2). In addition mitigation measures in Section 6.3 will be applied. Particular attention will be paid to the control of dust, noise and traffic during construction at BVS-040.	properties with medium distance views of PT 4. However, this impact will occur for a limited period during construction (see Section 7.2.2 for an assessment of operational landscape and visual impacts). **MINOR IMPACT** Given the relatively small size of the block valve station and the temporary nature of construction activities, impacts are anticipated to be minor subject to implementation of the specified mitigation measures.
Surface Geology and Geohazards			
Faults Route crosses Deliler Fault, which is a class A fault, south of KP 740. Deliler Fault is c. 100km long with a general trend from NE-SW. The segment of the fault at the crossing point is c. 55km long.	See *Section 8*.	See *Section 8*.	See *Section 8*.

Environmental Impact Table 38 (Maps 38A and 38B) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Surface Waters			
The Ulas-Kurtlukaya Reservoir is a proposed reservoir lying c. 490m west of route, which will receive flows from Cakmakli and Kurtlukayasuyu Creeks.	Potential for indirect disturbance at Ulas-Kurtlukaya Reservoir, due to run-off containing suspended solids from working areas entering Kurtlukayasuyu Creek (< 1km upstream of the reservoir), consequently resulting in a reduction in water quality in the reservoir.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity at Kurtlukayasuyu Creek crossing point, including measures to protect surface waters flowing into the reservoir, such as sediment filters/trapping devices, settling ponds and trench de-watering.	**MINOR IMPACT** Only minor impacts expected, as disturbance will be limited to the immediate working area at Kurtlukayasuyu Creek. Sedimentation of Kurtlukayasuyu Creek will only be visible for less than 3 weeks after construction, with no obscuration of the river bed. This impact will not be transmitted as far as the reservoir.
Ecology			
Important Ecological Factors ESA 34 occurs between KP 735.9 and KP 739.4 and is identified for seven globally-threatened plant species (*Dianthus zederbaueri, Physoptychis haussknechtii, Alyssum lepidoto-stellatum, Campanula strigillosa, Salvia vermifolia, Hypericum thymbrifolium* and *Centaurea sivasica*) and one nationally-threatened species (*Astragalus karputanus*). In addition, four globally-threatened species (*Astragalus cymbibracteatus, Achillea goniocephala, Astragalus listoniae* and *Crocus kotschyanus sp. cappadocicus*) occur just outside the corridor to the SE of this section. One globally-threatened species (*Campanula strigillosa*) occurs just outside the 500m Corridor to the east of KP 747.8. The IUCN status for these species are given in Table 5.20, Section 5. At KP 741.6, 2 Whinchat and 1 Barred Warbler (both nationally-threatened) were recorded. The protection status for these species are given in Table 5.21, Section 5.	Habitat destruction of plain steppe and habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 34. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used,	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts

Environmental Impact Table 38 (Maps 38A and 38B) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during re-instatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 34. Shrubs, thickets and dense vegetation along the RoW will be cleared outside the breeding season for the Whinchat and Barred Warbler.	will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

MAP 38: PROJECT INFORMATION

There is a pump station (PT4) in the area. It is a 18.68 hectare site, located on relatively flat land surrounded by mountainous terrain. Adjacent to the pump station is its temporary construction camp (12.31ha). There is no block valve station in the area.

MAP 38: MAP HIGHLIGHTS

- There are three irrigation ponds in the area.
- Two creeks bisect the pipeline.
- The pump station is located on an active fault line.
- Main land use is rain-fed agriculture with pockets of irrigated agriculture and pasture near creeks.

MAP 38: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** ten settlements will be directly impacted by the pipeline project. Seven will have land intersected by the proposed pipeline (Kurtkaya, Hurriyet, Yesilyet, Devlet Uretme Ciftligi, Yazicik, Bogazdere, Basoren) (L); one settlement (Kantariz) is within 500m of the pipeline route (D). Five settlements (Yazicik, Bogazdere, Akkuzulu, Kazanpinar, Basoren) are within 5km of a pump station (P). Settlements impacted by traffic have not yet been identified. One settlement is downstream of a creek crossing (Kantariz is downstream of the Cakmakli Creek).

- ***Surveyed:*** two settlements (Yazicik, Kazanpinar) were surveyed in the field (S) and seven settlements surveyed by telephone (T).
- ***Not surveyed:*** Kantariz (nearest house is 400m from the pipeline), Akkuzulu.
- ***Not on map:*** Hurriyet, Devlet Uretme Ciftigi, Yazicik, Bogazere, Akkuzulu, Kazanpinar.
- ***Disclosure Meeting Location:*** Basoren

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Kurtkaya/ Kurtlukaya (L) (T)			
• ***Demographics:*** there are 91 inhabitants with seasonal migration of 50%. • ***Safety:*** the settlement is situated 1.2km from the pipeline. • ***Project attitude:*** according to the Muhtar, the inhabitants are generally positive about the project and have no major concerns. • ***Land ownership & use:*** 90% of land is privately owned by the inhabitants. Seasonal grazing occurs and irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (four households produce honey for own consumption), trade and local government	***Construction hazards: animals*** Trench poses safety hazard for livestock	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

produce honey for own consumption), trade and local government area all sources of livelihood. • ***Accessibility:*** the settlement is 11km from Ulas district centre. The settlement has poor accessibility from December to February. • ***Environmental & cultural sites:*** there is a graveyard and forest in the area. • ***Infrastructure:*** piped water is supplied to households. • ***Settlement problems:*** problems include poor roads and low incomes. • ***Other:*** this settlement had low awareness of the pipeline.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility of recruitment*** Decreased access to recruitment process ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No residual impact expected** **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Hurriyet Mah (T) **(L)**			
• ***Demographics:*** there are 375 inhabitants with seasonal migration of 17%. • ***Safety****:* the settlement is situated 1.4km from the pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive about the project and have no major concerns. • ***Land ownership & use:*** 100% of land is privately owned by the inhabitants. No grazing occurs but irrigation activities are	***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

inhabitants. No grazing occurs but irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture (no animal husbandry), bee keeping (two households produce honey for their own consumption), commercial fishing (five households fish as their main source of income), forestry, mining, construction, transport, trade, education and local government are all sources of livelihood. • ***Accessibility:*** the settlement is 14.8km from the district centre. The settlement is accessible all year. • ***Information provision:*** 80% of the population is literate. • ***Environmental & cultural sites:*** Kervansaray is a cultural site. • ***Infrastructure:*** piped water is supplied to households. • ***Settlement problems:*** poor roads, unemployment and inadequate access to water are problems for this settlement.		compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	
	Accessibility of recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Yesilyurt (L) **(T)**			
• ***Demographics:*** there are 293 inhabitants with seasonal migration of 3%. • ***Safety****:* the settlement is situated 3.4km from the pipeline. • ***Disputes:*** there is political instability in the settlement. • ***Project attitude:*** according to the Muhtar, the inhabitants are generally positive towards the project and have no major concerns. • ***Land ownership & use:*** There is no seasonal grazing of settlement livestock and irrigation is undertaken. • ***Settlement livelihood:*** animal husbandry, bee keeping (eight households produce honey as one of many sources of income), trade, education and local government are all sources of livelihood. • ***Accessibility:*** it is 22.5km to the district centre. The settlement has poor accessibility all year round. • ***Information provision:*** 70% of the population is literate. • ***Water infrastructure:*** piped water is supplied to households. • ***Settlement problems:*** there is political instability and unemployment.	***Land*** Potential complications in expropriation process. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc.	**See Overview of Land Acquisition Process in Appendix C9.** **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include using appropriate channels of communication and media and emphasising oral communication where	**See Overview of Land Acquisition Process in Appendix C9.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

		literacy is low.	
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected.**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Yazicik (L) (P) (S) (T)			
• ***Demographics:*** there are 80 inhabitants within 16 households and seasonal migration of 35%. • ***Safety****:* the settlement is situated 5km from the pump station. • ***Disputes:*** there are disputes over natural resources. • ***Project attitude:*** attitudes towards the pipeline project are positive and the pump station is welcomed. Perceived benefits of the pipeline and pump station include employment opportunities in pipeline construction. Perceived problems include concerns over disruption to the harvest during construction. • ***Land ownership at pump station site:*** the site is 18.68ha in size, of which 8.6ha are owned by local residents in Yazicik, and 10ha are owned by local residents in Yesilyurt. • ***General land ownership & use:*** the land for construction is privately owned (by two brothers) and thus there were no concerns regarding expropriation (beyond establishing a fair price and paying on time)	**PUMP STATION IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction of the pump station. See Sections 6 and 7 and the Overview of Land Acquisition Process in Appendix C9. ***Land*** Permanent land expropriation of 6.8ha will occur.	Evaluate the possibility of assigning unused state owned pastureland. **See Overview of Land Acquisition Process in**	Potential loss of land. **See Overview of Land Acquisition Process in Appendix C9.**

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

expropriation (beyond establishing a fair price and paying on time). 50% of land is communal. No irrigation is undertaken. • ***Settlement livelihood:*** agriculture (grain), forestry and education are all sources of livelihood. There is little commercial activity. • ***Availability & skills:*** there is previous experience in motorway construction. • ***Accessibility:*** it is 58 km to the provincial centre of Ulas and 7km to the district centre. The settlement is located on the highway and is accessible all year. • ***Information provision:*** 100% of the population is literate. • ***Environmental & cultural sites:*** Hitittit's Traces is a cultural site. In addition, the settlement has very healthy water that is of environmental significance. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular with frequent water cuts. There is no alternative water source. There is also an electricity supply. • ***Services:*** There is no sewerage system, primary school or health care facilities. • ***Settlement problems:*** problems include financial problems, inadequate access to water, unemployment and inadequate childcare facilities.	***Livelihoods*** Decreased land resources may result in decreased livelihood opportunities. **PUMP STATION CONSTRUCTION CAMP IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction workers	**Appendix C9.** **See Overview of Land Acquisition Process in Appendix C9.** **Monthly community liaison** meetings will be held**.** **Preferential employment opportunities.** **Project to liase** with local health authorities. BTC Company will look at opportunities to cooperate in providing **health awareness training.**	**See Overview of Land Acquisition Process in Appendix C9.** **Low likelihood of significant impacts.** Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures. **Low likelihood of significant health impacts.** **Benefits** from raising health awareness of the workforce (many of whom will be local). Further positive benefits dependent on the scale of community investment activities.

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

	PIPELINE IMPACTS: ***Land*** Potential complications in expropriation process. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Accessibility to recruitment*** Decreased access to recruitment process	**See Overview of Land Acquisition Process in Appendix C9.** **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**See Overview of Land Acquisition Process in Appendix C9.** **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Bogazdere (L) (P) (T)			
• ***Demographics****:* there are 61 inhabitants with seasonal migration of 50%. • ***Safety****:* the settlement is situated 750m from the pipeline and the nearest house is 600m from the pipeline. It is approximately 3.5km from the pump station. • ***Project attitude:*** inhabitants are generally positive towards the project, however they are concerned about potential health issues. They also feel they have not been provided with enough information	**PUMP STATION IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction of the pump station. See Sections 6 and 7 and the Overview of Land Acquisition		

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

They also feel they have not been provided with enough information about the project. Inhabitants would generally welcome the pump station and perceive direct employment opportunities with pipeline construction. Perceived problems include some concern over potential damage to roads and harvest. • ***Land ownership & use:*** 80% of land is privately owned by the inhabitants. Most inhabitants have land titles. Average land holdings surrounding pump station are 19ha with nine plots of land. Primary land use is grain cultivation. There is no grazing. Irrigation is undertaken. • ***Settlement livelihood:*** sources of livelihood include agriculture, bee keeping (fifteen households produce honey as one of many income sources), hunting and trade. • ***Accessibility:*** The settlement is accessible all year. • ***Information provision:*** 90% of the population is literate. • ***Environmental & cultural sites:*** there is a castle in the area. • ***Infrastructure:*** piped water is supplied to households. • ***Settlement problems:*** problems include poor roads and low income. • ***Other:*** inhabitants would like the opportunity to have surplus soil deposited in nominated preferred locations.	Process in Appendix C9.. **PUMP STATION CONSTRUCTION CAMP IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction workers **PIPELINE IMPACTS:** ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	**Monthly community liaison** meetings will be held**.** **Preferential employment opportunities.** **Project to liase** with local health authorities. BTC Company will look at opportunities to cooperate in providing **health awareness training.** Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**Low likelihood of significant impacts.** Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures. **Low likelihood of significant health impacts.** **Benefits** from raising health awareness of the workforce (many of whom will be local). Further positive benefits dependent on the scale of community investment activities. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

	Hunting Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	**Significance cannot be established at this time**
	Accessibility of recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner o need to move hives to a position at least 300m from the route. If	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

		moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Construction hazards: humans Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.
	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage will be compensated for.**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Kazanpinar (P) **(S)**			
• ***Demographics:*** there are 270 inhabitants within 37 households. • ***Safety****:* the settlement is situated 4km from the pipeline and 5 km from the pump station. • ***Health:*** the sewerage system is poor, leading to health implications. • ***General Land ownership & use:*** 65% of land is leased by inhabitants and 32% is owned privately by inhabitants. The	**PUMP STATION IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction of		

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

inhabitants and 32% is owned privately by inhabitants. The inhabitants do not, however, own land in or around the pump station itself. Low levels of grazing occur. There is no irrigation. • ***Project attitude:*** Attitudes towards the pipeline are mixed. The settlement had a negative experience with land acquisition during highway construction, however, they believe that the pipeline will have national and local benefits and has the potential to improve the settlements economic life. Inhabitants would generally would welcome a pump station but not within 3km of the settlement. Perceived benefits of the pipeline and pump station include high employment expectations. Perceived problems associated with the pipeline and pump station include construction work that could increase traffic flow through and near to the settlement. There is also concern that passing workers could consume settlement natural resources without permission. • ***Settlement livelihood:*** livelihood sources include agriculture (grain), trade and animal husbandry (cattle & poultry). • ***Accessibility:*** the settlement is x km from the district centre and is located very close to a national highway, therefore there is good accessibility. • ***Information provision:*** 70% of the population is literate. • ***Infrastructure:*** piped water is supplied to households however, the supply is irregular with frequent water cuts. A community well and a local spring provide alternative water sources of water. • ***Services:*** there is a primary school but no health care facilities. • ***Settlement problems:*** poor sewerage system, poor transportation and inadequate water supply are all problems for the settlement.	the pump station. See Sections 6 and 7 and the Overview of Land Acquisition Process in Appendix C9.. **PUMP STATION CONSTRUCTION CAMP IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction workers **PIPELINE IMPACTS:** ***Accessibility to information*** Sectors of the population may not have access to project related information on	**Monthly community liaison** meetings will be held**.** **Preferential employment opportunities.** **Project to liase** with local health authorities. BTC Company will look at opportunities to cooperate in providing **health awareness training.** **Communication with settlement** must take into account settlement characteristics to ensure equal access to information	**Low likelihood of significant impacts.** Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures. **Low likelihood of significant health impacts.** **Benefits** from raising health awareness of the workforce (many of whom will be local). Further positive benefits dependent on the scale of community investment activities. **No residual impact expected**

SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Basoren (L) (P) (D) (T)			
• ***Demographics:*** 322 inhabitants reside in the settlement, 10% seasonally migrate. (If the settlements' Akkuzulu Quarter is included, there are 576 inhabitants and 53 households). • ***Safety****:* the settlement is situated 650m from the pipeline and 5km from the pump station. The nearest house is 50m from the pipeline. • ***Health:*** the poor sewerage system impacts on health. • ***Land ownership & use:*** 50% of land is privately owned by the inhabitants and 50% is community owned. There is no seasonal grazing and no irrigation. The inhabitants do not own land in or around the pump station. • ***Project attitude:*** the attitude towards the pipeline is generally positive, however the settlements have requested that a liaison officer be nominated to receive concerns from inhabitants for any losses that might arise during construction. Damage to the local area caused by construction of the natural gas pipeline was considerable and damage was not reinstated. Inhabitants generally welcome the pump station. Perceived benefits of the pipeline and pump station include employment opportunities in pipeline construction and indirect employment opportunities in the provision of goods and services to the camp and materials for construction. The perceived problems include concerns over potential damage to land and crops. • ***Settlement livelihood:*** agriculture, bee keeping (two households produce honey as one of many economic sources), construction, trade and local government are the main sources of livelihoods. • ***Accessibility:*** it is 15km to Altinyayla district centre. Roads are occasionally closed in the winter months of December to February	**PUMP STATION IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction of the pump station. See Sections 6 and 7 and the Overview of Land Acquisition Process in Appendix C9.. **PUMP STATION CONSTRUCTION CAMP IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction workers	**Monthly community liaison** meetings will be held**.** **Preferential employment opportunities.** **Project to liase** with local health authorities. BTC Company will look at opportunities to cooperate in providing **health awareness**	**Low likelihood of significant impacts.** Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures. **Low likelihood of significant health impacts.**

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

occasionally closed in the winter months of December to February. • ***Information provision:*** 60% of the population is literate. • ***Infrastructure:*** piped water is supplied to households, however, supply is irregular with frequent water cuts. A settlement fountain provides an alternative water source. • ***Settlement problems:*** roads are poor, there is inadequate access to water, unemployment and a poor sewerage system.	**PIPELINE IMPACTS:**	**training.**	**Benefits** from raising health awareness of the workforce (many of whom will be local). Further positive benefits dependent on the scale of community investment activities.
	Construction hazards: human Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.
	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage will be compensated for.**
	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 38 (Map 38C) (KPs 733.9 – 751.3): North-East of Kurtlukaya Settlement to South of Basoren Settlement, Sivas Province

	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Land Potential complications in expropriation process.	**See Overview of Land Acquisition Process in Appendix C9.**	**See Overview of Land Acquisition Process in Appendix C9.**
	Drinking water Potential for contamination of drinking water by sediment or accidental spills	**Alternative sources of water** will be provided during construction to settlements that use water channels for drinking that are crossed by the construction activities.	**No residual impact.**
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
		Groundwater During land acquisition, any	**If there is any long term impact on water sources**,

		ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	appropriate alternatives to be provided by the Project.
	Accessibility to Recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected.**
	Negative experience Possible **opposition** to project and **increased sensitivity** to any negative impacts.	BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are rapidly identified. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings.**	Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Environmental Impact Table 39 (Maps 39A and 39B) (KPs 751.3 – 767.5): North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Loamy-skeletal Xerochrepts on sloping uplands. These are highly eroded on the scarp (see Landscape and Visual below). • Fine-silty Xerofluvents near channels supporting pasture and riparian vegetation. • Mesic Typic Calcixerolls on sloping and gently sloping lands planted to rainfed cereals.	Main potential impacts: • soil erosion; • sediment yield; • soil productivity. Other potential impacts will include: • channel alteration; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	**MODERATE IMPACT** Soil erosion predicted to be visibly active but no rill and gully formation evident. Furthermore, soil productivity losses are predicted to last generally less than one year after construction, but more than three months for arable land and more than 6 months in grazing pasture), but up to 2 years in upland areas with no formal land use.
Landscape and Visual			
The route continues to traverse a series of stepped plateaux founded mostly on marl, and the rock lends a pale quality to the landscape which is largely made up of heavily grazed grassland and montane steppe although scattered areas are cultivated for cereals. The undulating plains are treeless except in and around some settlements and the settlements are small and well-scattered, so that the region has a desolate feel. The Sekerpinar River has well-developed marshland in places. Further south, the route picks its way between a series of small rivers flowing through wide, flat-bottomed, verdant valleys, bounded either side by very steep, almost cliff-like, scarp slopes of exposed marl that show white in the landscape. These valleys are covered with buttercups during the spring, forming bright yellow swathes across the landscape, and clumps of poplars	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. May be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. This is less important here than in previous locations due to the already eroded condition of the landscape.	Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as coir fibre.	**MINOR IMPACT** Exposed marl may retain its whitish colour and show as a white line across the landscape, although this may be less conspicuous here than in previous locations due to the already eroded condition of the landscape.

Environmental Impact Table 39 (Maps 39A and 39B) (KPs 751.3 – 767.5): North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
and willows are present. Larger settlements occur along the valley edges. The route keeps to the higher ground where the plains are stony, open, sparsely-vegetated, and largely featureless. Landscape interest is limited, except where views include the green river valleys.			
Surface Waters			
Sekerpinar Reservoir has been proposed for construction by the DSI and will be situated c. 960m east of the route. The pond will receive flows from Sekerpinar River.	Potential for indirect disturbance at Serkerpinar Reservoir, due to run-off containing suspended solids from working areas entering Sekerpinar River, resulting in a reduction in water quality in the reservoir.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to avoid sedimentation and turbidity at Sekerpinar River, such as sediment filters/trapping devices, settling ponds and trench de-watering.	**MINOR IMPACT** Only minor impacts expected, as disturbance will be limited to the immediate working area. Sedimentation of Sekerpinar River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed. This impact will not be transmitted as far as the reservoir.
Ecology			
Important Ecological Factors ESA 52 is identified for the presence of a range of endemic plant species including the nationally- and globally-threatened *Dianthus zederbaueri.* ESA 35 occurs between KP756.2 and KP 757.5 and is identified for two globally-threatened plant species (*Bornmuellera cappadocica* and *Crocus kotschyanus sp. cappadocicus*). In addition, two other globally-threatened plants (*Campanula strigillosa* and *Astragalus cymbibracteatus*) occur just east of the corridor parallel to this ESA. The IUCN status for these species are given in Table 5.20, Section 5. A riparian marsh just south of the settlement of Kurkcukyurt, along the Sekerpinar Creek, is of importance as a migratory staging point for the globally-threatened Great Snipe. The marsh also held several pairs of breeding waders (Redshank and Lapwing) and Mallard and good numbers	Although the route has been re-aligned to avoid the most important parts of the marsh, habitat destruction of plain steppe may still result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened Whinchat during nesting, feeding or indirectly, through habitat loss if construction is	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 52 and ESA 35. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for globally and nationally-threatened birds, where pipeline construction is

Environmental Impact Table 39 (Maps 39A and 39B) (KPs 751.3 – 767.5): North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
of riparian passerines including Whinchat (nationally-threatened). The protection status for this species is given in Table 5.21, Section 5.	undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods. Potential for direct disturbance to a globally-threatened migratory species. Autumn passage of the Great Snipe is between August and September, though it may continue into November. Therefore, potential for direct disturbance during this period for birds using Serkerpinar as a staging point.	is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during re-instatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 52 and ESA 35. The marsh habitat will be protected from heavy machinery by the use of moveable equipment mats pads. It will be ensured that the marsh is not drained accidentally as a result of construction. Preconstruction survey to establish the extent of resource utilisation of Serkerpinar River as a staging post by the Great Snipe. Specific mitigation plan to be	scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Environmental Impact Table 39 (Maps 39A and 39B) (KPs 751.3 – 767.5): North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		developed based on the outcome of the survey, once level of resource utilisation is established. Shrubs and dense vegetation along the RoW at Serkerpinar River will be cleared outside the breeding season for the Whinchat.	
Noise			
Pasakoy settlement in Altinyayla District is located c. 138m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Pasakoy settlement during soil stripping and welding and lowering activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for	**MINOR IMPACT** Short-term noise impacts are expected to occur during soil stripping activities. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.

Environmental Impact Table 39 (Maps 39A and 39B) (KPs 751.3 – 767.5): North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	
Archaeology and Cultural Heritage			
Hoyuktepe (East) (3rd Degree Site*) is a flat settlement that lies north-west of the route near KP 765.0. Roman ceramic shards are found on the surface of this site. Yeldegirmeni Tumulus - 1st Degree The following have been proposed for registration by the regional preservation council: (i) Hoyoktepe; (ii) Pasakoy (iii) Ciftetepe; (iv) Tumulus; (v) Bescardak * This site has not yet been registered by the MoC and is provisionally assigned this classification.	Potential for site to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	The pipeline has been re-routed to avoid this site. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Social Impact Table 39 (Map 39C) (KPs 751.3 – 767.):
North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

MAP 39: PROJECT INFORMATION			
A pump station (PT4) that is located on Map38 is within 5km of one settlement in this area. There is also a block valve station in the area.			
MAP 39: MAP HIGHLIGHTS			
• River bisects pipeline and flows into Sekerpinar pond. • There are four archaeological sites in area. • Main land uses are pasture and rain fed agriculture.			
MAP 39: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** seven settlements will be directly impacted by the pipeline project. All will have land intersected by the proposed pipeline (Pasakoy, Mutubey, Kurkcuyurt, Harmandali, Yesilyurt Mah, Deliilyas Mah, Safak) (L). Two (Pasakoy and Harmandali) are within 500m of the pipeline route (D); none are within 5km of a construction camp; and one Yesilyurt Mah is within 5km of a pump station (P). Pasakoy is within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. One settlement is downstream of a river crossing (Kurkcuyurt) • ***Surveyed:*** five settlements (Pasakoy, Mutubey, Kurkcuyurt, Harmandali, Yesilyurt Mah) were surveyed in the field (S) and three settlements surveyed by telephone (T). • ***Not on map:*** Deliilyas, Safak			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Pasakoy (L) (D) (B) (S)			
• ***Demographics:*** there are 250 inhabitants with 30 households. • ***Safety:*** the settlement is situated 400m from the pipeline and the nearest house is 80m from the pipeline. • ***Health:*** the poor sewerage system causes health problems. • ***Disputes:*** tensions exist between parts of the community and the Muhtar. • ***Project attitude:*** the general attitude towards the project is positive. 55% of those interviewed are optimistic about employment opportunities and 18% about land compensation. However, there is considerable concern over the safety of children and animals during construction. • ***Land ownership & use:*** 50% of land is privately owned by inhabitants, the remaining 20% is communal pasture and 30%	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 39 (Map 39C) (KPs 751.3 – 767.):
North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

forests. Landowners do not possess title deeds (only right of possession) for their lands. Seasonal grazing of cattle and sheep occurs. There is no irrigation. • ***Settlement livelihood:*** animal husbandry (cattle) is the main economic activity. Dry–agriculture (barley & wheat) is undertaken, however although there are vast lands available for carrying out agricultural activities, insufficiency of labour force and barrenness result in non-cultivation of fields. • ***Availability & skills:*** heavy machine operators, heavy vehicle drivers, drivers and security are available. 82% of those interviewed would accept a temporary job on the pipeline construction. • ***Accessibility:*** the distance to Altinyayla district centre is 12km. Transportation is difficult during the winter due to mud. Roads are blocked with snow for intervals during January and February. • ***Information provision:*** 80% of the population is literate. • ***Infrastructure:*** piped water is supplied to households however supply is irregular with occasional water cuts. There is no alternative water source. There is an electricity supply, but no sewerage or waste disposal systems. • ***Services:*** there is a primary school with two teachers and a travelling midwife, however, there is no health care centre. • ***Settlement problems:*** transport difficulties, lack of water, unemployment and a poor sewerage system are all problems for the settlement. It is a relatively poor settlement.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Land*** Potential complications in expropriation process. ***Accessibility to recruitment*** Decreased access to	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **See Overview of Land Acquisition Process in Appendix C9.** Winter road closures, seasonal migration and poor transport will be **taken into**	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **See Overview of Land Acquisition Process in Appendix C9.** **No residual impact expected**

Social Impact Table 39 (Map 39C) (KPs 751.3 – 767.):
North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

	recruitment process ***Skills and resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials ***Block Valve Station*** See Environmental Impact Tables and the Overview of Land Acquisition Process in Appendix C9.	**account** in the recruitment strategy. **Information is highlighted to Contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints.	**Potential positive benefits** to local settlements. .
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Mutubey (L) **(S)**			
• ***Demographics:*** 500 inhabitants, with 90 households. • ***Safety****:* settlement is situated 1.1km from pipeline and the nearest house is 1km from the pipeline. • ***Health:*** poor sewerage system causing poor health. • ***Project attitude:*** generally positive, providing necessary measures are put in place to ensure the safety of children during construction; and employment opportunities and expropriation payments are maximised. • ***Land ownership & use:*** 50% of land is privately owned by inhabitants and the remaining is communal pastures and forests (40%). Landowners do not possess title deeds (only right of possession) for their lands. Seasonal grazing occurs. There is no irrigation.	***Land*** Potential complications in expropriation process ***Construction hazards: animals*** Trench poses safety hazard for livestock.	**See Overview of Land Acquisition Process in Appendix C9.** **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**See Overview of Land Acquisition Process in Appendix C9.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 39 (Map 39C) (KPs 751.3 – 767.):
North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

irrigation. • ***Settlement livelihood:*** dry agriculture (grain) for own consumption, animal husbandry (cattle, sheep & poultry), and construction. • ***Availability & skills:*** heavy vehicle drivers, drivers and welders are available. • ***Accessibility:*** 14km to Altinyayla district centre. Transportation is very difficult during winter due to muddy roads. Roads are blocked by snow for intervals during January, February and March. • ***Information provision:*** 80% of the population is literate. • ***Infrastructure:*** piped water is supplied to households however supply is irregular with frequent water cuts. There is no alternative water source. • ***Services:*** there is electricity supply but no sewerage or waste disposal systems. There is also an elementary school with seven teachers and 130 students, and a travelling midwife. However, there is no health care centre. • ***Settlement problems:*** poor sewerage system, disease, unemployment and inadequate waste disposal.	***Accessibility of recruitment*** Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Kurkcuyurt (L) **(S)**			
• ***Demographics:*** there are 700 inhabitants within 90 households. Many people migrate to provincial centres due to lack of arable land. • ***Safety:*** the settlement is situated 1.25km from the pipeline and the nearest house is 850m from the pipeline. • ***Health:*** the poor sewerage system causes ill health. • ***Project attitude:*** attitudes are generally positive, particularly if the project provides employment opportunities. • ***Land ownership & use:*** 90% of land is privately owned by the inhabitants and the remaining 10% is communal land. Landowners do not possess title deeds (only right of possession) for their lands. Arable land is limited and seasonal grazing occurs. There is no irrigation.	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in expropriation process.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **See Overview of Land Acquisition Process in Appendix C9.**	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of Land Acquisition Process in Appendix C9.**

Social Impact Table 39 (Map 39C) (KPs 751.3 – 767.):
North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

• ***Settlement livelihood:*** animal husbandry (cattle, sheep & poultry) is the main economic activity. Minimal agricultural activities (grain) are undertaken. There are also some trade and education activities. • ***Availability & skills:*** food services, heavy vehicle drivers, tree feller, drivers and typesetter are available. • ***Accessibility:*** it is 13km to Altinyayla district centre. Roads become muddy during winter and are sometimes blocked by snow January and February, therefore accessibility is poor during this period. • ***Information provision:*** 80% of the population is literate. • ***Infrastructure:*** piped water is supplied to households, there is an electricity system, however there are no sewerage or waste disposal systems. • ***Services***: there is a primary school that has the capacity to become a regional boarding school. It currently has seven teachers and 88 students. There is an un-staffed health care centre, a travelling midwife, and the settlement has a small market and a flourmill that are sufficient to meet the needs of local people. • ***Settlement problems:*** problems include transport difficulties, unemployment, poor sewerage system, (is a relatively wealthier and larger settlement, however in recent years unemployment has resulted in intensive emigration).	***Accessibility to recruitment*** Decreased access to recruitment process ***Health*** Potential health impacts on construction workers.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. **Information is highlighted to contractor** so that they can ensure that their workers are protected.	**No residual impact expected** **No residual impact**.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Harmandali (L) (D) (S)			
• ***Demographics:*** there are 300 inhabitants within 73 households. • ***Safety:*** the settlement is situated 650m from the pipeline, the nearest house is 500m from the pipeline. • ***Project attitude:*** the attitude is generally positive. Settlements have high expectations of expropriation payments and upgrading of settlement roads by the construction company. 54% of those interviewed welcome potential employment opportunities, 36% see no benefits. • ***Land ownership and use:*** 60% of land is privately owned by the	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

inhabitants with another 20% leased by the inhabitants. Landowners, however, do not possess title deeds (right of possession) for their land. Harmandali has established a water cooperative to allow wet agriculture/farming. There is no irrigation. • ***Settlement livelihood:*** dry agricultural activities (grain) are undertaken, however settlements are attempting to convert this to wet agricultural activities. In addition the inhabitants undertake bee keeping and provide transport. Cattle, sheep & poultry are farmed. • ***Availability & skills:*** food services, heavy vehicle drivers, mechanics, drivers, tree fellers and welders are available. • ***Accessibility:*** it is 16km to Altinyayla district centre. Transportation is very difficult during winter with muddy roads. The road is closed due to snow during January and February. • ***Information provision:*** 90% of the population is literate. • ***Infrastructure:*** piped water is supplied to households however the supply is irregular. There is no alternative water source. There is an electricity system and sewerage system, but no waste disposal system. • ***Services:*** there is a primary school with six teachers and 120 students; and a travelling midwife, but no health care centre. There is a small market and a coffee house. • ***Settlement problems:*** problems include unemployment, transport difficulties and poverty. It is considered to be a relatively poor settlement, however the local community is exerting effort to improve the settlement eg establishment of a water supply cooperative.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Land*** Potential complications in expropriation process. ***Bees*** Disturbance of any stationary hives located within 300m of the route.	**Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **See Overview of Land Acquisition Process in Appendix C9.** **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300 metres from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of Land Acquisition Process in Appendix C9.** **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be

Social Impact Table 39 (Map 39C) (KPs 751.3 – 767.):
North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

		position for 15-20 days prior to moving back close to their original location.	facilitated by the Projects complaints procedure.
	Accessibility to recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Skills and resources Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials.	**Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints.	**Potential positive benefits** to local settlements

		construction.	
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Safak (L) **(T)**			
• ***Demographics:*** there are 510 inhabitants with seasonal migration of 10%. • ***Project attitude:*** attitudes are positive, although the inhabitants would like to receive more information on the proposed pipeline. • ***Land ownership & use:*** 90% of the land is privately owned by the inhabitants. Seasonal grazing and irrigation activities occur. • ***Settlement livelihood:*** agriculture, fishing, transport, tourism, bee keeping (150 households produce honey for their own consumption), construction, trade, education and local government are all sources of livelihood. • ***Accessibility:*** The settlement is accessible all year. • ***Information provision:*** 40% of the population is literate. Television, radio and the newspaper are the best information provision tools. • ***Infrastructure:*** piped water is supplied to households. • ***Settlement problems:*** problems include poor roads and unemployment.	***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Social Impact Table 39 (Map 39C) (KPs 751.3 – 767.):
North of Pasakoy Settlement to South of Harmandali Settlement, Sivas Province

	Construction hazards: animals Trench poses safety hazard for livestock	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

Environmental Impact Table 40 (Maps 40A and 40B) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Loamy-skeletal Xerochrepts on sloping uplands. • Mesic Typic Calcixerolls on undulating lands, especially those planted to rainfed cereals. • Fine-silty Xerofluvents near channels supporting pasture and riparian vegetation.	**Main potential impacts include:** • soil erosion; • sediment yield; • soil productivity; • channel alteration; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	**MINOR IMPACT** Soil productivity losses are predicted to last less than 3 months after construction is completed. Furthermore, soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
The route continues to keep to the higher ground where the plains are stony, open, sparsely-vegetated, and largely featureless, picking its way between a series of small rivers flowing through wide, flat-bottomed, extremely green valleys, bounded either side by very steep, almost cliff-like, scarp slopes of exposed marl that show white in the landscape. These valleys are covered with buttercups during the spring, forming bright yellow swathes across the landscape, and clumps of poplars and willows are present. Larger settlements are present along the valley edges. Landscape interest is limited and sensitivities low, except where views include the green river valleys where they become moderate to high.	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. This may be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. This is less important here than in previous locations due to the already eroded condition of the landscape.	Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as choir fibre.	**MINOR IMPACT** Exposed marl may retain its whitish colour and show as a white line across the landscape, although this may be less conspicuous here than in previous locations due to the already eroded condition of the landscape.
Ecology			
Important Ecological Factors ESA 53 (KP 778.22 – 779.17) is identified due to the presence of the nationally threatened, endemic *Paronychia cataonica.*	Habitat destruction may result in the loss of individuals from the population of the	Threatened plant species will be identified and located during pre-construction surveys within ESA	**MODERATE IMPACTS** due to short-term disturbance to important flora within the ESA

Environmental Impact Table 40 (Maps 40A and 40B) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	nationally threatened species.	53. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW.	53. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2).

Social Impact Table 40 (Map 40C) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

MAP 40: PROJECT INFORMATION			
There is no pump station, construction camp or block valve station in the area.			
MAP 40: MAP HIGHLIGHTS			
• Methiye Pond in area. • Major land uses are rain-fed agriculture, pastures and meadows.			
MAP 40: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted**:* two settlements on this map will be directly impacted by the pipeline project (Taslihoyuk & Methiye). They will both have land intersected (L) by the proposed pipeline. Taslihoyuk is within 500m of the pipeline route (D). None are within 5km of a construction camp, pump station, or within 2km of a block valve station. Settlements impacted by traffic have not yet been identified. There are no settlements downstream of a river/ creek crossing. • ***Surveyed:*** three settlements (Taslihoyuk, Kizilhoyuk, Altinyayla) were surveyed in the field (S) and two settlements (Methiye and Denizyas) were surveyed by telephone (T). • ***Not on map:*** Altinyayla, Denziyas, Tuzlacayir • ***Disclosure Meeting Location:*** Taslihoyuk			
SITE SPECIFIC CHARACTERISTICS			
Taslihoyuk (L) (D) (S)	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
• ***Population**:* 700 inhabitants reside in the settlement, there are 100 households. • ***Safety:*** the settlement is situated 750m from the pipeline and 400m from the nearest house. • ***Health:*** the poor sewerage system and lack of potable water network results in poor health. • ***Project attitude:*** attitudes are generally positive, however, concern exists that agricultural fields will decrease in size due to the pipeline passing arable land, leading to loss of income. No irrigation is undertaken. • ***Land ownership & use:*** 50% of land is privately owned by inhabitants with another 40% communal land. Seasonal grazing occurs.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 40 (Map 40C) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

• ***Settlement livelihood:*** agriculture (grain), trade and transport are the main sources of livelihood. • ***Availability & skills:*** drivers and welders are available. 73% of those interviewed would accept temporary employment on the pipeline construction. • ***Accessibility:*** the settlement is 14km from Altinyayla district centre. • ***Information provision:*** 90% of the population is literate. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular. There is no alternative water source. • ***Services:*** there is an electricity supply but no sewerage or waste disposal systems, there are no health care facilities. There is a primary school. • ***Settlement problems:*** problems include conflict within the settlement that divides the community in two. There are also transport difficulties and a lack of water.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Land*** Potential complications in expropriation process.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **See Overview of Land Acquisition Process in Appendix C9.**	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **See Overview of Land Acquisition Process in Appendix C9.**

Social Impact Table 40 (Map 40C) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Kizilhoyuk (S)			
• ***Demographics:*** there are 450 inhabitants with 70 households. • ***Safety:*** the settlement is situated 2.5km from the pipeline and 2.4km from the nearest house. • ***Health:*** a poor sewerage system leads to poor health. • ***Project attitude:*** attitudes towards the project are generally positive. • ***Land ownership & use:*** 50% of land is privately owned by inhabitants, with another 30% leased by the inhabitants. There is a lack of title deeds. Seasonal grazing occurs but there is no irrigation. • ***Settlement livelihood:*** agriculture (grain, vegetables), bee keeping, construction and trade are the main sources of livelihood. • ***Accessibility:*** it is 12.2km to district centre. There is poor accessibility to the settlement in January. • ***Information provision:*** 90% of the population is literate. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular and there is no alternative water source. There is electricity supply, but no sewerage or waste disposal system. • ***Services:*** there is a primary school and a market, but no health care centre. • ***Settlement problems:*** low incomes, poor sewerage system and poor roads are all problems for the settlement. • ***Other:*** there have been requests from inhabitants that the construction company improve roads and a sewerage system for the settlement.	***Accessibility to recruitment*** Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Altinyayla (S)			
• ***Demographics:*** there are 5,600 inhabitants. • ***Safety****:* the settlement is situated 7.5km from the pipeline. • ***Project attitude:*** attitudes towards the pipeline are positive.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations	Contractor will **consult** with authorities to determine maximum acceptable time	**If irrigation water is disrupted** longer than time considered acceptable by

Social Impact Table 40 (Map 40C) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

• ***Land ownership:*** 90% of land is privately owned by inhabitants, 4% is state owned. Irrigation occurs, however, there is no seasonal grazing. • ***Settlement livelihood:*** agriculture (diverse, including sugar beet), bee keeping, transportation, trade, education and local government are the main sources of livelihood. • ***Accessibility:*** the settlement is a district centre • ***Information provision:*** 90% of the population is literate. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular. There is no alternative water source. • ***Services:*** there is a primary school, and a health care centre with a doctor and a midwife. • ***Settlement problems:*** problems include no insurance and financial problems.	of flow from spills or increase in sedimentation.	for disruption.	authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Denizyas (T)			
• ***Population****:* 2,050 inhabitants reside in the settlement. • ***Project attitude:*** according to the Muhtar, the inhabitants are generally positive towards the project. • ***Land ownership & use:*** the primary landowners are the inhabitants (80%). No seasonal grazing occurs and irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (5 households produce honey for their own consumption), fishing, hunting, transport, manufacturing, construction, trade, education and local government. • ***Accessibility:*** The settlement is accessible all year. • ***Information provision:*** 85% of the population is literate. Television and the newspaper are the best information provision tools. • ***Infrastructure:*** piped water is supplied to households. • ***Settlement problems:*** poor roads, construction problems and unemployment are the main problems for the settlement.	***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing. ***Hunting*** Temporary reduction in game due to disturbance during construction.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure. Project to **establish level of hunting** in settlements prior to construction.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full. **Significance cannot be established at this time**

Social Impact Table 40 (Map 40C) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

		Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Tuzlacayir (L) **(T)**			
• ***Demographics:*** there are 100 inhabitants with seasonal migration of 35%. • ***Safety:*** the settlement is situated 1.3km from the pipeline, the nearest house is 1.2km from the pipeline. • ***Project attitude:*** attitudes towards the pipeline are mixed. The inhabitants are concerned about the project as the natural gas pipeline affected them badly. • ***Land ownership & use:*** the primary landowners are the inhabitants (70%). No seasonal grazing occurs but irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (seven households produce honey as their main source of income) and the local	***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Irrigation***	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low. Contractor will **consult** with	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **If irrigation water is**

Social Impact Table 40 (Map 40C) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

produce honey as their main source of income),and the local government are the main sources of livelihood. • ***Accessibility:*** it is 24km to the district centre of Refahiye. The settlement is accessible all year. • ***Information provision:*** 70% of the population is literate. Television, newspaper and the Muhtar are the best information provision tools. • ***Environmental & cultural sites:*** there is a mausoleum • ***Infrastructure:*** piped water is supplied to households, however supply is irregular. A settlement fountain provides an alternative water source. • ***Settlement problems:*** the main problems are poor infrastructure, poor drinking water quality and unemployment.	Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation. ***Accessibility to recruitment*** Decreased access to recruitment process. ***Negative experience*** Possible **opposition** to project and **increased sensitivity** to any negative impacts.	authorities to determine maximum acceptable time for disruption. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. BOTAŞ is currently determining how existing concerns can be identified and resolved. **Additional meetings** may be required in these communities during construction, to ensure that any negative impacts are	**disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No residual impact expected.** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. Level of residual impact will depend on degree to which concerns are resolved prior to construction.

Social Impact Table 40 (Map 40C) (KPs 767.5 – 787.6): Uzun Plateau, Sivas/Keysari Province Border

		rapidly identified. **Construction workers to be reminded** of the importance of appropriate behaviour in daily **briefings.**	

Environmental Impact Table 41 (Maps 41A and 41B) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Truncated or severely eroded Mesic Loamy-skeletal Xerochrepts on scarps and upper slopes of rolling terrain. These are visibly eroded on the scarp north of the Zamanti River. • Mesic Typic Calcixerolls on undulating and lower slopes of rolling terrain. • Minor inclusions of fine-silty Xerofluvents near channels supporting grazed meadow and riparian vegetation.	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity; • channel alteration.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
The route continues to follow the upland stony, open, sparsely-vegetated, and largely featureless landscape. (elevations between 1,600 and 1,800m) before descending c. 70m to cross the flood plain of the Zamanti River between KPs 796.4 and 797.0. Occasional shallow, V-shaped drainage channels cut across the RoW, but these become increasingly rare as one continues south-west along the pipeline route. Riparian vegetation is limited to major streams, in particular the Zamanti River whose valley bottom comprises marshland and wet meadows rich in orchids and wildlife. Landscape sensitivity is generally low, except in this locally high quality river setting. The RoW turns gradually southward towards Pinarbasi by passing over rolling terrain (elevation 1,600 - 1,700m) with minor elements of moderately steep land. South of KP 795 it drops 80m to cross two minor reaches of the Hilmiye tributary to the Zamanti River. Wetland vegetation occupies the stream's channels and minor portions of the flood plain, but this rapidly gives way to grazed meadow. BVS-041 and BVS-042 will be located at KP 788.5 and KP 797.2,	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. May be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. This is less important here than in previous locations due to the already eroded condition of the landscape. The wet meadows and marshland either side of the Zamanti River are extremely sensitive and will show a long-term/ permanent scar unless	• Cut irrigation during construction. Clean channel on completion of work. • Attempt a high rate of fertilisation using NPK + micro-nutrients in combination with mulch such as coir fibre • Apply 'Soils' reinstatement specifications above. Measures to reduce the impact of heavy machinery will be taken when crossing the valley bottom of the Zamanti River. These will include narrowing the route to the absolute minimum; removal, storage, nurture and replacement of turfs; and the use of moveable	**MODERATE IMPACT** The wet meadows/ marshland in the Zamanti valley will inevitably experience some damage from the route's crossing, but if undertaken with care and sensitivity, this will last no more than a year or two. **MINOR IMPACTS** elsewhere as exposed marl may retain its whitish colour and show as a white line across the landscape, although this may be less conspicuous here than in previous locations due to the already eroded condition

Environmental Impact Table 41 (Maps 41A and 41B) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
respectively. BVS-041 lies within cultivated land and BVS-042 in plain steppe. Approximately 350m^2 of permanent landtake required with each BVS. New access roads will be constructed to these sites c. 60 m in length for BVS-041 and c. 45m for BVS-042	care is taken with heavy machinery. Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	equipment mats on the underlying soils to spread vehicle weight and avoid deep rutting. Construction will be undertaken at the driest time of the year (ie between July and September). There will be no storage of materials, pipe or topsoil on sensitive marshy soils.	of the landscape.
Surface Waters			
The pipeline route crosses Zamanti River, which is an important for both aquatic vegetation and fauna. River channel is irregular and meandering with a rectangular cross-section at the meander inflection point. Width of crossing is 25m and the bank-full width is between 15 and 21m, although the floodplain is c. 750m wide. Bed consists of silt and river flow is perennial of a uniform and tranquil type. Bank side vegetation comprises reeds and sedges and land use type is hay and grazing. An irrigation offtake is approximately 3.5km upstream. Water quality samples taken 170m downstream of the crossing point indicate that this is a Class IV river.	Direct disturbance to bank and bed morphology through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in already poor water quality. Potential for short -term sedimentation and turbidity. Potential impacts on downstream ecology and water abstraction for human use.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, Including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities and provide where necessary if sedimentation and turbidity persist for more than 3 days at the community.	**MINOR IMPACT** Disturbance will be short-term and limited to the immediate working area. Sedimentation of Zamanti River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Ecology			
Important Ecological Factors The Zamanti River floodplain (KP 796.4 and KP 797.0) is identified as an Ecologically Sensitive Area, (ESA 36), largely because of its fragility. It is a broad, orchid-rich, marshy grass floodplain (c. 600m in length), crossed by the pipeline route north-west of Ucpinar Settlement, growing on deep layers	Loss of wet meadow and marsh habitats containing abundant orchids.	Zamanti River floodplain will be crossed with utmost sensitivity. The crossing will be undertaken outside of the breeding season, (ie	**MODERATE IMPACTS** Short-term disturbance to globally-threatened plants within ESA 37 and locally important flora, although not

Environmental Impact Table 41 (Maps 41A and 41B) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
of soft, wet, peat-like humus-rich sediments. Although no globally or nationally-threatened plants have been located, the marsh supports many flowering plants amongst which the abundance of Bog Orchids (*Orchis palustris*) is notable. The floodplain also acts as an important stopover point for migrant waders and a breeding site for other waders and riparian species. Totals counted within 1km either side of the pipeline centreline on 16.05.2001 include – Little Egret 5; Grey Heron 3; White Stork 1; Ruddy Shelduck 2; Common Crane 2 (nationally-threatened); Black-winged Stilt 3; Lapwing 4; Redshank 4; Wood Sandpiper 42; Ruff 125; Black-headed Wagtail 21; Yellow Wagtail 1; Whinchat 3 (nationally-threatened); Sedge Warbler 10; and Icterine Warbler 1 (nationally-threatened). The protection status for these species are given in Table 5.21, Section 5. The European Pond Turtle (globally-threatened) was recorded at the Zamanti River. The protection status for this species is given in Table 5.21, Section 5. ESA 37 is identified between KP 797.8 and KP 798.4 for the globally-threatened plant species (*Campanula strigillosa*). The IUCN status for this species is given in Table 5.20, Section 5. The Zamanti River supports breeding and migratory fish species of high commercial value - brown trout (*Salmo trutta magrosligma*), breeding between December to February, and European eel (*Anguilla anguilla*), breeding from April to August and migrating between September and March.	Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods. Temporary localised disturbance to globally-threatened reptile species between May and September inclusive. The European Pond Turtle typically mates in May, with eggs (up to 10 per clutch) laid amongst the roots of waterside vegetation in June. Incubation period is dependent upon variable by temperature, but is generally in the order of 70 days. Hatchlings emerge August – September. Habitat destruction of plain steppe in ESA 37 may result in the loss of individuals from populations of globally-threatened plants. Temporary disturbance to	April to July inclusive), to minimise disturbance to breeding birds and returning autumn migrants. Heavy machinery working on the marsh will use balloon tyres or be supported on moveable equipment mats plates or similar. Vegetation will be lifted as turfs, marked, nurtured and kept wet while being stored, and replaced in sequence. In advance of construction works associated with the Zamanti River crossing, riverside vegetation will be cleared between beginning of October and end of April, ie outside of the breeding season for the European Pond Turtle. Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 37. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as	globally or nationally-threatened, within ESA 36. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACTS** only to the globally-threatened European Pond Turtle, where the specified mitigation measures identified for the seasonal sensitivity are applied during the construction period. **MINOR IMPACTS** at most for all fish species if construction

Environmental Impact Table 41 (Maps 41A and 41B) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	commercially important fish and aquatic plants providing breeding sites for these species during construction across the Zamanti River.	described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during re-instatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 37.Construction activities at river crossings will not be permitted during the breeding season of fish species that are of high commercial value or that are designated has having conservation importance. For construction activity to be permitted during the breeding season of fish species with medium commercial value, the Contractor will be required to submit specific mitigation measures to avoid impacting breeding fish to BOTAŞ for approval. Such measures might include, but not be limited to, the following: preconstruction survey results indicating that spawning	takes place during August to November inclusive. At other times of year (varying by species), impacts will generally be **MINOR** on the basis of the rigid application of water crossing mitigation measures. Where construction is undertaken during the breeding season, impacts may be **MODERATE** on highly commercially valuable migrating brown trout and European eel. Additional mitigation will be required to allow passage of fish past the works during construction. Impacts to other fish species will be **MINOR**.

Environmental Impact Table 41 (Maps 41A and 41B) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		grounds are avoided, the provision of fish passages, etc, in addition to the generic mitigation measures that are required at all river crossings.	
Archaeology and Cultural Heritage			
Hilmiye Graveyard (1st Degree Site) – a Turkmen cemetery from the Ottoman Period, located to the west of the Pipeline. This site appears to have been destroyed. * This site has not yet been registered by the MoC and is provisionally assigned this classification. The site has been proposed for registration by the regional preservation council The following have also been proposed for registration: (i) Hacitim Hill; (ii) Roman Bridge and Road	Potential for site to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	The pipeline has been re-routed to avoid this site. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Kayseri Socio-Economic Overview

Demographics:
Kayseri is the third largest pipeline province (974,000 inhabitants) with 64% of its population living in urban areas (the second most urbanised of the pipeline provinces). The average household size is six, mirroring the survey average and reflecting a traditional, patri-local* family structure and a preference for more children. The province experiences the third highest density levels (56 inhabitants per km2). Some out-migration is experienced in both rural and urban areas. In some settlements, inhabitants migrate to Sariz, the district centre to enable access to secondary schools for their children (particularly in winter). Although there has been some out-migration, the culturally 'conservative' structure of some settlements (local residents are generally of the Avşar Turkish tribe) and relatively more abundant agricultural assets has worked against this trend. The findings suggest that historically there have been conflicts between the local residents and between different groups in the region. Until recently, intermarriage between settlements was not experienced and women were rarely exposed to 'outsiders'. This more conservative attitude was evident in the reluctance to allow females to attend consultation meetings although this was not always the case, and in one settlement, young single educated women requested work on the construction camps.

Land:
Private ownership, followed by communal ownership is most common. The province exhibits high levels of inequality and land polarisation. Local residents generally lack title deeds and instead, families have only the right of possession.

Livelihoods:
Local residents in Kayseri are relatively wealthier than in other parts of Inner Anatolia. However, non-protective policies of the 1980s had a negative effect on these settlements. Economies are based on agriculture and animal husbandry.

Infrastructure & Services:
Infrastructure is inadequate and the majority of local residents do not have adequate drinking water or sewerage systems. There is insufficient water for home use, irrigation and animal husbandry. Almost all settlements have access to grid electricity, but lack proper energy for heating. Literacy amongst surveyed respondents is quite high, with the exception of elderly women. Almost 70% have attended primary or secondary school and 3% have attended university. Some settlements have primary schools whereas in others, children use free transportation (provided by the State) to travel to the closest settlement/ district centre to obtain primary education. However, in winter students face problems, notably because roads are often blocked. There are no medical centres with the exception of one settlement. Instead, residents use mobile nursing services and facilities in the district centres. This situation is deemed insufficient in emergencies. There are no other social services within the province, with the exception of transportation.

Key Problems:
Water shortages, which in some cases contribute to conflict, were rated as the predominant settlement-level problem. Other significant problems raised by respondents were high agricultural product prices (eg for diesel oil, fertilizer), reduced agricultural profit, and that unemployment was particularly high amongst young adults.

Project Attitude:
Inhabitants have had experience of the NGP Project. Avsar local residents suggested that attention should be paid to these more conservative settlements during construction.

Source: Household and Settlement Survey (2001)

Social Impact Table 41 (Maps 41C) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

MAP 41: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There are two block valves.

MAP 41: MAP HIGHLIGHTS

- Major land uses: rain-fed agriculture, pastures and meadows.
- Pipeline passes to the west of Hacitim Hill, ceramic shards from the Hittite period were observed.
- One creek and one river bisect the pipeline.
- Seasonal migration of 10% occurs in all settlements.
- Main economic activity is agriculture.
- Bee keeping, fishing and hunting activities undertaken in area.

MAP 41: IMPACTED AND SURVEYED SETTLEMENTS

- ***Impacted:*** Two settlements on this map will be directly impacted by the pipeline project (Ucpinar and Hilmiye). Both have land intersected by the proposed pipeline (L); none are within 5km of a pump station; one (Hilmiye) is within 500m of the pipeline route (D); and one (Ucpinar) is within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. Two settlements are within 2km upstream of a river/creek, Hilmiye is upstream of the Hilmiye creek, and Ucpinar is upstream of the Zamanti River.

- ***Surveyed:*** Two settlements were surveyed by telephone (T).
- ***Not Surveyed:*** Viransehir.
- ***Disclosure Meeting Location:*** Hilmiye

SITE SPECIFIC CHARACTERISTICS	ADDDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Ucpinar (L) (D) (B) (T)			
• ***Demographics:*** 70 inhabitants, with a seasonal migration of 10%. • ***Safety:*** the pipeline is 1km from the centre of the settlement and 600m from the nearest house. • ***Project attitude:*** generally positive, with high awareness. • ***Land ownership & use:*** 90% of land is privately owned by the local residents. Irrigation is undertaken and seasonal grazing occurs. • ***Settlement livelihood:*** agriculture and bee keeping (four households for own consumption) are the mains sources of livelihood. 60% of respondents are family labourers and 40% are farmers.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 41 (Maps 41C) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

respondents are family labourers and 40% are farmers. • ***Accessibility:*** the settlement is 39 km from the district centre (Pinarbaşi). It is accessible all year all year round. • ***Information provision:*** 100% of the population is literate. Best information provision techniques are TV, newspaper and via the Muhtar. • ***Environmental & cultural sites:*** plateau. • ***Settlement problems***: low income.	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage will be compensated for.**
	Construction hazards: animals Trench poses safety hazard for livestock	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.
	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover)	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 41 (Maps 41C) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

	essential for nectar production. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Block Valve Station*** See Environmental Impact Tables and the Overview of the Land Acquisition Process in Appendix C9	**Community liaison meetings:** issue to be discussed at meetings before and during construction. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
SITE SPECIFIC CHARACTERISTICS	**ADDDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Hilmiye (L) (D) (T)			
• ***Demographics****:* 248 inhabitants with seasonal migration of 10%. • ***Safety:*** the pipeline is 800m from the centre of the settlement and 450m from the nearest house.	***Construction hazards: humans*** Working areas pose safety	**Road safety training** will be held in schools prior to	**Continued attention** to mitigation measures will be

Social Impact Table 41 (Maps 41C) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

450m from the nearest house. • ***Project attitude:*** generally positive with high awareness levels. • ***Land ownership & use:*** local residents privately own 80% of land. Diverse grazing occurs. There is no irrigation. • ***Settlement livelihood:*** agriculture, bee keeping (one household for own consumption), fishing (30 households for own consumption) hunting, construction and trade are the main sources of livelihood. 50% of respondents are family labourers and 50% are farmers. • ***Accessibility:*** the settlement is 32 km from the district centre (Pinarbaşi). The roads are of poor quality but are accessible all year round. • ***Information provision:*** 90% of the population is literate. The best information provision source is TV. • ***Settlement problems***: poor roads and inadequate childcare.	hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Bees*** Disturbance of any stationary hives located within 300m of the route.	construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives	critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage to be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee

Social Impact Table 41 (Maps 41C) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

		must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Hunting Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	**Significance cannot be established at this time.**
	Accessibility of Information Sectors of the population	**Communication with settlement** must take into account settlement	**Any change can highlight and exacerbate existing divisions** in communities.

Social Impact Table 41 (Maps 41C) (KPs 787.6 – 805.8): Uzun Plateau, Kayseri Province

	may not have access to project related information on employment opportunities, potential disruption to utilities etc.	characteristics to ensure equal access to information for all residents.	Mitigation measures will keep this to a minimum.

Environmental Impact Table 42 (Maps 42A and 42B) (KPs 805.8 – 819.7): Parallel to the Zamanti River to South-East of Altiesik Settlement, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils types from the previous section continue in this section of the route: • Truncated or severely eroded Mesic Loamy-skeletal Xerochrepts on scarps and upper slopes of rolling terrain. • Mesic Typic Calcixerolls on undulating and lower slopes of rolling terrain. • Minor inclusions of Fine-silty Xerofluvents near channels supporting grazed meadow and riparian vegetation.	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity; • channel alteration.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	**MINOR IMPACT** Soil productivity losses are predicted to last less than 3 months after construction is completed. Furthermore, soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
The route continues south across stonier rolling plains with sparse steppe vegetation interspersed with non-intensive cereal fields. Electricity cables cross the route at KP 804. Bare slopes are an important feature of the landscape, with rainfed cereals occupying valley bottoms. Minor areas of low-density forest occupy some slopes. The uniform landscape, with few areas of distinction will be relatively resilient to change.	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. This may be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. However, given the existing character of the landscape these changes will be of moderate significance condition of the landscape.	Apply 'Soils' reinstatement specifications above. Attempt a high rate of fertilisation in combination with mulch such as coir fibre.	**MINOR IMPACT** Landscape is considered to be of low sensitivity and generally resilient to change.
Arhchaeology and Cultural heritage			
(i) Roman Bridge - 1st Degree site* (ii) Hacitimpinari ridge - 1st Degree;* (iii) Roman bridge - 1st Degree;*

MAP 42: PROJECT INFORMATION

There are no pump stations, construction camps or block valve stations in the area.

MAP 42: MAP HIGHLIGHTS

- Major land use is rain fed agriculture, pastures and meadows (but no animal breeding).
- There is an archaeological site (Roman bridge) 600m west of pipeline.

MAP 42: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted****:* four settlements on this map will be directly impacted by the pipeline project. They all have land intersected by the proposed pipeline (L) (Tasoluk, Alamescit, Asagi Kizilcev, Altiesek). None are within 5km of a pump station, or within 2km of a block valve station, and none are within 500m of the pipeline route. Settlements impacted by traffic have not yet been identified. No settlements are downstream of a river.

- ***Surveyed****:* one settlement (Tasoluk) was surveyed in the field (S) and all four settlements were surveyed by telephone (T).

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Tasoluk (L) **(S) (T)**			
• ***Demographics:*** 85 inhabitants with 16 households and seasonal migration of 50%. • ***Safety:*** the pipeline is 2.6km from the centre of the settlement and 2.4km from the nearest residence. • ***Project attitude:*** generally positive with high awareness, although it will be important that passage for tractors across the pipeline construction area is possible, and that dedicated animal crossing points are established. Women with high school education are eager for any opportunities to work at the construction camps. The majority of respondents would welcome a construction camp. 36% of households would benefit from direct employment, 27% expressed concern of noise/dust and 18% expressed concern about road damage/traffic. • ***Land ownership & use:*** 90% of land is owned by the local residents. Grain is cultivated and there is livestock breeding. Seasonal grazing occurs in April & May and September &	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Drinking water for animals*** Increased sediment up to 1km downstream of river crossing. ***Accessibility of information*** Sectors of the population may not have access to project related	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. Settlement to be advised to water their animals upstream or more than 1km downstream. **Communication with settlement** must take into account settlement	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No residual impact.** **Any change can highlight and exacerbate existing divisions** in communities.

Social Impact Table 42 (Maps 42C) (KPs 805.1 – 819.7):
Parallel to the Zamanti River to South-East of Altiesik Settlement, Kayseri Province

October. There is no irrigation. Concern over the potential impact of dust associated with construction on cultivated land. • ***Settlement livelihood:*** agriculture and tourism are the main sources of livelihood. • ***Availability & skills:*** tractor drivers and vehicle drivers are available. 73% of respondents would accept a temporary job. • ***Accessibility:*** the settlement is 6km from the district centre. Roads are of poor quality and are not accessible during February and March. • ***Information provision:*** 100% of the population is literate. Best local information provision sources are TV, the newspaper, family and via the Muhtar. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. There is electricity supply and telephone systems but no sewerage or waste disposal system • ***Services:*** there is no primary school and no health care centre, however, there is access to a travelling health care team. • ***Settlement problems***: unemployment, low income, poor roads, no irrigation canals and supply of water for cattle is inadequate. • ***Other***: daily use of Zamanli stream 5km from the settlement for animal drinking water. Note: this stream is the settlement's only water source for animals and crosses the pipeline.	information on employment opportunities, potential disruption to utilities etc ***Sensitive crops (cotton)*** Dust may affect yields of crops essential for subsistence or commercial livelihoods. ***Accessibility to recruitment*** Decreased access to recruitment process	characteristics to ensure equal access to information for all residents. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	Mitigation measures will keep this to a minimum. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Alamescit (L) **(T)**			
• ***Demographics****:* 50 inhabitants with seasonal migration of 90%. • ***Safety:*** the pipeline is 3.5km from the centre of the settlement and 2.4km from the nearest residence. • ***Project attitude:*** generally positive with good awareness of the project. The majority of respondents would welcome a construction camp. • ***Land ownership & use:*** 100% of land is owned by the local residents. Predominantly subsistence agriculture is undertaken.	***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. .	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 42 (Maps 42C) (KPs 805.1 – 819.7):
Parallel to the Zamanti River to South-East of Altiesik Settlement, Kayseri Province

There is no irrigation and no seasonal grazing. • ***Settlement livelihood:*** agriculture is the main source of livelihood and 100% of respondents are family labourers. • ***Accessibility:*** the settlement is 21km from Pinarbasi district centre. Poor roads, however the settlement is accessible all year. • ***Information provision:*** Turkish & Cerkezish is spoken. 100% of the population is literate. Best information provision tools are TV, radio, friends & family, and via the Muhtar. • ***Infrastructure:*** piped water is supplied to households. There is a regular supply, no alternative water source • ***Settlement problems***: inadequate access to water, unemployment and poor roads.	***Accessibility to recruitment*** Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Asagi Kizilcev (L) (T)			
• ***Demographics****:* 50 inhabitants with seasonal migration of 20%. • ***Safety:*** the pipeline is 2.4km from the centre of the settlement and 2.2km from the nearest residence. • ***Project attitude:*** no hostility and good awareness. A construction camp would be welcomed. • ***Land ownership & use:*** 50% of land is privately owned by the local residents. Seasonal grazing occurs. Irrigation occurs. • ***Settlement livelihood:*** agriculture, bee keeping (two households for own consumption), manufacturing, construction, transport and trade are the main sources of livelihood. • ***Availability & skills:*** previous experience of a bridge construction project • ***Accessibility:*** 18km to Pinarbasi district centre. Poor quality roads. Accessible throughout the year. • ***Information provision:*** Turkish & Cerkezish is spoken. 100% of the population is literate. Best information provision tools are TV, radio, press, family, friends, and via the Muhtar.	***Construction hazards: animals*** Trench poses safety hazard for livestock.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.

Social Impact Table 42 (Maps 42C) (KPs 805.1 – 819.7):
Parallel to the Zamanti River to South-East of Altiesik Settlement, Kayseri Province

• ***Environmental & cultural sites:*** graveyard. • ***Infrastructure:*** piped water is supplied to households however supply is irregular. The settlement fountain provides an alternative water source • ***Settlement problems***: inadequate access to water, infrastructure problems and poor roads.		sources of water to be provided.	
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Accessibility to recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Mitigation measures will keep this to a minimum. **No residual impact expected** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Environmental Impact Table 43 (Maps 43A and 43B) (KPs 819.7 – 834.3): North of Asagi Borandere Settlement to East of Karagoz Creek, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Typic Calcixerolls on undulating lands. • Loamy-skeletal Xerochrepts on slopes. • Mesic Typic Xerofluvents in floodplains.	Main potential impacts: • soil erosion. • sediment yield. • soil productivity. • channel alteration.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.
Landscape and Visual			
The route continues over stony rolling plains with sparse steppe vegetation interspersed with non-intensive cereal fields. It crosses a major highway near KP 813 and then in quick succession, the Kirkpinar and Asmacasuyu Creeks. This 2km section presents a more varied landscape of heavily cultivated valleys (with hay meadows, cereals and pasture) and settlement (including the settlements of Asagi Borandere and Yukari Borandere, which lie close to the route). The lightly-forested Tahtali Mountains form an ever-more prominent backdrop. Landscape values are low. BVS-043 will be located at KP 826.5 within cultivated land. Approximately 350m^2 of permanent landtake will be required. A new access road will be constructed to the site of c. 20m^2 in length.	Formation of conspicuous whitish line across landscape where pale-coloured marl is exposed. This may be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. Most prominent in valley bottoms. Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	Attempt a high rate of fertilisation in combination with mulch such as coir fibre.	**MINOR IMPACT** Landscape considered to be of low sensitivity and generally resilient to change.
Noise			
Yukari Borandere settlement is located c. 212m from the centreline of the	Short-term noise impacts are	The following mitigation measures	**MINOR IMPACT**

Environmental Impact Table 43 (Maps 43A and 43B) (KPs 819.7 – 834.3): North of Asagi Borandere Settlement to East of Karagoz Creek, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Pipeline.	expected to occur at Yukari Borandere during soil stripping activities.	will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings and where possible, utilising existing screening, including that arising from the stockpiling of materials. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	Short-term noise impacts are expected to occur during soil stripping. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.

Social Impact Table 43 (Maps 43C) (KPs 819.7 – 834.3):
North of Asagi Borandere Settlement to East of Karagoz Creek, Kayseri Province

MAP 43: PROJECT INFORMATION			
There are no pump stations or construction camps in the area. There is one block valve station.			
MAP 43: MAP HIGHLIGHTS			
• Rain fed agriculture is the main land use. There are also areas of pasture and irrigated agriculture, and low density forests. • The pipeline crosses the Kirkpinar river, the Asmacasuyu river and a national highway.			
MAP 43: SURVEYED AND IMPACTED SETTLEMENTS			
• ***Impacted:*** Two settlements on this map will be directly impacted by the pipeline project (Asagi Borandere, Yukari Borandere). They both have land intersected by the proposed pipeline (L) and both are within 500m of the pipeline route (D). No settlements are within 5km of a pump station. One settlement (Yukari Borandere) is within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. One settlement (Asagi Borandere) is downstream of the pipeline on the Asmacasuyu River. • ***Surveyed:*** Two settlements (Asagi Borandere, Yukari Borandere) were surveyed by telephone (T). • ***Disclosure Meeting Location:*** Yukari Borandere			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Asagi Borandere (L) (D) (R) (T)			
• ***Demographics:*** 1,208 inhabitants with no seasonal migration. • ***Safety:*** the pipeline is 700m from the centre of the settlement and 500m from the nearest residence. • ***Project attitude:*** generally positive with no major concerns. In addition, the majority of respondents would welcome a construction camp. • ***Land ownership & use*****:** 90% of land is privately owned by the local residents. Irrigation is undertaken. There is no seasonal grazing. • ***Settlement livelihood:*** agriculture, bee keeping (one household produces honey for own consumption) and forestry are the main sources of livelihood. 75% of respondents are family labourers. • ***Availability & Skills:*** no previous experience. • ***Accessibility:*** 17.5km to the district centre (Pinarbaşi). The settlement is accessible all year.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 43 (Maps 43C) (KPs 819.7 – 834.3):
North of Asagi Borandere Settlement to East of Karagoz Creek, Kayseri Province

settlement is accessible all year. • ***Information provision:*** 75% of the population is literate. The best information provision tool is TV. • ***Infrastructure:*** piped water is supplied to households however supply is irregular. An artesian well is an alternative water source. • ***Settlement problems***: inadequate access to water and inadequate health care.	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage will be compensated for.**
		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Forestry Loss of a resource used by settlements. Increased expenditure on other fuel sources.	If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of	**Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.

Social Impact Table 43 (Maps 43C) (KPs 819.7 – 834.3): North of Asagi Borandere Settlement to East of Karagoz Creek, Kayseri Province

		compensation will be facilitated by the Projects complaints procedure.	
	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Access to information: Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 43 (Maps 43C) (KPs 819.7 – 834.3):
North of Asagi Borandere Settlement to East of Karagoz Creek, Kayseri Province

		include emphasising oral communication where literacy is low.	
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Yukari Borandere (L) (D) (B) (T)			
• ***Demographics:*** 170 inhabitants with 10% seasonal migration. • ***Safety:*** the pipeline is 450m from the pipeline and 200m from the nearest residence. • ***Project attitude:*** generally positive with no major concerns. A construction camp would be welcome. • ***Land ownership & use*****:** 90% of land is privately owned by local residents. Irrigation activities are undertaken. There is no seasonal grazing of livestock. • ***Settlement livelihood:*** agriculture, bee keeping (six households produce honey for their own consumption), forestry, fishing (by one household, as one of many income sources) and trade are the main sources of livelihood. 60% of respondents are family labourers. • ***Accessibility:*** 21km to the district centre (Pinarbaşi). The settlement is accessible all year. • ***Information provision:*** 95% of the population is literate. The best information provision tools are TV and via the Muhtar. • ***Infrastructure:*** piped water is supplied to households however supply is irregular. There is no alternative water source. • ***Settlement problems:*** unemployment, delays in payment from selling agricultural products and forest fields.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Bees*** Disturbance of any stationary hives located within 300m of the route.	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee

Social Impact Table 43 (Maps 43C) (KPs 819.7 – 834.3): North of Asagi Borandere Settlement to East of Karagoz Creek, Kayseri Province

		must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Forest Loss of a resource used by settlements. Increased expenditure on other fuel sources.	If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure.	**Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow,

Social Impact Table 43 (Maps 43C) (KPs 819.7 – 834.3):
North of Asagi Borandere Settlement to East of Karagoz Creek, Kayseri Province

	in sedimentation. ***Access to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Block Valve Station*** See Environmental Impact Tables and Overview of the Land Acquisition Process in Appendix C9	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Environmental Impact Table 44 (Maps 44A and 44B) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Loamy-skeletal shallow Xerochrepts on slopes. • Channel sands, gravel, cobbles and boulders.	Main potential impacts: • soil erosion; • sediment yield; • soil productivity; • channel alteration.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings (erect a geo-fabric silt-fence type barrier between Kevenli Creek and construction).	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.
Landscape and Visual			
Following the extensive plateau land to the north, the route now enters a more diverse terrain. The route enters the very narrow, steep-sided, rocky, Kirkgecit Valley and follows it for some 4km. The valley's, slopes are lined with juniper scrub and a small tree-lined river meanders through meadows. Mountainous terrain rises above it. The steepness of the valley, the intimacy of the scenery, and the large contrast between the valley floor and the harsher slopes provide landscape interest. Landscape sensitivity is moderate. At the southern end, the valley opens out into flower-rich lush meadows with a crystal clear river where landscape quality is high. The route climbs over a ridge at 1,960m asl from where striking views look southwards towards the snow-capped peaks of the Taurus mountains. The route then begins to descend through this undulating steppe terrain whose landform and sparse vegetation will be relatively resilient to the BTC Pipeline.	Intimacy of landscapes within the valley very vulnerable to impact since construction activities will be magnified by condensed views. Minor loss of trees and bushes. Wet meadows at southern entrance to valley particularly susceptible to damage. Thin soils on high level ridge may cause difficulties for reinstatement. Potential for short-term visual impact during construction for villagers in Yukan Borandere	• The pipeline has been re-routed away from the Kirkgecit Valley and now follows a ridgeline for about 6km, west of the current alignment, through sparse forests of juniper and oak and montane steppe habitat. • Reinstatement of pipeline route and re-establishment of any woodland vegetation that is lost (specific mitigation to be developed following site survey prior to the commencement of construction). • Particular attention will be paid to the control of dust, noise and	**MODERATE TO MINOR IMPACT** Residual impacts cannot be determined precisely at this stage since the re-route has not been subject to detailed survey. Upland habitat may be reluctant to re-establish quickly, but the re-route will affect a less sensitive landscape and predicted impacts are correspondingly reduced. **MINOR IMPACT** Given the relatively small size

Environmental Impact Table 44 (Maps 44A and 44B) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
BVS-044 will be located at KP 849.3 within cultivated land. Approximately 350m^2 of permanent landtake required. A new access road will be constructed of c. 20m in length. Yukan Borandere settlement lies c. 210m from the site.	settlement during construction of BVS-044.	to the control of dust, noise and traffic during construction at BVS-044.	of the block valve station and the temporary nature of construction activities, visual impacts are anticipated to be minor, subject to implementation of the specified mitigation measures.
Ecology			
Important Ecological Factors ESA 38 previously c. 10.5km of the previous route. This ESA is identified between KP 841.9 and KP 847.6 for eighteen globally-threatened plant species occur between KPs 833.9 – 846.7 (*Asyneuma linifolium spp. eximium, Phryna ortegioides, Silene caryophylloides spp. stentoria, Cerastium saccardoanum, Minuartia rimarum var. multiflora, Minuartia dianthifolia spp. cataonica, Senecio jurineifolius, Centaurea derderiifolia, Doronicum haussknechtii, Isatis huber-morathii, Salvia eriophora, Isatis aucheri, Crocus kotschyanus spp. cappadocicus, Thlaspi densiflorum, Graellsia davisiana, Muscari microstomum, Hyacinthella acutiloba* and *Fritillaria aurea*). This is the most concentrated area of globally-threatened plants along the entire route. In addition, another four globally-threatened plants (*Achillea goniocephala, Astragalus sparsipilis, Astragalus cymbibracteatus* and *Ferula longipedunculata*) are found adjacent to the route corridor parallel to ESA 38. The IUCN status for these species are given in Table 5.20, Section 5. Grey Wolf was recorded to the north-west of the route at KPs 835. This species is not globally-threatened and has no protection in Turkey, although it is protected under CITES, the Bern Convention and the EU Habitats Directive. Surveys were undertaken in mid-2002 to assess the ecology of the re-route between KP835 and KP 842. The surveys identified ESA 54 (KP 836.02-841.92) for the presence of a range of endemic species including two globally threatened endemic plant species – *Allium tauricola* and *Pimpinella anisetum*	Habitat destruction of forest and montane steppe may result in the loss of individuals from populations of globally-threatened plants. Potential for minor temporary impacts to wolves as hunting of this species is permitted in Turkey. However, this species is nomadic during spring and summer, which are the optimum months during which pipeline construction is likely to occur.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 38 and ESA 54. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for wolves with the application of the specified mitigation measures.

Environmental Impact Table 44 (Maps 44A and 44B) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
anisetum.		until replacement during reinstatement of the RoW. In areas where the presence of wolves has been confirmed, education of workers to be alert and aware of the potential for interactions will include refuse management on sites (particularly where construction camps are located). Furthermore, workers must not wander alone in areas where wolves may be present, especially at night. The hunting of wolves or any other wildlife by the BTC Project personnel or contractors will be strictly forbidden and rigorously enforced.	
Noise			
Kirkgecit settlement is located c. 65m from the centreline of the Pipeline. Blasting may also be required in this area of the pipeline route.	Short-term noise impacts are expected to occur at Kirkgecit during soil stripping, welding and lowering, backfilling, bending and trenching activities. Blasting works are also expected to give rise to noise and vibration impacts at Kirkgecit.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings;	**MODERATE IMPACT** Due to the proximity of Kirkgecit to the Pipeline, noise impacts are expected to occur during soil stripping, welding/lowering, backfilling; bending/trenching activities and during blasting. Although noise and vibration from blasting may give rise to annoyance to residents, it is unlikely to cause structural damage to buildings.

Environmental Impact Table 44 (Maps 44A and 44B) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	The Contractor will carry out detailed noise and vibration predictions once the specific blasting methods have been developed. The proposed method of working and mitigation measures will be agreed with the relevant authorities in advance of works taking place. Residents will also be notified in advance of works involving blasting.
Archaeology and Cultural Heritage			
Salderesi Area is a 1st Degree Site*, which comprises two previously identified archaeological sites (Mecit Hill and Salderesi settlement). This site consists of a low settlement and mound and the ruined remains of a settlement on the north-east slope of the hill. Ceramic shards and the remains of an ancient settlement were observed during route narrowing investigations. Alafli Tower is a 1st Degree.site* Settlement on NE slope of Mecit Hill is a 1st Degree site* * These sites have not yet been registered by the MoC and is provisionally assigned this classification. Salderesi area is Proposed for Registration The following areas are also proposed for registration: (i) Kirkgecit mound; (ii) Kirkgecit caravanserai; (iii) Tumulus (Kirkgecit village)	Potential for the site to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	The pipeline has been re-routed to avoid the Salderesi Area. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Social Impact Table 44 (Map 44C) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

MAP 44: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There is one block valve station.

MAP 44: MAP HIGHLIGHTS

- Major land use is pasture. There are also some small areas of non-agricultural land and rain-fed agriculture.
- There are four archaeologically important sites in the area.
- The pipeline crosses the Kevenli river.

MAP 44: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** Four settlements on this map will be directly impacted by the pipeline project (Kirkgecit, Orensehir, Karapinar, Tekneli). They all have land intersected by the proposed pipeline (L). Two (Kirkgecit and Tekneli) are within 500m of the pipeline route (D) and none are within 5km of a pump station. Two (Koyukoy and Tekneli) are within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. No settlements are downstream of a river crossing.

- ***Surveyed:*** One settlement was surveyed in the field (Tekneli) (S) and three settlements were surveyed by telephone (T).
- ***Not surveyed:*** Kevenli, Kotukoy and Tumulus.
- ***Not on map:*** Orensehir

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Kirkgecit (L) (D) (T)			
• ***Demographics:*** 270 inhabitants with 80% seasonal migration. • ***Safety:*** the pipeline is 350m from the centre of the settlement and 65m from the nearest residence. • ***Land ownership & use*****:** 60% of land is communal. Seasonal grazing occurs. There is no irrigation. • ***Settlement livelihood:*** agriculture, hunting and trade are the main sources of livelihood. 45% of respondents are family labourers. • ***Availability & skills:*** welders, lathe operators and levellers are present in the settlement. • ***Accessibility:*** 16km to the district centre (Pinarbaşi). The settlement is accessible throughout the year.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 44 (Map 44C) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

• ***Information provision:*** 90% of the population is literate. The best information provision tool is TV. • ***Environmental & cultural site:*** historical remnant. • ***Infrastructure:*** piped water is supplied to households however supply is irregular. A local spring and a settlement fountain provide alternative water sources. • ***Settlement problems***: poor roads, infrastructure problems and unemployment		construction work.	
	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage will be compensated for.**
	Construction hazards: animals Trench poses safety hazard for livestock	**Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock.	**High likelihood of a few accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.
	Land Potential complications in expropriation process.	**See Overview of the Land Acquisition Process in Appendix C9**	**See Overview of the Land Acquisition Process in Appendix C9**
		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.

Social Impact Table 44 (Map 44C) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

	Hunting Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	**Significance cannot be established at this time**
	Accessibility to recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Orensehir (L) (T)			
• ***Demographics:*** 178 inhabitants with 1% seasonal migration. ***Safety:*** 3.6km to pipeline. • ***Land ownership & use*****:** 90% of land is privately owned by the local residents. Irrigation activities are undertaken. There is no grazing. • ***Settlement livelihood:*** agriculture, bee keeping (7 households produce honey for own consumption), fishing (30 households fish, it is one of many sources of income), construction, trade and education are the main sources of livelihood. 5% of respondents are in regular paid jobs and 70% are family labourers. • ***Accessibility:*** 38km to district centre. The settlement is accessible throughout the year.	***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats **if** within 2 km downstream of a river crossing.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.

Social Impact Table 44 (Map 44C) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

throughout the year. • ***Information provision:*** 100% of the population is literate. The best information provision tools are TV and the newspaper. • ***Environmental & cultural sites:*** castle. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. • ***Settlement problems***: insufficient food.	***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	complaints procedure. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Access to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. Inhabitants or workers to translate as necessary.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Karapinar (L) (T)			
• ***Demographics:*** 807 inhabitants with 60% seasonal migration. • ***Safety:*** the pipeline is 1.7km from the centre of the settlement and 1.5km from the nearest residence.	***Irrigation*** Potential loss of flow from planned/ accidental	Contractor will **consult** with authorities to determine	**If irrigation water is disrupted** longer than time

Social Impact Table 44 (Map 44C) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

1.5km from the nearest residence. • ***Project attitude:*** according to the Muhtar, the inhabitants are generally positive with no major concerns. • ***Land ownership & use:*** 95% of land is privately owned by local residents. Irrigation activities are undertaken. There is no seasonal grazing. • ***Settlement livelihood:*** agriculture, bee keeping (one household produces honey for their own consumption) and construction are the main sources of livelihood. 100% of respondents are family labourers. • ***Accessibility:*** 18km to district centre. The settlement is accessible throughout the year. • ***Information provision:*** all local residents speak Turkish. 80% of the population is literate. The best information provision tool is TV. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular. A local spring provides an alternative water source • ***Settlement problems***: poor roads and inadequate access to water.	disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to recruitment*** Decreased access to recruitment process. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	maximum acceptable time for disruption. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. Social Impact Table 44 (Map 44C) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Tekneli (L) (D) (B) (S)			
• ***Demographics:*** 2,500 inhabitants with 287 households and seasonal migration of 60%. This is due to winter work in Adana. • ***Safety:*** the pipeline is 450m from the centre of the settlement and 100m from the nearest residence. • ***Disputes:*** there is some hostility and an inclination towards violence in the settlement among three dominant families. Women were not allowed to participate in the meeting to discuss the pipeline. • ***Project Attitude:*** mixed. There is concern regarding security measures and concern among the local residents about risk of explosion and sabotage of the pipeline. In addition, the pipeline route passes through arable land. 31% of households perceive benefits from direct employment, 15% perceive benefit from land compensation, 54% of households expressed concerns, 31% regarding noise/dust and 23% regarding road damage/traffic. • ***Land ownership & use*:** 90% of land is privately owned by local residents and 10% is share-cropped. There are no title deeds. Seasonal grazing of a diverse range of livestock occurs in spring, summer, autumn and in December. Irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture (sugar beet, clover, wheat, potato, barley, apples, pear); animal breeding (1,000 cattle and 6,000 sheep); bee keeping (two/three households), carpet weaving; mining; transport and trade are the main sources of income. 20% of the population has been unemployed for longer than a year, 40% are family labourers and 20% are seasonal labourers. Wealthy local residents undertake wet agriculture, have their own tractors and have irrigation canals. Poorer local residents tend to migrate to Adana in the winter to work. • ***Availability & skills:*** local residents have previous pipeline experience. The following construction skills are available: construction workers, moulders, stone, masons, turner, head of construction site, security personnel, lathe men, repairs men, tree	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Bees*** Disturbance of any stationary hives located within 300m of the route.	**Road safety training in** schools and for wider community prior to construction. **Community liaison meetings** prior to construction to include safety. **Community liaison meetings** during and immediately following construction to identify any land that has been affected. Consider erecting protective barrier fencing. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owners of need to move hives to a position at least 300m from the route. If moved during the productive season,	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from awareness raising. **Additional damage to be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried

Social Impact Table 44 (Map 44C) (KPs 834.3 – 850.2): Kirkgecit Valley, Kayseri Province

construction site, security personnel, lathe men, repairs men, tree cutting, wall masters and welders. 85% of respondents would accept a temporary job. • ***Accessibility:*** 12km to Sariz district centre. The settlement is accessible throughout the year except during January and February due to heavy snow fall. • ***Information provision:*** 60% of the population is literate. TV is the best information provision tool. • ***Infrastructure:*** piped water is supplied to households, however supply is irregular. There is no alternative water source. There is electricity supply and a sewerage system, but no waste disposal system. • ***Services:*** there is a primary school with 25 students. The health centre is not staffed; instead the local residents have access to a travelling health team including a midwife and doctor. Traditional health activities are also undertaken. • ***Settlement problems***: education, income, inadequate access to water, unemployment and emigration of educated population. Hostility amongst families.		stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Coarse-loamy to Coarse-silty Xerorthents on alluvial plains. • Mesic Fine-loamy to Loamy-skeletal Xerochrepts on sloping lands, these are probably skeletal on moderately steep and steeper lands.	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity. Other potential impacts include: • channel alteration; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Reforestation.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
The route descends to the richer agricultural lands around Sariz, proceeding along the western side of the Sariz River valley. Initially shallow soils become gradually deeper as the pipeline route passes southward and coarse grasses and sparse shrubs give way to rain-fed cereals and woodlands. Scattered trees and bushes line the small creeks flowing down to the main river, all framed by rounded mountains with exposed strata. Landscapes vary from low to moderate sensitivity. The route passes in close proximity to many settlements and, near KP 855, the main highway.	Short-term construction modifications of landscape, although highly visible during construction.	Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** If reinstatement successful, impacts will be restricted to short-term.
Ecology			
ESA 55 (KP 862.09 – 862.67) is identified for the presence of *Pimpinella anisetum*, an endemic planted listed by the IUCN as globally-threatened, which has been recorded at the edge of cultivated fields and within fallow areas.	Destruction of habitat peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 55. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same	**MINOR IMPACTS** Short to medium-term disturbance to internationally important flora and supporting habitats. Mitigation measures will minimise losses but as the globally-threatened species is a ruderal, disturbance effects are likely to be short term

Environmental Impact Table 45 (Maps 45A and 45B) (KPs 850.2 – 867.3): Teknell Settlement to Altinsogut Settlement, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW.	are likely to be short term.
Archaeology and Cultural Heritage			
The settlement mound/tumulus of Killiktepe (1st Degree Site*) is located within the 100m Corridor. There are no architectural remains on the surface of the site, although there are ceramic shards dating back to various periods (Late Calcolithic, Early and Middle Bronze Ages, Hellenistic Roman and Middle Ages). Field surveys undertaken have not been able to determine whether this site is a settlement mound or tumulus. * This site has not yet been registered by the MoC and is provisionally assigned this classification. The following have been proposed for registration by the regional preservation council: (i) Gedik area; (ii) Kocakayanin Boynu; (iii) Kocakaya; (iv) Kizilburun Hill; (v)Yunaktasi Area; (vi) Eskihamam Area; (vii) Mezarliktepe Mound	Potential for site to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	Killiktepe will be delineated to avoid accidental damage during construction and fenced throughout the construction period. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Assuming Killiktepe is fenced, impacts will be limited to the temporary disturbance to the site setting and peripheral features.

Social Impact Table 45 (Map 45C) (KPs 850.2 – 867.3): Teknell Settlement to Altinsogut Settlement, Kayseri Province

MAP 45: PROJECT INFORMATION

There are no pump stations, construction camps or block valve stations in the area.

MAP 45: MAP HIGHLIGHTS

- Main land use is rain fed agriculture.
- Route passes close to Killiktepe Hill, ceramic shards from the Iron Age were found.
- The settlements in this area are large.
- The pipeline crosses the Sariz river and a national highway.

MAP 45: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** Seven settlements on this map will be directly impacted by the pipeline project (Yaylaci, Incedere, Corekdere, Kizilpinar, Sariz, Cavlak, Bahceli). Four have land intersected by the proposed pipeline (Yaylaci, Incedere, Corekdere, Kizilpinar) (L) and four are within 500m of the pipeline route (D). (Cavlak, Incedere, Sariz and Yaylaci). None are within 5km of a pump station, or a block valve station. Settlements impacted by traffic have not yet been identified. No settlements are 2km downstream of a river crossing.

- ***Surveyed:*** Four settlements were surveyed in the field (S) (Yaylaci, Sariz, Corekdere, Bahceli) and two settlements were surveyed by telephone (Kizilpinar, Incedere) (T).
- ***Not surveyed:*** Cavalak (300m from the pipeline), Killiktepe, Kuscu (1.5km from the pipeline), Kurdini (1.9km from the pipeline).

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Yaylaci (L) (D) (S)			
• ***Population:*** 800 inhabitants with 110 households, population has recently increased due to an increase in birth rate. • ***Safety:*** the pipeline is 600m from the centre of the settlement and 280m from the nearest residence. • ***Project attitude:*** generally positive. 46% of households expect to benefit from direct employment, 9% expect to benefit from land compensation. There were no major concerns. The majority of respondents would welcome a construction camp. • ***Land ownership & use*****:** local residents privately own 90 to 95% of land and 5% is communal. This is largely inherited land without title deeds. Seasonal grazing occurs during April, May and June and also	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 45 (Map 45C) (KPs 850.2 – 867.3): Teknell Settlement to Altinsogut Settlement, Kayseri Province

in September and October. Irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture (sugar beet, wheat, chick peas, beans, clover, apples, pears & walnuts), animal husbandry (1,000 sheep, 2,000 cattle), carpet weaving (silk carpets by younger and rugs by older local residents), bee keeping (minor), transportation, trade (small markets) and construction work are the main sources of livelihood. 40% of local residents are family labourers, only 1% have been unemployed for longer than a year, and 8% are seasonal labourers. • ***Availability & Skills:*** no previous pipeline experience. Local drivers, heavy machinery operators, repairs man, security personnel, food service, tree cutting, welders and construction workers are available. 73% of respondents would accept a temporary job. There are local sources of sand and stone that could be used in construction. • ***Accessibility:*** 5km to Sariz district centre. The settlement is accessible throughout the year except for January and February. Asphalt roads. • ***Information provision:*** 90% of the population is literate. The best information provision tools are TV, family, friends and via the Muhtar. • ***Environmental & cultural sites:*** spring/lake with thermal waters. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. • ***Services:*** electricity is available but there is no sewerage system or waste disposal system. Many services are provided by the nearest district centre (5km away). There is a primary school with 75-100 students. Although there is no health centre, there is a travelling health team. • ***Settlement problems:*** unemployment, poor waste disposal/ sewerage system and low incomes. It is, however, a relatively wealthy settlement. • ***Other:*** local residents are Avsar Turks.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Sensitive vegetation used by bees***	settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location. **Effectiveness of dust suppression** methods to be monitored daily and	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression and monitoring measures

Social Impact Table 45 (Map 45C) (KPs 850.2 – 867.3): Teknell Settlement to Altinsogut Settlement, Kayseri Province

	Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	are fully implemented.
	Land Potential complications in expropriation process.	**See Overview of the Land Acquisition Process in Appendix C9.**	**See Overview of the Land Acquisition Process in Appendix C9.**
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility of recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected.**
	Skills & resources Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials	**Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints.	**Potential positive benefits** to local settlements.

Social Impact Table 45 (Map 45C) (KPs 850.2 – 867.3): Teknell Settlement to Altinsogut Settlement, Kayseri Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Incedere (L) (D) (T)			
• ***Demographics:*** 680 inhabitants with 20% seasonal migration. • ***Safety:*** the pipeline is 600m from the centre of the settlement and 100m from the nearest residence. • ***Project attitude:*** generally positive with no major concerns. • ***Land ownership & use*****:** major land ownership is communal (60%). There is no seasonal grazing. Irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (three households produce honey as one of many income sources), hunting, fishing (five households fish as one of many income sources), forestry, mining, construction, transport, manufacturing, trade and education are the main sources of livelihood. 70% of respondents are family labourers. • ***Settlement accessibility:*** 3.5km to Sariz district centre. The settlement is accessible throughout the year except in December and January. • ***Information provision:*** 100% of the population is literate. The best information provision tool is the TV. • ***Environmental & cultural sites:*** historical remnant/statue. • ***Infrastructure:*** piped water is supplied to households however supply is irregular. The settlement is able to access water from a nearby neighbourhood as an alternative water source. • ***Settlement problems***: inadequate access to water and poor roads.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Bees*** Disturbance of any stationary hives located within 300m of the route.	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. Corekdere (L) **(S)**			
• ***Demographics:*** 900 inhabitants with 185 households. 30 households live abroad/ in the city and return to the settlement only in the summer. • ***Safety:*** the pipeline is 2.2km from the centre of the settlement and 2km from the nearest residence. • ***Disputes:*** there is an ongoing water dispute. There are two sources in the settlement, one of which is believed to cause cancer. This is the source most local residents use. A small number of families keep	***Construction hazards: animals*** Trench poses safety hazard for livestock	**Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 45 (Map 45C) (KPs 850.2 – 867.3): Teknell Settlement to Altinsogut Settlement, Kayseri Province

the source most local residents use. A small number of families keep the other source under their ownership. A lawsuit has been filed before the court on this matter. • ***Project attitude:*** generally positive. Specifically, 55% of households expect to benefit from direct employment, there were no major concerns. In addition, the majority of respondents would welcome a construction camp. However, there is a general feeling that *'they will forget us after they construct the pipeline'.* • ***Land ownership & use:*** 58% of land is privately owned by local residents, 40% is communal and 2% is state owned. Most local residents do not, however, have title deeds for their land. Instead the deeds are usually in the name of the deceased person. Seasonal grazing occurs during Spring, Summer and September and October. Irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture (wet and dry - sugar, beet, bean, potato, barley, wheat, rye, chickpea, clover); bee keeping (2-3 households), animal husbandry (cattle and sheep), construction, transport and trade are the mains sources of livelihood. Rug weaving occurs in almost all houses, 100 looms in summer and 200 in winter. 65% of respondents are family labourers. • ***Availability & Skills:*** no previous experience. Drivers, tree cutters and welders are available. 91% of respondents would accept a temporary job. There is also a local source of stone that could be used in construction. • ***Accessibility:*** 19km to Sariz district centre. The settlement has poor accessibility in January and February. • ***Information provision:*** 95% of the population are literate. The best local information provision tools are via the Muhtar and family members. • ***Infrastructure:*** there is piped water supply however supply is irregular. There is no alternative water source. There is electricity present but no sewerage or waste disposal systems. There is also telephone and mobile phone coverage • ***Services:*** there is a small market and a primary school that is	***Land*** Potential complications in expropriation process. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Accessibility to recruitment*** Decreased access to recruitment process.	**See Overview of the Land Acquisition Process in Appendix C9** Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. 	production.	**meetings:** issue to be discussed at meetings before and during construction.	
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Bahceli (L) **(T)**			
• ***Demographic:*** 3,760 inhabitants with 185 households. 10% seasonal migration. • ***Safety:*** 1.3km from the pipeline. • ***Project attitude:*** according to the Muhtar, inhabitants are generally positive with no major concerns. In addition, a construction camp would be welcome. • ***Land ownership & use:*** 80% of land is owned by local residents No seasonal grazing occurs. Irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (six households produce honey for their own consumption), hunting, fishing (two households fish, this forms one of many sources of income), manufacturing, trade & education are the main economic activities. 70% of the workforce are family labourers. • ***Accessibility:*** 0.5km to district centre. The settlement is accessible throughout the year. • ***Information provision:*** 85% of the population is literate. The best information provision tool is TV. • ***Infrastructure:*** piped, regular supply, no alternative water source • ***Settlement problems***: poor roads	***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing. ***Hunting*** Temporary reduction in game due to disturbance during construction.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisationfish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure. Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full. **Significance cannot be established at this time.**

Social Impact Table 45 (Map 45C) (KPs 850.2 – 867.3): Teknell Settlement to Altinsogut Settlement, Kayseri Province

		complaints procedure.	
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Access to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Environmental Impact Table 46 (Maps 46A and 46B) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils types from the previous section continue in this section of the route: • Mesic Coarse-loamy to Coarse-silty Xerorthents on alluvial plains. • Mesic Fine-loamy to Loamy-skeletal Xerochrepts on sloping lands, these are probably skeletal on moderately steep and steeper lands.	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity. Other potential impacts include: • channel alteration; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Reforestation.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
The route continues along rolling terrain on the western side of the Sariz River valley. Stream crossings increase in frequency as the valley widens, and the river meanders broaden. The valley is characterised by richer agricultural lands around Sariz, and farmland with scattered trees and bushes along the small creeks flowing down to the main river. Patches of irrigated arable land also occur here. The route crosses the Sariz River just east of the settlement of Kurudere, in a beautiful valley of emerald green water-meadows, washed yellow with buttercups in spring, and with many trees lining the meandering river, all lying between steep rocky slopes. Landscape sensitivities here are high. BVS-045 will be located at KP 880.5 within cultivated land. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 40m in length. Kurudere settlement lies c. 310m from the site.	Wet meadows along the Sariz River valley particularly susceptible to damage. Short-term construction modifications of landscape, highly visible during construction. Potential for short-term visual impact during construction for villagers in Kurudere settlement during construction at BVS-045.	Measures to reduce the impact of heavy machinery will be taken when crossing the Sariz River valley. These will include route narrowing, and use of moveable equipment mats to spread vehicle weight and avoid deep rutting. Construction will be undertaken at the driest time of the year (July to September) or removal / replacement of turfs may be necessary if schedules dictate work during wetter periods (March to June). Particular attention will be paid to the control of dust, noise and	**MODERATE IMPACT** The wet meadows / marshland in the Sariz River Valley will be impacted by the pipeline crossing, but if undertaken with care and sensitivity, this will last no more than a year or two. Minor impacts elsewhere. **MINOR IMPACTS** Given the relatively small size of the block valve station and the temporary nature of construction activities, visual impacts are anticipated to be

Environmental Impact Table 46 (Maps 46A and 46B) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		traffic during construction at BVS-045.	minor, subject to implementation of the specified mitigation measures.
Surface Waters			
The pipeline route crosses Sariz River near KP 880. River channel is irregular and meandering with a rectangular cross-section and central channel bars. Width of crossing is 25m and the bank-full width is c. 1.5m, although the floodplain is between 25 and 125m wide. Bed consists of silt and sand and the flow is perennial and of a uniform and tranquil type. Bank-side vegetation comprises shrubs, reeds and trees and riparian vegetation is fragmentary. Natural width controls exist at bluffs either side of the overflow channel and two bridges lie 1.3km upstream at Kemer and 350m downstream at Kurudere. Water samples taken 450m upstream of the crossing point indicate that this is a Class IV river. Kurudere settlement is c. 0.5km downstream of the crossing point.	Direct disturbance to bank and bed morphology through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in already poor water quality. Potential for short -term sedimentation and turbidity.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, Including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench.	**MINOR IMPACT** Disturbance will be short-term and limited to the immediate working area. Sedimentation of Sariz River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Archaeology and Cultural Heritage			
Three archaeological sites may be potentially affected by pipeline construction in this section and lie within the 100m Corridor: • Karayurt Mound (1st Degree Site*) – this site, which is now covered by a modern settlement, is a 'Classical Site' consisting of traces of Roman and Byzantine structures. • Cukurpinar Area (3rd Degree Site*) – a flat settlement located to the west of the Pipeline. Architectural remains are visible on the surface. • Golbasi Rock (1st Degree Site*) – flat settlement located to the east of Kurudere Settlement. No architectural remains are visible on the surface. The artefacts found can be traced down from Late Calcolithic to Roman periods. • Yayagecidi - 1st Degree • Kemer Mound - 1st Degree; * These sites have not yet been registered by the MoC and are provisionally assigned these classifications.	Potential for direct impacts, such as ground disturbance, at all these archaeological sites during pipeline and block valve station construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of these sites.	Cukurpinar Area is avoided through re-routing of the Pipeline. However, the site will also be fenced throughout the construction period, as the route will still pass close to it. The pipeline has been re-routed to avoid Golbasi Rock and Karayurt Mound. Potential impacts will therefore be avoided. All block valve stations and their access roads have been located to avoid known archaeological sites. However, particular care will be taken during construction of	**MINOR IMPACT** Impacts will be limited to the temporary disturbance of the setting of these archaeological sites and their peripheral features. **MINOR to MODERATE IMPACTS** During field confirmation of the BVS-045 site, the exact location will be chosen taking into consideration proximity to Kurudere Mound and Golbasi Rock. However, given the relatively small size of the block valve station and the

Environmental Impact Table 46 (Maps 46A and 46B) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Karayurt Mound and Cukurpinar area have been proposed for Registration by the regional preservation council BVS-045 will be located within 50m of Kurudere Mound (which is outside the 100m Corridor and is proposed for registration) and 100m of Golbasi Rock. The new access road to this site, c. 40m in length, will be within 30m of Golbasi Rock.		BVS-045. Further on-site assessment of the site will be undertaken prior to construction to confirm suitability of location. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	distance away from the archaeological sites, any impacts will be minor and limited to the temporary disturbance of the sites' setting peripheral features.

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

MAP 46: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There is one block valve station.

MAP 46: MAP HIGHLIGHTS

- Main land uses are rain fed agriculture, irrigated agriculture and pasture.
- Route passes close to Kurudere mound.

MAP 46: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** 10 settlements on this map will be directly impacted by the pipeline project (Altinsogut, Daridere, Gumussail, Fettahdere, Ayranlik, Karayurt, Incemagara, Kemer, Kurudere, Yeni). All of these settlements have land intersected by the proposed pipeline (L) and four (Karayurt, Kuderere, Altinsogut, Kemer) have houses within 500m of the pipeline route (or the settlement centre within 1km of the pipeline)(D). None are within 5km of a pump station. Two (Kurudere and Kemer) are within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. Two settlements are downstream of a river/creek; Kurudere is downstream of the pipeline on the Sariz river and Karayurt is on Tepe creek (R).

- ***Surveyed:*** two settlements (Ayranlit, Fettahdere) were surveyed in the field (S) and 14 settlements were surveyed by telephone (T).
- ***Not surveyed:*** Daridere (1.7km from pipeline), Mollahuseyin (1.9km from pipeline).
- ***Not on map:*** Yeni.
- ***Disclosure Meeting Location:*** Karayurt

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Altinsogut (L) (D) (T)			
• ***Demographics:*** 194 inhabitants. No seasonal migration. • Safety: the pipeline is 650m from the centre of the settlement and 600m from the nearest residence. • ***Project attitude:*** generally positive with no major concerns. A construction camp in the area would also be welcomed. • ***Land ownership & use:*** 50% of land is privately owned by local residents and 50% is communal. No seasonal grazing occurs. Irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (three households for own consumption), hunting, manufacturing, construction are the main sources of livelihood. 96% of workforce are family labourers.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

• ***Distance from settlement to district centre:*** the pipeline is 8km from the district centre (Sariz). • ***Settlement accessibility:*** 8km to Sariz district centre. The settlement has poor accessibility in December and January. • ***Information provision:*** Turkish is spoken. 95% of the population is literate. The best information provision tools include TV, radio and the telephone. • ***Environmental & cultural sites:*** a mausoleum • ***Infrastructure:*** piped water is supplied to households, however supply is irregular. A settlement fountain provides an alternative water source • ***Settlement problems:*** poor roads and infrastructure problem		settlement is within 500 m of construction work.	
	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage to be compensated for.**
	Land Potential complications in expropriation process.	**See Overview of the Land Acquisition Process in Appendix C9**	**See Overview of the Land Acquisition Process in Appendix C9**
		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In the event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

	Hunting Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	**Significance cannot be established at this time.**
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Accessibility to recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport need to be **taken into account** in the recruitment strategy.	**No residual impact expected.**
	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

		season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Gumussail (L) (T)			
• ***Demographics:*** 116 inhabitants with 60% seasonal migration. • ***Safety:*** the pipeline is 1.7km from the centre of the settlement and 1.6km from the nearest residence. • ***Project attitude:*** generally positive with no major concerns. • ***Land ownership & use:*** 95% of land is owned by local residents. No seasonal grazing occurs. Irrigation activities are undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (10 households as their main source of income) and transport. 80% of local residents are family labourers. • ***Accessibility:*** 10km to Sariz district centre. The settlement has poor accessibility during December and January.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Sensitive vegetation used by bees*** Dust may affect yields of	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Effectiveness of dust suppression** methods to be monitored daily and	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No significant impacts** predicted if dust suppression and monitoring measures

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

• ***Information provision:*** 100% of the population is literate. The best information provision tool is TV and the newspaper. • ***Infrastructure:*** piped, regular supply, there is no alternative water source. • ***Settlement problems:*** poor roads and inadequate access to water.	vegetation (eg grey clover) essential for nectar production. ***Accessibility to recruitment*** Decreased access to recruitment process	increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	are fully implemented. **No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Fettahdere (L) (S)			
• ***Demographics:*** 330 inhabitants with 81 households. The population is decreasing. This is due to migration of young population, and some residents only live in the settlement during summer. • ***Safety:*** the pipeline is 1.25km from the centre of the settlement and 650m from the nearest residence. • ***Disputes:*** uneasy relationship between the Muhtar and the imam. • ***Project attitude:*** mixed. The men positive about the project, but the women are concerned about the safety of children and animals. Specifically, 42% of households expect to benefit from direct employment, 15% expect to benefit from land compensation. There were no major concerns. In addition, the majority of respondents would welcome a construction camp. • ***Land ownership & use:*** 70% of land is owned by the local residents, 20% is communal, and 10% is leased. Local residents do not have title deeds. Seasonal grazing occurs during the spring and summer and in September & October. There is no irrigation. • ***Settlement livelihood:*** agriculture (wet and dry - wheat, barley, chickpea, bean, potato, famous for walnuts); animal husbandry	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in expropriation process. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **See Overview of the Land Acquisition Process in Appendix C9** **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison**	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of the Land Acquisition Process in Appendix C9** **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

chickpea, bean, potato, famous for walnuts); animal husbandry (cattle); and bee keeping are the main activities in the settlement (six households) The region is famous for its diverse flora and honey produced is regarded as very valuable. According to inhabitants bees fly over a distance of 4km and would be impacted by the construction of the pipeline, which is 1km from the settlement. Weaving (20 looms approx.) construction, transportation and manufacturing also carried out. 80% of adults of working age are family labourers and 10% have regular paid work. • ***Availability & skills:*** vehicle drivers are available. 58% of respondents would accept a temporary job. Stone and soil suitable for construction is available in the vicinity of the settlement. • ***Accessibility:*** 11km to Sariz district centre. The settlement has poor accessibility in February. • ***Information provision:*** 85% of the population is literate. The best information provision tools include TV, the Muhtar and via family members. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. There is electricity supply but no sewerage or waste disposal system. • ***Services:*** there is a school with 25 students, a market, and a travelling health team. • ***Settlement problems:*** unemployment, income, immigration. Poor settlement. No drinking water, because the piped water is not drinkable. There is no sewer system. Bee keepers from other provinces.	production. ***Accessibility to recruitment*** Decreased access to recruitment process	**meetings:** issue to be discussed at meetings before and during construction. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Ayranlik (L) (S)			
• ***Demographics:*** 600 inhabitants with 75 households, increasing in population due to high birth rates. • ***Safety:*** the pipeline is 1.1km from the centre of the settlement and	***Construction hazards: animals*** Trench poses safety hazard	**Livestock crossings** will be established at locations as	**Potential for accidents involving livestock.**

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

900m from the nearest residence. • ***Project attitude:*** the response to the project is mixed, 46% of inhabitants expect to benefit from direct employment, there were no major concerns. In addition, the majority of respondents would welcome a construction camp. • ***Land ownership & use:*** 40% of land is owned by local residents and 60% is communal. Most land owners do not have title deeds. Grazing occurs during all seasons of the year. Dry agricultural activities are carried out in the area covered by the pipeline. Irrigation occurs. • ***Settlement livelihood:*** agriculture (grain, herbs, potatoes, clover); animal husbandry (cattle & sheep); bee keeping; construction and rug weaving are all economic activities. 86% of the workforce are seasonal labourers. • ***Availability & Skills:*** there are four workers who worked in the construction of the Sivas natural gas pipeline. Other available skills are; driver, operator of heavy working machinery, security personnel, tree cutting, welder. 73% of respondents would accept a temporary job. Locally sourced sand and stone could be used in construction. • ***Accessibility:*** 9km to Sariz district centre. The settlement is accessible all year. There is a 14km asphalt road but 2km is constructed from loose binder dust. • ***Information provision:*** 90% of the population is literate. The best information provision tools are TV, family and via the Muhtar. • ***Infrastructure:*** piped water is supplied to households however the supply is irregular. There is no alternative water source. There is electricity supply but no sewerage or waste disposal system. There is telephone network and mobile phone coverage. • ***Services:*** there is a primary school, a health centre with a doctor, and a small market. • ***Settlement problems:*** lack of water, unemployment, waste disposal, dirty drinking water and garbage disposal.	for livestock ***Land*** Potential complications in expropriation process. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Skills & resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials	agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. **See Overview of the Land Acquisition Process in Appendix C9.** Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in	Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of the Land Acquisition Process in Appendix C9.** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **Potential positive benefits** to local settlements.

Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Methiye (L) (T)			
• ***Demographics:*** 170 inhabitants with 25% seasonal migration. • ***Safety:*** the pipeline is 2.2km from the centre of the settlement. • ***Project attitude:*** generally positive with no major concerns. In addition the majority of respondents would welcome a construction camp. • ***Land ownership & use:*** 50% settlement owned & 50% communal. Seasonal grazing and irrigation occurs.		***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

• ***Settlement livelihood:*** agriculture, transport, tourism, education and construction are the main economic activities. 90% of the workforce are family labourers. • ***Availability & Skills:*** previous experience of mining projects. • ***Accessibility:*** 57km to district centre. The settlement is accessible throughout the year. • ***Information provision:*** Turkish and Cerkezish are spoken. 100% of the population is literate. The best information provision tool is TV. • ***Infrastructure:*** piped, but the supply is not regular, the local spring is an alternative water source. • ***Settlement problems:*** poor roads, inadequate health care, inadequate child care.		warned and alternative sources of water to be provided.	
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Access to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Land Potential complications in expropriation process.	**See Overview of the Land Acquisition Process in Appendix C9.**	**See Overview of the Land Acquisition Process in Appendix C9.**
	Construction hazards: animals Trench poses safety hazard for livestock.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.
	Accessibility to recruitment	Winter road closures, seasonal migration and poor	**No residual impact expected**

Social Impact Table 46 (Map 46C) (KPs 867.3 – 882.1): Altinsogut Settlement to South of Kurudere Settlement, Kayseri Province

	Decreased access to recruitment process	transport will be **taken into account** in the recruitment strategy.

	Drinking water Potential for disruption or contamination of drinking water during construction.	The need for an **alternative source of water** will be evaluated prior to construction, and if necessary will be provided by the Project.	**No residual impact.**

Environmental Impact Table 47 (Maps 47A and 47B) (KPs 882.1 – 896.8): Karakoyun Mountain and Binboga Mountains Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils types from the previous section continue in this section of the route: • Mesic Coarse-loamy to Coarse-silty Xerorthents on alluvial plains. • Mesic Fine-loamy to Loamy-skeletal Xerochrepts on sloping lands, these are probably skeletal on moderately steep and steeper lands.	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity. Other potential impacts include: • channel alteration; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Reforestation.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
Relief increases south of Sariz River as the rolling terrain gradually gives way to rocky hills and stony uncultivated soils with juniper scrub and a wealth of wildflowers. The route emerges across a wide, rolling agricultural plain with scattered trees near Yesilkent, framed by steep mountains with conspicuous, exposed, longitudinal, folded strata. Rain-fed cereals occupy these lands, giving way to grazing on the hilly slopes. Forests occupy upland areas east and west of the RoW. Landscape sensitivity is moderate. The RoW crosses riparian forest near KP 877. Elsewhere, a dense network of small streams drains uplands across the pipeline route. Highway crossings between KPs 875 and 880 receive clear views of the route.	Short-term construction modifications of landscape, highly visible during construction.	• Reinstatement of the BTC Pipeline. • Replant disturbed woodlots and riparian forests.	**MINOR IMPACT** If re-instatement successful, impacts will be restricted to short-term.
Ecology			
Important Ecological Factors ESA 39 is identified between KP 886.8 and KP 887.3 for the globally-threatened plant species *(Verbascum meliltenense*). The IUCN status for this species is given in Table 5.20, Section 5.	Habitat destruction of montane steppe and habitats peripheral to cultivated land may result in the loss of	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 39 - 40. Diligence will	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction

Environmental Impact Table 47 (Maps 47A and 47B) (KPs 882.1 – 896.8): Karakoyun Mountain and Binboga Mountains Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
ESA 40 is identified between KP 894.9 and KP 896.8 for four globally-threatened plant species (*Thlaspi densiflorum, Allium glumaceum, Arabis aubrietioides* and *Paracaryum reuteri*) that occur along the pipeline route. In addition, one globally-threatened species (*Galium cornigerum*) occurs just east of the corridor parallel to ESA 40. The IUCN status for these species within ESAs 39 and 40 are given in Table 5.20, Section 5. Lesser Kestrel (globally-threatened) was recorded breeding, (between April and July inclusive), in Yesilkent Settlement. The protection status for this species is given in Table 5.21, Section 5.	individuals from populations of globally-threatened plants. Regular movement of heavy machinery or location of pipe dumps, construction yards or camps in the vicinity of Yesilkent settlement may disturb a globally-threatened breeding bird during nesting, feeding or indirectly, through habitat loss if temporary facilities are located near the settlement during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Preconstruction survey will establish the presence of possible nesting sites of the Lesser Kestrel within 500m of the pipeline route. If nesting sites are identified, avoidance of construction activity from April to July. Construction camps, pipe dumps/yards, borrow pits and fuel stores etc will not be	planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Impacts will be **MODERATE** if temporary construction facilities are located in the area during the breeding season.

Environmental Impact Table 47 (Maps 47A and 47B) (KPs 882.1 – 896.8): Karakoyun Mountain and Binboga Mountains Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		located within the vicinity of Yesilkent Settlement.	

Kahramanmaras Socio-Economic Overview

Demographics:
Kahramanmaras is the second largest of the pipeline provinces in terms of population with just over one million inhabitants, 20% of which (the highest of all surveyed provinces) live within a 4km corridor of the pipeline. Just under half of the province population live in urban areas and the province experiences the second highest survey density with 62 inhabitants per km^2. The average household size is six, mirroring the survey average. Rural areas are experiencing out-migration, whereas urban areas are experiencing in-migration. Population levels double during the summer months due to the in-migration of holidaymakers from Kadirli, Osmaniye and Adana. All individuals surveyed speak Turkish (the overwhelming majority being Sunni Muslims) and a very small percentage also speak Kurdish (0.35% of respondents). Settlements are more mixed in the northern area of the province, resulting in discernible tensions between groups of different origins. The area is characterized by religious conservatism.

Land:
The province is located in the transition zone between Central Anatolia in the north (relatively dry and mountainous) and the Cukurova region (the most fertile part of Turkey, with irrigation generally allowing two harvests per year). The northern portion of the province comprises Goksun district centre and surrounding settlements in a high altitude valley, all in close contact with each other. The southern portion, located on the lower slopes of the Taurus Mountains, has strong economic and cultural links with Adana province and Kadirli district centre, and benefits from more advanced living conditions and higher income levels. Private ownership, followed by communal ownership, is the main landownership form although there is high inequality and land polarisation. In the north, production of wheat and barley dominates due to the limited availability of irrigation (which, where present, allows for the production of sugar beet, beans, potato, maize and sunflowers). There is a preponderance of 'petty' landownership with subsistence agriculture dominating. In southern portions, the more widespread use of irrigation allows for greater product diversification. There is high use of fertilisers and agricultural machinery, and agricultural production is for national and international markets. The presence of irrigated cotton production and cheap labour has culminated in the area becoming a hub for textile factories.

Livelihoods:
Industrial activity is almost non-existent in the surveyed settlements, with the exception of Goksun (one of the two district centres surveyed). Overall, the province is ranked fifth of the pipeline provinces in terms of a combination of income and wealth assets of the surveyed settlements, and sixth in terms of average household income. Living conditions were thought to have deteriorated, particularly due to an increase in the cost of agricultural inputs, alongside only a small increase in product prices. Agriculture and livestock breeding are the main forms of livelihood. A significant number of people owe money to agricultural loan co-operations and few own land titles.

Infrastructure & Services:
Electricity, water and telephone networks are available (although regularity of electricity supply is a problem). Sewerage systems are present only in the municipality and district centres. Televisions, the basic source of obtaining national news, are present even in the poorest settlements. Average literacy rates are high (87% in surveyed settlements) despite the lack of schools in some settlements, although education levels are lower in the northern area of the province. Almost 40% of respondents have attained a primary school education, 31% a secondary education and 3% a university education.

Key Problems:
Inadequate 'livelihood possibilities' and the collapse of agriculture production were raised as the main problems. Health services are inadequate in all surveyed settlements with the exception of municipal and district centres, although at the provincial level Kahramanmaras has the second highest number (after Adana) of active settlement clinics of all the pipeline provinces (Ministry of Health). The lack of nurses and health centres in the surveyed settlements causes particular problems during emergencies.

Project Attitude:
Generally, surveyed settlements are positive about the pipeline project. However, in light of recent declines in agriculture profitability, relatively infertile lands and limited potential for irrigation, surveyed settlements have high employment expectations associated with the pipeline construction. A small proportion are concerned about damage to agricultural production, crops and land.

Social Impact Table 47 (Map 47C) (KPs 882.1 – 896.8): Karakoyun Mountain and Binboga Mountains Area, Kahramanmaras Province

MAP 47: PROJECT INFORMATION

There is no pump station, construction camp or block valve station in the area.

MAP 47: MAP HIGHLIGHTS

- Rain fed agriculture and pasture are the major land use types.
- Areas of riparian forest.
- Network of streams drain uplands across the pipeline route.
- Pipeline crosses two National highways.

MAP 47: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** four settlements will be directly impacted by the pipeline, three settlements (Dogankonak, Yesilkent, Yesilkent Koyu) have land intersected by the proposed pipeline (L); and one settlement (Yalak) is within 500m of the pipeline route (D). No settlements are within 5km of a pump station or construction camp (P/C), or within 2km of a block valve station (B). Settlements impacted by traffic have not yet been identified. No settlements are downstream of a river/creek pipeline crossing (R).

- ***Surveyed:*** Dogankonak, Yesilkent and Yesilkent Koyu were surveyed by telephone (T).
- ***Not surveyed:*** two settlements have not been surveyed, Yalak (800m from the pipeline, nearest house from the pipeline is 175m), Haydan (1.2km from the pipeline).
- ***Not on the map:*** Yalak.

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Dogankonak (L) (T)			
• ***Demographics:*** 199 with 100% seasonal migration. • ***Safety:*** nearest house 1km from pipeline, centre of settlement is 1.1km from the pipeline. • ***Project attitude:*** there are no major concerns, and according to the Muhtar a construction camp would be welcome. • ***Land ownership & uses:*** 80% of land is communal, there is seasonal grazing. There is no of seasonal irrigation. • ***Settlement livelihood:*** agriculture, construction, education and local government are the main sources of livelihood. • ***Accessibility:*** the settlement is accessible in winter and 26km to the district centre.	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land***	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **See Overview of Land**	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of Land Acquisition Process in**

Social Impact Table 47 (Map 47C) (KPs 882.1 – 896.8): Karakoyun Mountain and Binboga Mountains Area, Kahramanmaras Province

district centre. • ***Information provision:*** 90% of the population is literate. Local sources of information are phone and television. • ***Infrastructure:*** piped water is available. There is regularity of water supply. There is no alternative water source. • ***Settlement problems:*** inadequate access to water, and the need for forest fields.	Potential complications in expropriation process. ***Access to recruitment*** Decreased access to recruitment process	**Acquisition Process in Appendix C9.** Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**Appendix C9.** **No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Yesilkent 1 (L) (T)			
• ***Demographics:*** 83 inhabitants with 5% seasonal migration. • Safety: 850m from the pipeline. • ***Project attitude:*** generally positive with no major concerns. In addition the majority of respondents would welcome a construction camp. • ***Land ownership & use:*** 90% of land is owned by local residents. No seasonal grazing or irrigation occurs. • ***Settlement livelihood:*** agriculture and construction are the main economic activities. 60% of the workforce are family labourers. • ***Accessibility:*** 21km to district centre. The settlement is accessible throughout the year. • ***Information provision:*** 100% of the population is literate. The best information provision tool is TV. • ***Infrastructure:*** piped, regular supply, no alternative water source • ***Settlement problems:*** low income.	***Access to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. **Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.**

Social Impact Table 47 (Map 47C) (KPs 882.1 – 896.8): Karakoyun Mountain and Binboga Mountains Area, Kahramanmaras Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Yesilkent 2 (L) (T)			
• ***Demographics:*** 83 inhabitants. No seasonal migration. • ***Safety:*** 840m from the pipeline. • ***Project attitude:*** generally positive with no major concerns. In addition, the majority of respondents would welcome a construction camp. • ***Land ownership & use:*** 92% of land is subject to share-cropping. No seasonal grazing or irrigation occurs. • ***Settlement livelihood:*** agriculture, bee keeping (two households produce honey for own consumption), manufacturing, transport, trade, education and construction are the main economic activities. 75% of the workforce are farmers. • ***Accessibility:*** 21km to district centre. The settlement is accessible throughout the year. • ***Information provision:*** Turkish & Cerkezish is spoken. 99% of the population is literate. The best information provision tool is TV. • ***Environmental & cultural sites:*** churches. • ***Infrastructure:*** piped water is supplied to households. There is no alternative water source. • ***Settlement problems:*** watering canals must be rearranged, inadequate access to water, and animal farming should be supported by state.	***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Land*** Potential complications in expropriation process. ***Construction hazards: humans*** Working areas pose safety hazard to residents,	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **See Overview of Land Acquisition Process in Appendix C9.** **Road safety training** will be held in schools prior to construction commencing. **Community liaison**	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **See Overview of Land Acquisition Process in Appendix C9.** **Continued attention** to mitigation measures will be critical to prevent injury.

	particularly small children. Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**meetings** held prior to and during construction will include safety briefings. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Benefits** from health and safety awareness raising. **Any additional damage to be compensated for.**

Environmental Impact Table 48 (Maps 48A and 48B) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Coarse-loamy to Coarse-silty Xerorthents on alluvial plains. • Rocky land (KP 887 – 890). • Mesic Loamy-skeletal Xerochrepts on hills.	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity; • channel alteration; • soil contamination; • waterlogging.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Reforestation. • Time construction to avoid irrigation periods. • Allow soils time to drain. Use equipment mats as required.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.
Landscape and Visual			
The route crosses non-intensive cereal fields on undulating ground and steppe used for grazing animals on hillier terrain. Forests occupy upland areas east and west of the RoW. The route runs parallel and close to a main highway throughout this section. In addition, several settlements are in close proximity to the route, and other significant man-made elements in the landscape include electricity cables and an ancient tumulus at KP 895. Irrigated crops occur in the Goksun valley in the southern part of the section. Landscape sensitivities are low. Construction Camp C will be tentatively located at KP 908.5, although the precise location for this camp is still being finalised. The camp will occupy an area of c. 16.7ha.	Short-term construction modifications of landscape, highly visible during pipeline construction and through the presence of the temporary Construction Camp C during the construction period.	• Reinstatement of the BTC Pipeline. • Replant disturbed woodlots and riparian forests.	**MINOR IMPACT** If reinstatement is successful, impacts will be localised and restricted to short-term.

Environmental Impact Table 48 (Maps 48A and 48B) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Ecology			
Important Ecological Factors ESA 41 is identified between KP 902.9 and KP 909.7 for ten globally-threatened plant species (*Hedysarum candidissimum, Astragalus elbistanicus, Dactylorhiza osmanica var. anatolica, Arabis aubrietioides, Allium tauricola, Centaurea holtzii, Verbascum leianthoides, Paracaryum reuteri, Achillea magnifica* and *Phlomis brunneogaleata*) and one nationally-threatened plant (*Onobrychis sulphurea var. sulphurea*). In addition, one nationally-threatened plant (*Onobrychis sulphurea var. sulphurea*) occurs just west of the corridor parallel to ESA 41. The IUCN status for these species are given in Table 5.20, Section 5. Construction Camp C will be located within ESA 41. BVS-046 will be located at KP 905.0 on cultivated land and plain steppe also within ESA 41. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 30m in length. At KP 910.5 one Barred Warbler (nationally-threatened) was recorded. The protection status for this species is given in Table 5.21, Section 5.	Habitat destruction of plain steppe or areas peripheral to cultivated lands may result in the loss of individuals from populations of globally-threatened plants during pipeline and BVS construction and the location of the temporary construction camp within ESA 41. Potential for direct disturbance to a nationally-threatened bird during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 41. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. In addition, prior to construction of the Construction Camp C and BVS-046, a site specific survey	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACT** Based on the mitigation measures described, the small area of habitat affected and the temporary nature of construction activities, it is predicted that only minor impacts on the biological environment will occur as a result of construction activities at BVS-046. This assessment will be confirmed by the site-specific survey prior to construction. **MINOR IMPACTS** at most for the Barred Warbler, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding

Environmental Impact Table 48 (Maps 48A and 48B) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		will be undertaken by an ecological specialist to identify and locate threatened species at the site and at any surrounding areas potentially affected by construction activities. Based on the findings of this survey, appropriate mitigation will be determined. Shrubs, thickets and dense vegetation along the RoW will be cleared outside the breeding season for the Barred Warbler.	season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.
Noise			
Noise sensitive receptors are located at: • Keklikoluk settlement (Goksun District) including some outlying dwellings located directly adjacent to the pipeline route; and • Mehmetbey settlement (Goksun District) c. 80m from the centreline of the pipeline. Blasting works may also take place during pipeline construction within the vicinity of Keklikoluk settlement.	Noise impacts are expected to occur at: • Keklikoluk settlement during all phases of pipeline construction including soil stripping, trenching, pipe stringing, bending, welding/lowering and backfilling; • Mehmetbey settlement during soil stripping, welding/ lowering, backfilling, bending and trenching. Blasting works will also give rise to noise and vibration at Keklikoluk.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised.	**MAJOR IMPACT** Due to the proximity of the edge of Keklikoluk settlement to the Pipeline, noise impacts are expected to occur throughout the construction programme. Stockpiling of spoil, where possible, and mobile noise barriers, will be used to screen nearby dwellings from construction works to the maximum extent possible. However, those nearest may still be exposed to temporary construction noise levels that exceed 70dB(A). It is important to emphasise this is a cautious assessment. The construction programme will make

Environmental Impact Table 48 (Maps 48A and 48B) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers to screen dwellings from construction works, for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	provision for a further assessment based on the true numbers of receptors affected and separation distances of receptors from noise sources and take whatever actions are necessary to reduce impacts to an acceptable level. Blasting works will also give rise to noise and vibration at this settlement, which due to the proximity of the edge of the settlement to the Pipeline, could give rise to structural damage to outlying buildings, in addition to annoyance at residential properties. The Contractor will carry out detailed noise and vibration predictions once the specific blasting methods have been developed. The proposed method of working and mitigation measures will be agreed with the relevant authorities in advance of works taking place. Residents will also be notified in advance of works involving blasting. Noise impacts will also occur at Mehmetbey during soil

Environmental Impact Table 48 (Maps 48A and 48B) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
			stripping, welding/lowering and backfilling.

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

MAP 48: PROJECT INFORMATION

There is a primary construction camp (Lot C) in the area, located on unregistered pastureland. It will require 16.74ha. There is also a block valve station in the area.

MAP 48: MAP HIGHLIGHTS

- Rain fed agriculture and pasture are the major land use types.
- Forests occupy upland areas east and west of the RoW.
- Route passes close to Mezarlik Hill and tumulus.
- Pipeline corridor runs alongside a National highway.
- Pipeline crosses two energy transmission lines and the Huseyinli River.

MAP 48: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** six settlements will be directly impacted by the pipeline project (Bozhoyuk, Keklikoluk, Mahmutbey, Mehmetby, Mursei, Tahirbey) and will have land intersected by the proposed pipeline (L). Four of these settlements (Mehmetbey, Keklikoluk, Tahirbey, Mahmutbey) are within 500m of the pipeline (D). Two settlements (Mehmutbey, Mahmutbey) are within 5km of a construction camp, one (Tahirbey) is within 2km of the block valve station (B), and none are near a pump station (C/P). One settlement, Mehmetbey is at a river crossing (Huseyinli river).

- ***Surveyed:*** one settlement (Bozhoyuk) was surveyed in the field (S). Five settlements (Keklikoluk, Mursei, Tahirbey, Mahmutbey, Mehmetbey) were surveyed on the telephone (T).
- ***Disclosure Meeting Location***: Mehmetbey

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Keklikoluk (L) (D) (T)			
• ***Demographics:*** 187 inhabitants, 50% of the population migrates. • ***Safety:*** nearest house 40m from pipeline, centre of settlement is 350m	***Construction hazards: humans***	**Road safety training** will	**Continued attention** to

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

from pipeline. • ***Project attitude:*** a construction camp would be welcome, although the people are concerned that the pipeline might cause an explosion. • ***Land ownership & use:*** 50% of land is communally owned, There is seasonal grazing. Crops grown are wheat, sunflowers, sugar beet, bean and chickpea, the land is not very fertile. • ***Settlement livelihood:*** agriculture and animal breeding activities are the main sources of livelihood, although some local residents are working in Germany. • ***Availability & skills:*** two out of 24 construction skills present. • ***Accessibility:*** the settlement is accessible all year, and is 22km from the district centre. • ***Information provision:*** 100% of the population is literate. Main source of information is television. • ***Services:*** there is an elementary school. • ***Infrastructure:*** piped water is available and regular. • ***Settlement problems:*** inadequate access to water.	Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in expropriation process. ***Accessibility to information*** Sectors of the population	be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations as agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. **See Overview of Land Acquisition Process in Appendix C9.** **Communication with settlement** must take into account settlement	mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage to be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of Land Acquisition Process in Appendix C9.** **Any change can highlight and exacerbate existing divisions** in communities.

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6):
Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

	may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Accessibility to recruitment*** Decreased access to recruitment process	characteristics to ensure equal access to information for all residents. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	Mitigation measures will keep this to a minimum. **No residual impact expected**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Mursei (L) (T)			
• ***Demographics:*** 290 inhabitants with 10% of the population migrating. • ***Safety:*** nearest house 1.8km from pipeline, centre of settlement is 2km from pipeline. • ***Project attitude:*** according to the Muhtar local residents would welcome a construction camp. • ***Land ownership & use:*** 90% of land is communally owned, and 10% privately owned by local residents. Sugar beet is grown. No irrigation is used. • ***Settlement livelihood:*** agriculture, bee keeping (three households), construction and trade are the main sources of livelihoods. • ***Accessibility:*** the settlement is accessible between February and November. The settlement is 18km from the district centre. • ***Information provision:*** 80% of the population is literate. Best local information provision mechanisms are the telephone and television. • ***Environmental & cultural sites:*** a mausoleum • ***Infrastructure:*** piped water is available with regular supply. There is no alternative water source. • ***Settlement problems:*** inadequate access to water, low incomes and the land is poor.	***Land*** Potential complications in expropriation process. ***Accessibility to recruitment*** Decreased access to recruitment process ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	**See Overview of Land Acquisition Process in Appendix C9.** Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**See Overview of Land Acquisition Process in Appendix C9.** **No residual impact expected** **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6):
Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Bozhoyuk (L) (S)			
• ***Demographics:*** 2,500 inhabitants with 400 households. • ***Safety:*** centre of settlement is situated 2.8km from the pipeline. • ***Project attitude:*** community is not hostile to pipeline, their general attitude is positive and they hope that there will be temporary jobs in the construction phase. A construction camp would be welcome. • ***Land ownership & use:*** There is seasonal grazing all year. A diverse livestock. Seasonal irrigation undertaken. • ***Conflict over land rights & ownership:*** Occasional conflict between families/ tension between two different groups is observed. There are no ongoing unresolved disputes. A municipality with quite "nationalist" attitudes. The sub-settlement of Akboyum consists of citizens of Kurdish origin. • ***Settlement livelihood:*** the main economic activities are agriculture, forestry and animal husbandry. Trade and education are also important activities. Primarily wheat and some sugar beet are cultivated. • ***Availability and skills:*** 73% of respondents will accept a temporary job. • ***Accessibility:*** inaccessible in January and February. The settlement is 107km from the district centre.	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in expropriation process. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **See Overview of Land Acquisition Process in Appendix C9.** Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of Land Acquisition Process in Appendix C9.** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6):
Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

• ***Information provision:*** 99% of the population is literate. The best sources of national information are TV, local news via settlement policeman and Muhtar. The best local source of information is the Muhtar. • ***Environmental & cultural sites:*** historical remains especially in the form of treasury and monuments are likely to be encountered during the construction process of the pipeline. Civilian architecture. • ***Infrastructure:*** piped water is available. There is no regularity of water supply and usually there are cuts and interruptions in water flow for 2-3 hours per day. There is no alternative water source. There is no sewerage system and inhabitants rely on the Municipality of Goksun to empty the cesspits because the Municipality of Bozhuyuk does not have the means to do so. Consequently they are not always emptied. • ***Services:*** phone, mobile systems are available. The municipality owns a tractor, an ambulance, a service vehicle, an official vehicle and a bus. Coffee houses, shops, transport and sport facilities are also available. There is a primary school with one teacher in the settlement. The school serves the neighbouring settlements. There is a multi-programmed high school. Health facilities include a clinic, with a doctor and a midwife. • ***Settlement problems:*** water supply and poverty. Political unrest is apparent, ethnic tension between two groups, discrimination in provision of services.	***Accessibility to recruitment*** Decreased access to recruitment process ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Forestry*** Loss of a resource used by settlements. Increased expenditure on other fuel sources.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure.	**No residual impact expected** **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Tahirbey (L) (D) (B) (T)			
• ***Demographics:*** 83 inhabitants, no migration occurs. • ***Safety:*** centre of settlement is situated 650m from pipeline. Nearest household is 600m from the pipeline. • ***Project attitude:*** according to the Muhtar, local residents would welcome a construction camp. There are no major concerns.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison**	**Continued attention** to mitigation measures will be critical to prevent injury.

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

welcome a construction camp. There are no major concerns. • ***Land ownership & use:*** 70% of land is communally owned. No seasonal grazing takes place. No use of temporary irrigation. • ***Settlement livelihood:*** agriculture and bee keeping (by two families, for their own consumption) are the main sources of livelihood. • ***Accessibility:*** accessible between March and November. The settlement is 14km to the nearest district centre. • ***Information provision:*** Turkish and Cerkezish. Population is 90% literate. Best local information provision mechanisms are television and phone. • ***Environmental & cultural sites:*** none. • ***Infrastructure:*** no piped water. The settlement fountain is the only source. • ***Services:*** there is an elementary school. • ***Settlement problems:*** inadequate access to water, emigration particularly of younger generations leaving behind an ageing population.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**meetings** held prior to and during construction will include safety briefings. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

	Land Potential complications in expropriation process.	**See Overview of Land Acquisition Process in Appendix C9.**	**See Overview of Land Acquisition Process in Appendix C9.**
	Drinking Water Potential for contamination of drinking water by sediment or accidental spills	**Alternative sources of water** will be provided during construction to settlements that use water channels for drinking that are crossed by the construction activities.	**No residual impact**
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Accessibility to recruitment Decreased access to recruitment process ***Block Valve Station*** Refer to Environmental Impact Tables and the Resettlement Action Plan	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**

SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**MITIGATION**	**RESIDUAL IMPACTS**
Mehmetbey (L) (D) (C) (T)			
• ***Demographics:*** 200 inhabitants with no migration. • ***Safety:*** the settlement centre is 225m from the pipeline. The nearest house 50m from pipeline. • ***Project attitude:*** generally positive, providing construction workers do not visit the settlement. Also, it was suggested that the pipeline should use unproductive lands on the other side of the highway. Very conservative settlement with strict rules and traditions. A minority are concerned about the possible disruption of the social harmony. • ***Perceived benefits of construction camp:*** local residents hope to benefit from the opportunity to sell dairy and fish products to camp workers. During the second consultation meeting, inhabitants were more positive compared to the first meeting. As the camp has moved closer to the settlement they expect more benefits. • ***Land ownership & uses:*** 95% of land is communally owned. There is seasonal grazing and seasonal irrigation is undertaken. At the camp site, land is uncultivated and not used, it was previously rented out to local residents in Kayseri. • ***Settlement livelihood:*** agriculture, fishing (nine families), construction, trade, education and dairy production. There are two fishing farms, one owned by a local resident and the other by a cooperative established by 83 local residents. Connected to these farms there are two fish restaurants. • ***Availability & Skills:*** two out of 24 construction skills. 10 to 15 people have worked in infrastructure projects including dam & road construction and one person has been a heavy earth mover operator	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

construction and one person has been a heavy earth mover operator for 15 years. There are both skilled and unskilled workers. No previous pipeline experience. • ***Accessibility:*** the settlement is accessible throughout the year although the roads are of poor quality. • ***Information provision:*** 98% of the population is literate. Best local information provision mechanisms are television and telephone. • ***Infrastructure:*** piped water is available. There is regularity of water supply. There is no alternative water source. Adequate water for settlement only, however, there may be possibility of extracting underground water. • ***Services:*** good electricity system and telephone network. No sewerage system, and not in mobile or satellite coverage area. Two fish restaurants, one small grocery store, three trucks, one minibus and six or seven tractors. No coffee shop. • ***Other:*** the settlement has asked that there be strict discipline of the construction workers. There is fear of theft and drunkenness. There is a problem with the neighbouring settlement of Mahmutbey, as the camp site is within their borders yet closer to Mehmetbey.		erected in areas of danger for livestock.	compensation will be facilitated by the Projects complaints procedure.
	Land Potential complications in expropriation process.	**See Overview of Land Acquisition Process in Appendix C9.**	**See Overview of Land Acquisition Process in Appendix C9.**
	Fishing Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility of information Sectors of the population may not have access to project related information	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

	on employment opportunities, potential disruption to utilities, etc.	for all residents.	
	Skills Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials.	**Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints.	**Potential positive benefits** to local settlements.
		Groundwater During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
	Conservative settlement Construction workers are more likely to offend inhabitants	**Construction workers to be remind**ed of the importance of appropriate behaviour in daily **briefings. Any** interaction between construction workers and communities (eg use of local shop) to be carefully monitored.	**Low likelihood of significant impacts.** Impacts arising from breeches of rules and procedures. All incidents to be rapidly resolved and used as examples to reinforce procedures.

Social Impact Table 48 (Maps 48C) (KPs 896.8 – 910.6): Keklikoluk Settlement to Mehmetbey Settlement, Kahramanmaras Province

	Construction camps Primary receptors of impacts resulting from construction workers	**Monthly community liaison** meetings will be held. **Preferential employment** opportunities **Project to liase** with local health authorities BTC Company to look at opportunities to cooperate in providing **health awareness training.**	**Low likelihood of significant impacts.** Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures. **Low likelihood of significant health impacts**. **Benefits** from raising health awareness of workforce (many of whom are local). Further positive benefits dependent on scale of social investment activities.

Environmental Impact Table 49 (Maps 49A and 49B) (KPs 910.6 – 924.6): Goksun Plain, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Fine-silty Xerorthents in irrigated valley soils. • Mesic Coarse-silty Xerorthents where headlands begin to encroach on the valley. • Mesic Coarse-loamy Shallow Dystric Xerochrepts near southern headlands.	Main potential impacts include: • soil productivity; • sediment; • channel alteration; • soil contamination; • waterlogging.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Time construction to avoid irrigation periods. Allow soils time to drain. Use equipment mats as required.	**MINOR IMPACT** Soil productivity losses are predicted to last less than 3 months after construction is completed. In areas where waterlogging occurs, water is predicted to remain in surface depressions for less than 3 months after construction.
Landscape and Visual			
The route enters the Goksun valley, an area of irrigated agriculture bordered by lightly-forested hills. Numerous tributaries cross the Pipeline to be diverted into fields or flow directly into the Huseyinli River. Shortly after crossing the Huseyinli River around KP 902, the valley suddenly broadens out into a flat plain, largely designated to irrigated agriculture. Forests cover slopes east and west of the valley; riparian forests occupy stream banks, and linear plantations mark field boundaries. Landscape sensitivities are low. The highway diverges towards Goksun town, which lies about 2km to the east. A dense population and the motorway render the Pipeline highly visible.	Short-term construction modifications of landscape, highly visible during construction.	• Reinstatement of the BTC Pipeline. • Replant disturbed woodlots, field boundary forests, and riparian forests.	**MINOR IMPACT** If reinstatement is successful, impacts will be localised and restricted to short-term.
Surface Waters			
The pipeline route continues to parallel Huseyinli River before crossing it. River channel is irregular and meandering, with a trapezoidal cross-section and pool and riffle bars. Some riffles have been constructed to increase	Direct disturbance to bank and bed morphology through physical works, and indirectly,	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, for the	**MINOR IMPACT** Disturbance will be short-term and limited to the immediate

Environmental Impact Table 49 (Maps 49A and 49B) (KPs 910.6 – 924.6): Goksun Plain, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
backwater to irrigation offtakes. Width of crossing is 26m and the bank-full width is 13 – 14m, although the floodplain is between 26 – 130m wide. Bed consists of gravel and cobbles and the flow is perennial, of a pool and riffle type. Bank-side vegetation comprises grass, shrubs and deciduous trees and riparian vegetation is fragmented. Water samples taken 680m downstream of the crossing point indicate that this is a Class II river.	due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Therefore, potential for short-term sedimentation and turbidity. However, the water quality classification indicates that Huseyinli River is only slightly polluted and further degradation in quality will be avoided.	protection of surface waters, Including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities, such as Kurudere settlement, and provide where necessary if sedimentation and turbidity persist for more than 3 days at the community.	working area. Sedimentation of Huseyinli River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Groundwater			
The route passes over the Goksun Plain for the majority of this section, comprising areas of both unconfined and confined aquifer. Water samples were taken from the unconfined aquifer at four locations: • Well Site No. 10, (DSI 25297, Nebioglu Site), c. 2.3km east of the route (KP 914.6); • Well Site No. 11, (DSI 25294, Hacimirza Settlement), c. 3.8km east of the route (KP 914.6); • Well Site No. 12, (DSI 28483), c. 4.2km east of the route (KPs 916.4 – 917.7); • Well Site No. 13, (DSI 28486), c. 4km east of the route (KPs 917.7 – 919.4). Results indicate that groundwater quality is Class I, with the exception of groundwater taken from Well Site No. 10, which was Class II. BVS-047 will be located over the unconfined aquifer at KP 924.1 within cultivated land. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 30m in length.	Groundwater quality in much of this area is high and suitable for drinking water supply (post disinfection) and water supply for food industries. Potential for moderate and localised impacts to groundwater quality from construction of both the Pipeline and BVS-047.	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including: • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • Construction camps and other temporary facilities will not be located in areas of Class 1 unconfined aquifers or within 50m of springs or wells. Soakaways will not be used as a means for disposal of treated wastes in such locations.	**MODERATE IMPACT** The presence of a Class I unconfined aquifer means that there is the potential for moderate impacts during pipeline and BVS construction. Strict adherence to the mitigation measures contained in the EMMP (see Appendix C1) and PPP (see Appendix C4) will be required.

Environmental Impact Table 49 (Maps 49A and 49B) (KPs 910.6 – 924.6): Goksun Plain, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• Fuels and other oils will not be stored in areas of Class 1 unconfined aquifers. If it is necessary to store fuels etc in such locations they will be stored in bunded areas on impermeable bases and the inventories will be kept to a practical minimum.	
Noise			
Caglayan settlement is located c. 217m from the centreline of the pipeline.	Short-term noise impacts are expected to occur at Caglayan settlement during soil stripping.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings and where possible, utilising existing screening, including that arising from the stockpiling of materials. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers to screen dwellings from construction	**MINOR IMPACT** Short-term noise impacts are expected to occur during soil stripping. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.

Environmental Impact Table 49 (Maps 49A and 49B) (KPs 910.6 – 924.6): Goksun Plain, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		works for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	
Archaeology and Cultural Heritage			
There are two archaeological sites in this section within the 100m Corridor: • Gumgum Hill (3rd Degree Site - registered by the MoC). The site comprises five sites, of which the second largest crossed by the route at KP 912.6. Pottery pieces dating from the Late Roman and Byzantine periods were observed in the area during route narrowing investigations. However, it was noted that archaeological finds have been illegally removed from the site; • Tasoluk Settlement (Igdelik Mound) (3rd Degree Site - registered by the MOC*) – Classical monumental site. It consists of traces of Roman and Byzantine structures, mosaics, peribolos wall, towers, a large church and necropolis. Due to the thick alluvial deposit accumulated over the settlement, it is impossible to define its boundaries.	Gumgum Hill will potentially experience ground disturbance during pipeline construction. Tasoluk Settlement will experience structural damage as a result of construction activities.	The pipeline has been re-routed to avoid Gumgum Hill. Tasoluk Settlement will be further investigated prior to construction to establish the boundaries of the site and a safe route through. The classification of this site will also be confirmed during pre-construction archaeological surveys. If a safe route is not possible, salvage excavations will be carried out at this site prior to the commencement of construction activities. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ and a member of the Ministry of Culture. If blasting is required, then it will be conducted in such a way that it does not pose a threat to the integrity of buildings still standing	**MINOR IMPACT** Residual impacts cannot be determined precisely for Tasoluk Settlement at this stage and will be subject to further investigation prior to construction. Archaeological investigations prior to construction will establish the full extent of the site. However as investigations are expected to find a safe route through these sites, the ultimate scale of impact is likely to be minor and short-term in duration. Assuming Gumgum Hill is fenced, impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Environmental Impact Table 49 (Maps 49A and 49B) (KPs 910.6 – 924.6): Goksun Plain, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		on the site. To avoid vibration impacts, percussive piling will be not allowed within 100m of Tasoluk Settlement.	

Social Impact Table 49 (Map 49C) (KPs 910.63 – 924.6): Goksun Plain, Kahramanmaras Province

MAP 49: PROJECT INFORMATION

A primary Construction Camp (Lot C) is located in the area (refer also to map 53). It is 16.74ha in size and located on unregistered pastureland. Two options were originally considered. This is the preferred site as the other option was located on cultivated land with trees. There is no pump station or block valve station in the area.

MAP 49: MAP HIGHLIGHTS

- Predominant land use is irrigated agriculture, there are also small areas of pasture.
- The Huseyinli River crosses the pipeline.
- Forests cover the slopes east and west of the valley.
- Pipeline crosses a National highway.
- There are two archaeological sites: Gumgum Hill; Igdelik Mound and an ancient settlement including ruins of a church and other buildings.

MAP 49: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** four settlements will be directly impacted by the pipeline project. They will each (Caglayan, Yenimhalle, Yiricek, Tasoluk) have land intersected by the proposed pipeline (L). Two of these (Tasoluk, Caglayan) are also situated within 500m of the pipeline (D). No settlements are within 500m of a pump station (P). Camkopru and Gumgum are near a construction camp (C). Tasoluk is within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. One settlement is downstream of a river/creek crossing (Goksin is downstream of the Huseyinli river).The campsite location has been changed. As such there are no longer any settlements on this map near a construction camp.

- ***Surveyed:*** three settlements (Goksun, Yiricek, Tasoluk) were surveyed in the field (S). Two settlements (Caglayan, Yenimhalle) were surveyed via telephone (T).
- ***Disclosure Meeting Location:*** Tasoluk

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	*RESIDUAL IMPACTS*
Camkopru & Gumgum (C) (S)			
• ***Demographics:*** there are six households in Camkopru and five households in Gumgum. • ***Safety:*** Camkopry is 750m from the pipeline and Gumgum is 250m from the pipeline. Both are also near a primary construction camp. • ***Land ownership at construction campsite:*** the campsite is 16.74ha in size and is unregistered pasture land, used by the Mahmutbey settlement. • ***Project attitude:*** generally positive, although local residents are concerned about the security of the pipeline	**Construction camps** Primary receptors of impacts resulting from construction workers	**Monthly community liaison** meetings will be held. **Preferential employment** opportunities **Project to liase** with local health authorities.	**Low likelihood of significant impacts.** Possibility of Impacts arising from breaches of rules and procedures. All incidents need to be rapidly resolved and used as examples to reinforce procedures.

Social Impact Table 49 (Map 49C) (KPs 910.63 – 924.6): Goksun Plain, Kahramanmaras Province

concerned about the security of the pipeline. • ***Local opinion of construction camp:*** A construction camp would be welcomed and construction camp workers would be welcome in the settlement. • ***Perceived benefits of construction camp:*** women believe they will be able to sell fruit and vegetables to workers, in addition local residents are hopeful that the highway will be widened and speed limits implemented to reduce traffic accidents. • ***Perceived problems of construction camp:*** none • ***Settlement livelihood:*** both agriculture (sugar beat, sunflowers, beans, vegetables and fruit) and animal husbandry: bovine-milk. In Gumgum, trade and transport are an important source of livelihood. In Camkipru there is a store in the industrial district, and an oil station near the highway. • ***Accessibility:*** both settlements have good accessibility as they are close to the highway. • ***Infrastructure:*** good water supply in both settlements, however, there are frequent water cuts in both settlements. No sewerage system in Gumgum, and neither settlement receives mobile phone coverage. • ***Services:*** there is a small grocery shop and a picnic area in Camkopru. Four trucks and a tractor in Gumgum and a truck and a tractor in Camkopru. • ***Skills:*** unskilled workforce in both settlements. One local resident in Gumgum has a heavy truck driver's licence, and there is a drilling operator in Camkopru.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock.	BTC Company to look at opportunities to cooperate in providing **health awareness training** **Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be	**Low likelihood of significant health impacts.** **Benefits** from raising health awareness of workforce (many of whom are local). Further positive benefits dependent on scale of social investment activities. Continued attention to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of

Goksun (C) (S)			
• ***Demographics:*** 36,247inhabitants with 10,000 households. There has been an increase in population. • ***Safety:*** settlement is situated 2km from pipeline and 1km from the nearest house. • ***Health:*** poor sewerage system with health implications. • ***Project attitude:*** generally positive. • **Local opinion of construction camp:** the majority of inhabitants would welcome it. • ***Perceived benefits of construction camp:*** yes • ***Perceived problems of construction camp:*** none. • ***Land ownership & use:*** local residents privately own 60% of land and lease a further 25%. Use of seasonal irrigation. Bee keeping. There is seasonal grazing. • ***Settlement livelihood:*** agriculture (wheat, sugar beat, sun flowers and animal feed); animal husbandry (bovine-milk); trade and transportation; bee keeping and fishing (many trout farms) are the main sources of livelihood. Milk collected from local residents and sent to Nigde for processing. • **Availability & skills:** skilled & unskilled workforce, one heavy truck and many smaller trucks and minibuses in the district. 51% of respondents would be willing to accept a temporary job.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc ***Skills*** Increased opportunity to provide skilled or semi-skilled labour or to source	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **Potential positive benefits** to local settlements.

Social Impact Table 49 (Map 49C) (KPs 910.63 – 924.6): Goksun Plain, Kahramanmaras Province

• ***Accessibility:*** the settlement is accessible, there will be a two-way 17km long road, and an asphalted 8km road constructed around the district to enhance transportation and accessibility. Goksun is located at the crossroads of other provinces and is therefore very busy. • ***Information provision:*** 70% of the population is literate. Best local information provision mechanisms: newspapers and family members. • ***Infrastructure:*** piped water is supplied to households and businesses. There is regularity of water supply and no alternative water source. There are problems with the sewerage system. • ***Services:*** there is phone, mobile coverage, good electricity supply, coffee houses, shops, library, market, post office, bank, police, transport, sports facilities. There is a primary school and a health centre, with a doctor and a midwife. • ***Other settlement services (of potential use to construction workers):*** Two bank branches, ATM, many markets, coffee shops and a post office. • ***Settlement problems:*** lack of water, unemployment, education, poor sewage system and drought.	goods or materials **Fishing** Potential reduction in fisheries yield or damage to fisheries habitats within 2km downstream of a river crossing.	given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints. **Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	***RESIDUAL IMPACTS***
Yeni Mah (L) (T)			
• ***Demographics:*** 2,300 inhabitants, there is no migration. • ***Safety:*** settlement centre is 6km from pipeline. • ***Project attitude:*** according to the Muhtar a construction camp would be welcome. People are concerned about land costs. • ***Land ownership & use:*** 90% of land is privately owned by local residents. There is no seasonal grazing. There is use of seasonal irrigation. Agriculture, hunting, construction, transport, trade and education are the main sources of livelihood. • ***Accessibility:*** the settlement is accessible all year. • ***Information provision:*** Turkish speaking settlement. Population is 80% literate. The best information provision mechanisms are	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Environmental Impact Table 50 (Maps 50A and 50B) (KPs 924.6 – 940.8): Goksun Plain and the Armutyucesi Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils types from the previous section continue in this section of the route: • Mesic Fine-silty Xerorthents in irrigated valley soils. • Mesic Coarse-silty Xerorthents where headlands begin to encroach on the valley. • Mesic Coarse-loamy Shallow Dystric Xerochrepts near southern headlands.	Main potential impacts: • soil productivity; • sediment yield; • channel alteration; • soil contamination; • waterlogging.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Time construction to avoid irrigation periods. Allow soils time to drain. Use equipment mats as required.	**MINOR IMPACT** Soil productivity losses are predicted to last less than 3 months after construction is completed. In areas where waterlogging occurs, water is predicted to remain in surface depressions for less than 3 months after construction.
Landscape and Visual			
The route continues through the irrigated agricultural landscape before ascending over smooth ridge through mixed forests, and then along the side of a 10km long upland valley. The valley sides and the steeper slopes of the pale limestone mountains beyond are covered in juniper scrub and Cedar of Lebanon, while Meryemcilbeli Creek meanders through green water-meadows strewn with buttercups in the flat valley bottom. The landscape sensitivity of the valley is moderate to high, although the presence of an electricity transmission line along the valley detracts from views. Visibility is also restricted by the terrain.	Although construction will not take place in the wet meadows along Meryemcilbeli Creek, access from the adjacent road has the potential to cause visual impact.	• Replant disturbed woodlots, field boundary forests, and riparian forests. • Reinstatement of the BTC Pipeline. • Access from the main highway across the river valley will be restricted to the absolute minimum of crossing points and vehicle movements will be carefully controlled. • Moveable equipment mats will be used on the wet soils to spread vehicle weight and avoid deep rutting.	**MODERATE IMPACTS** The wet meadows/ marshland in the valley will show the scar of construction traffic, but if undertaken with care and sensitivity, this will last no more than a year or two. Some loss of juniper scrub, and residual impacts arising from thin stony soils limiting the success of reinstatement will result in longer-term/permanent visual effects. Minor impacts elsewhere.
Groundwater			
The pipeline route continues to pass over the Goksun Plain (unconfined	Potential for moderate and	Apply standard mitigation	**MINOR IMPACT**

Environmental Impact Table 50 (Maps 50A and 50B) (KPs 924.6 – 940.8): Goksun Plain and the Armutyucesi Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
aquifer) for c. 5.2km at the beginning of this section. Water samples taken from the unconfined aquifer at Well Site No. 14, (DSI 42035-A: Sirapinar Well), c. 880m west of route (KPs 924.0 – 925.2) indicate groundwater quality is Class II.	localised impacts to groundwater quality from construction activities.	measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including: • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	With the application of the specified mitigation measures described, only minor impacts are expected to occur, which will be short-term in nature.
Ecology			
Important Ecological Factors ESA 42 is identified between KP 936.8 and KP 938.5 for the globally-threatened plant species (*Gentiana boissieri*). The IUCN status for this species is given in Table 5.20, Section 5. ESA 43 begins at the end of this map (KP 940.0) and continues on to the next map (see Environmental Impact Table 51 and Map 51B for species description). Two nationally-threatened bird species were recorded along this route section – 1 Barred Warbler at KP 929.6 and 1 Northern Goshawk at KP 935.3. The protection status for these species are given in Table 5.21, Section 5.	Destruction of habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 42 & 43. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1: • remove and keep top soil and sub-soil separate, protect top	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April,

Environmental Impact Table 50 (Maps 50A and 50B) (KPs 924.6 – 940.8): Goksun Plain and the Armutyucesi Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Shrubs, thickets and dense vegetation along the RoW will be cleared outside the breeding season for the Barred Warbler. Preconstruction survey will establish the presence of potential Northern Goshawk nest sites within the RoW. If nesting sites are identified, avoidance of construction activity from April to July.	and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.

Social Impact Table 50 (Map 50C) (KPs 924.6 – 940.8): Goksun Plain and the Armutyucesi Mountain Area, Kahramanmaras Province

MAP 50: PROJECT INFORMATION			
There are no pump stations, construction camps or block valve stations in the area.			
MAP 50: MAP HIGHLIGHTS			
• Land use includes irrigated agriculture, rain fed agriculture, non agricultural land and pasture. • Forests cover slopes east and west of the valley. • The pipeline crosses the Osungele creek and the Degirmendere irrigation pond. • A National highway passes through this section, but does not cross the pipeline corridor.			
MAP 50: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** three settlements will be directly impacted by the pipeline project; all of these (Findikli Koyak, Kucuk Camurlu, Degirmendere) have land intersected by the proposed pipeline (L); no settlements are within 5km of a pump station or construction camp (P/C) and no settlements are within 500m of the pipeline route (D). Settlements impacted by traffic have not yet been identified. One settlement is downstream of a river/creek pipeline crossing (Degirmendere is downstream of Osungele creek) (R). • ***Surveyed:*** two settlements (Findikli Koyak, Degirmendere) were surveyed in the field (S). One settlement (Kucuk Camurlu) was surveyed on the telephone (T).			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	***RESIDUAL IMPACTS***
Findikli Koyak (L) **(S)**			
• ***Demographics:*** 950 with 135 households. There has been a recent decrease in population. • ***Safety:*** the centre of settlement is situated 2.25km from the pipeline, the nearest house in settlement is situated 1.9km from the pipeline. • ***Project attitude:*** the community is not hostile to the pipeline and are eager to receive expropriation payments for land with low yields. They would also welcome a construction camp. • ***Land ownership & use:*** 72% of land is communally owned, and 24% is privately owned. There is seasonal grazing in April, October and November. Seasonal irrigation is not used. • ***Settlement livelihood:*** agriculture, bee keeping, construction, transport, trade and education are the main sources of livelihood. • ***Availability & skills:*** machine operator, vehicle driver, driver and	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in expropriation process. ***Skills***	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **See Overview of Land Acquisition Process in Appendix C9.**	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of Land Acquisition Process in Appendix C9.**

Social Impact Table 50 (Map 50C) (KPs 924.6 – 940.8): Goksun Plain and the Armutyucesi Mountain Area, Kahramanmaras Province

welders are present. 73% of inhabitants are willing to accept temporary jobs. • ***Accessibility:*** the settlement is accessible and is 10km from the district centre. • ***Information provision:*** 100% of the population is literate. The local sources of information are newspaper, family members and the Muhtar. • ***Environmental & cultural sites:*** Roman and Byzantine ruins, military buildings • ***Infrastructure:*** piped water is available although the supply is not regular. There is no alternative water source. • ***Services:*** phone, mobile systems, market, sports facilities, transport and a primary school are present. • ***Settlement problems:*** lack of water, state support in agriculture and animal husbandry and lack of a sewage system.	Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials ***Special Sites*** Refer to Environmental Impact Tables.	**Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints.	**Potential positive benefits** to local settlements
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	***RESIDUAL IMPACTS***
Degirmendere (L) (R) (S)			
• ***Demographics:*** 4,500 inhabitants with 510 households. There is no change in population. • ***Safety:*** the centre of the settlement is situated 1.5km from pipeline. Nearest house in the settlement is 1km from the pipeline. • ***Project attitude:*** the community is not hostile to the pipeline. Expectations that it may create employment. A majority of the people would welcome a construction camp. • ***Land ownership & use:*** 45% of land is privately owned and used by local residents, 30% is share cropped. Many parcels of land are owned by the State but cultivated by farmers without the title deeds. Sunflowers, wheat barley and sugar beet are cultivated. Seasonal irrigation is used. • ***Settlement livelihood:*** agriculture, hunting and local government are the main sources of livelihood.	***Conflict over land boundaries*** Exacerbation of existing conflicts ***Construction hazards: animals*** Trench poses safety hazard for livestock	**Land boundaries to remain clearly demarcated** at all times. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock.	**No significant residual impacts** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 50 (Map 50C) (KPs 924.6 – 940.8): Goksun Plain and the Armutyucesi Mountain Area, Kahramanmaras Province

• ***Available Skills:*** machine operators, vehicle drivers, drivers and welders are available. 73% will accept a temporary job. • ***Accessibility:*** the settlement is accessible from March to December and is 13km from the district centre. • ***Information provision:*** 85% of the population is literate. Best local source of information is family etc. • ***Environmental & cultural sites:*** Roman and Byzantine ruins present in and around the settlement. Military buildings and caves. • ***Infrastructure:*** piped water is available although the supply is irregular. There is no alternative water source. • ***Services:*** phone, mobile, electricity network, coffee houses, shops, transport and sport facilities. There are three schools, one high school and two elementary schools. There is a Health Centre, with one doctor and one midwife. • ***Settlement problems:*** transport difficulties and unemployment.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Hunting*** Temporary reduction in game due to disturbance during construction. ***Accessibility to recruitment*** Decreased access to recruitment process ***Special sites*** Refer to Environmental Impact Tables.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Significance cannot be established** at this time **No residual impact expected**

Social Impact Table 50 (Map 50C) (KPs 924.6 – 940.8): Goksun Plain and the Armutyucesi Mountain Area, Kahramanmaras Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	*RESIDUAL IMPACTS*
Kucuk Camurlu (L) (T)			
• ***Demographics:*** 1,020 inhabitants, there is 15% migration. • ***Safety:*** the centre of the settlement is situated 3km from the pipeline. The nearest house is 2.2km from the pipeline. • ***Project attitude:*** local residents would generally welcome a construction camp. There are no major concerns regarding the project. • ***Land ownership:*** 80% of land owned is communal. • ***Settlement livelihood:*** agriculture, bee keeping (two households for their own consumption) and construction are the main activities. • ***Accessibility:*** settlement is inaccessible from December to February. The distance from settlement to district centre is 19km. • ***Information provision:*** The literacy rate is 90%. Key sources of local information are the telephone and television. • ***Environmental & cultural sites:*** mausoleum, forest. • ***Infrastructure:*** piped water, no regularity of water supply. Alternative source is a stream. • ***Settlement problems:*** Inadequate access, watering canals must be rearranged and unemployment.	***Land*** Potential complications in expropriation process. ***Accessibility of recruitment*** Decreased access to recruitment process. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**See Overview of Land Acquisition Process in Appendix C9.** Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during	**See Overview of Land Acquisition Process in Appendix C9.** **No residual impact expected** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 50 (Map 50C) (KPs 924.6 – 940.8): Goksun Plain and the Armutyucesi Mountain Area, Kahramanmaras Province

		construction.	

Environmental Impact Table 51 (Maps 51A and 51B) (KPs 940.8 – 962.3): Kayranlik Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Mesic Fine-silty Xerorthents in irrigated valleys. • Mesic Coarse-silty Xerorthents where headlands encroach on valleys. • Mesic Coarse-loamy or Loamy-skeletal Shallow Dystric Xerochrepts on stony uplands. • Mesic Coarse-silty Xerorthents on lower slopes adjoining valley. • Rock outcrops. The pressure reduction station (IPT1) will be located at KP 951.4.	Main potential impacts include: • soil erosion; • soil productivity; • sediment yield; • channel alteration; • potential for existing soil contamination at the IPT1 site; • waterlogging.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Reforestation. • Time construction to avoid irrigation periods. Allow soils to drain. Use equipment mats as required. • A soil survey of the IPT1 site will be undertaken prior to construction activities commencing to identify areas of existing contamination.	**MINOR IMPACT** Soil erosion predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.
Landscape and Visual			
The route continues along the side of the upland valley whose sides and the steeper slopes of the pale limestone mountains beyond are covered in juniper scrub and Cedar of Lebanon. The small river continues to meander through green water meadows strewn with buttercups in the flood plain. At the southern end in particular, landscape sensitivity is very high. The limestone mountains have eroded into huge rounded blocks and the first of the Black Pine forests, characteristic of the Taurus mountains, appear.	Impacts likely to be locally significant although visibility limited by terrain. Although construction will not take place in the wet meadows along the river, access from the main route has the potential to cause visual	• Apply 'Soils' reinstatement specifications above. • Access from the main highway across the river valley will be restricted to the absolute minimum of crossing points and vehicle movements will be carefully controlled.	**MODERATE IMPACT** The wet meadows/ marshland in the valley will show the scar of construction traffic, but if undertaken with care and sensitivity, this will last no more than a year or two.

Environmental Impact Table 51 (Maps 51A and 51B) (KPs 940.8 – 962.3): Kayranlik Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Here the river diverges, plunging down a steep rocky gully, while the route descends sharply past the medieval Meryemcil Castle and into the irrigated valley of the Karapinar around Geben. The route skirts west of the town through the head of an intensively farmed and irrigated basin. It then climbs again into another scenically attractive area of pine forest-clad mountains, over a pass at 1,730m asl, and down again along the valley of the Karapinar Creek past broad-leaved trees and bushes. The route then cuts southwestwards again through more pine-clad mountains up to 1,600m asl before descending very sharply into a broad flat-bottomed valley. IPT1 will be located within cultivated land and will require a permanent landtake of approximately 3.17ha. In addition, there will be a temporary campsite during the construction period, which will occupy 3.49ha and will lie c. 1km from IPT1. The IPT1 site occupies a flat valley c. 3.5km south-west of the settlement of Geben and c. 8.6km north-east of the settlement of Cokak; at an altitude of c. 1,300m. BVS-048 will be located at KP 943.2 within cultivated land. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to c. 125m in length.	impact. Construction will open a straight, narrow avenue through dense scenic forest. Most views during pipeline construction will be within a short distance of the construction works although longer distance views will be possible from the tops of some of the surrounding hills. Potential impacts and their management during BVS construction will be the same as those during pipeline construction.	• Moveable equipment mats will be used on the wet soils to spread vehicle weight and avoid deep rutting. IPT1 has been located within the rural environment to minimise its impact on residential properties. In general IPT1 will be visible over a smaller distance than the four pump stations due to the smaller size of the facility and its location in a valley surrounded on most sides by hills. The site terrain at IPT1 is generally flat so landform screening will generally be inappropriate. Indigenous and locally characteristic trees and scrubs will form the landscaping planting scheme. More detailed measures to reduce potential landscape and visual impacts will be developed in conjunction with detailed design and construction planning.	Some loss of juniper scrub, and residual impacts arising from thin stony soils limiting the success of reinstatement will result in longer-lasting/permanent visual effects. Conspicuous visual impact in highly scenic area, but unlikely to have much more adverse effect than a firebreak. **MINOR IMPACT** Due to the remote location of IPT1, there are no high sensitivity residential viewers that will experience views of the site during construction. In addition, although, recreational users in the vicinity of IPT1 are considered to be moderately sensitive viewers, the site will be visible over a relatively small area during construction.. This impact will be localised and will occur only in the short-term during construction (see Section 7.2.2 for an assessment of operational landscape and visual impacts).

Environmental Impact Table 51 (Maps 51A and 51B) (KPs 940.8 – 962.3): Kayranlik Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Surface Geology and Geohazards			
Faults The route crosses Cokak Fault at KP 960.2. Cokak Fault is part of a complex and only partly understood system of faults in the Taurus Mountains. It is a reverse/right-lateral fault, c. 3km long, thought to be connected with the Kiziloluk fault, forming a longer structure of c. 15-20km. The main fault has 14 fault planes distributed over a zone 8m wide with four subsidiary splays identified across an area of 700m.	See *Section 8*.	See *Section 8*.	See *Section 8*.
Surface Waters			
The Geben Reservoir is currently under construction to the east of the route between KPs 943.8 – 945.7. It will have reservoir volume of 14,700,000m³ and will provide irrigation water to an area of c. 3,530ha. The reservoir will receive flows from Meryemcil Creek, which is crossed by the pipeline route c. 1.25km downstream of the reservoir.	Potential for indirect disturbance at Geben Reservoir, due to run-off containing suspended solids from working areas resulting in a reduction in water quality in the pond. Potential for short-term sedimentation and turbidity.	Apply standard mitigation measures in Section 6.4 and the RP, Appendix C2, to control sedimentation and turbidity in Meryemcil Creek, such as sediment filters/trapping devices, settling ponds and trench de-watering. However, this impact will not be transmitted as far as the reservoir.	**MINOR IMPACT** Disturbance will be limited to the immediate working area of Meryemcil Creek. Sedimentation of Meryemcil Creek will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Ecology			
Important Ecological Factors ESA 43 continues from the previous map and is identified between KP 940.0 (see Map 50B) and KP 943.8 for eight globally-threatened plant species (*Verbascum luridifolium, Alkanna cappadocia, Tanacetum haradjanii, Allium tauricola, Gentiana boisseri, Helianthemum antitauricum, Erodium micropetalutum* and *Galium antitaurica*). The IUCN status for these species are given in Table 5.20, Section 5. ESA 44 occurs between KP 955.9 and KP 961.0 and is identified for eight globally-threatened plant species (*Thlaspi cilicicum, Centaurea antitauri, Cephalanthera kotschyana, Corydalis solida sp. tauricola, Johrenia silenoides, Cyclamen pseudo-ibericum, Chionodoxa forbesii* and *Bupleurum zoharii*). In addition, one globally-threatened plant (*Verbascum luridifolium*) occurs just outside the corridor south-east of KP 960.2. The	Habitat destruction of maquis, mixed forest, and habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to the Dipper, nationally-threatened bird, during nesting, feeding or indirectly, through habitat loss if construction is undertaken	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 43 and 44. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if	**MODERATE IMPACT** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). . **MINOR IMPACTS** at most for breeding birds, where pipeline

Environmental Impact Table 51 (Maps 51A and 51B) (KPs 940.8 – 962.3): Kayranlik Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
IUCN status for these species are given in Table 5.20, Section 5. At KP 953.7, 1 Dipper (nationally-threatened) was recorded. The protection status for these species are given in Table 5.21, Section 5. Grey Wolf was recorded at KP 948, KP 955.1 and near KP 960.2. This species is not globally-threatened and has no protection in Turkey, although it is protected under CITES, the Bern Convention and the EU Habitats Directive. At KP 949.6, Golden Jackal (nationally-threatened) was recorded. Globally-threatened mammals were recorded at KP 953.7, (Mehely's Horseshoe Bat, Forest Dormouse, Caucasian Squirrel). The protection status for these species are given in Table 5.21, Section 5.	during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods. Minor temporary disturbances are expected to globally-threatened mammals during seasonal sensitivities (see EMMP, Appendix C1): • the Mehely's Horseshoe Bat gives birth in late spring and hibernates in hollow trees, ruins, tunnels, garrets or caves from September/October to spring (May). • breeding season for the Forest Dormouse is between May and August, but in warmer areas the season may extend beyond this period. Potential for minor temporary impacts to wolves as hunting of this species is permitted in Turkey. However, this species is nomadic during spring and summer, which are the optimum months during which pipeline construction is likely to occur.	the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Preconstruction surveys will establish whether suitable Dipper nesting sites are available within 250m of the Karapinar Creek crossing. If this is the case, construction activity is to be avoided between April and July. Preconstruction surveys during the summer months will establish the presence and abundance of Mehely's Horseshoe Bat and seek to identify summer colonies and potential winter hibernation roosts. Hollow trees within the RoW of the Pipeline will be removed during the late summer months to prevent their use as winter	construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACT** at most to globally-threatened mammals during the construction period where the specified mitigation measures are applied for the seasonal sensitivities identified for each species. **MINOR IMPACTS** at most for wolves with the application of the specified mitigation measures.

Environmental Impact Table 51 (Maps 51A and 51B) (KPs 940.8 – 962.3): Kayranlik Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		roosting sites and to allow construction to continue during the autumn, winter and early spring periods. Caves, ruins or underground cavities, which have been identified as hibernation roosts (particularly those close to camps and works sites), will be secured, and placed out of bounds, to avoid their disturbance by workers. Preconstruction surveys for the Forest Dormouse of dense woodland in the RoW; if present route clearance will be undertaken during the autumn or winter period. In areas where the presence of wolves has been confirmed, education of workers to be alert and aware of the potential for interactions will include refuse management on sites (particularly where construction camps are located). Furthermore, workers must not wander alone in areas where wolves may be present, especially at night. The hunting of wolves or any other wildlife by the BTC Project personnel or contractors will be strictly forbidden and rigorously enforced.	

Environmental Impact Table 51 (Maps 51A and 51B) (KPs 940.8 – 962.3): Kayranlik Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Archaeology and Cultural Heritage			
The route passes through the archaeological site of Meryemcil Castle (1st Degree Site - registered by the MoC) north of KP 945. The majority of the castle ruins are still standing and a tumulus lies to the north of the castle. The MoC have given this site larger boundaries than previously identified during field surveys. The site has been proposed for registration by the preservation council	Meryemcil Castle will potentially experience structural damage during pipeline construction. Other potential impacts will include vibration. In addition, indirect impacts may arise from construction activities that will affect the visual/historical setting of the site	The extent of Meryemcil Castle will be investigated during further field surveys prior to construction. This will determine the need for detailed surface research and/or rescue excavations at this site. Further investigation will delineate this site and identify a safe route through. Specific mitigation to be developed following site investigations. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ If blasting is required, then it will be conducted in such a way that it does not pose a threat to the integrity of buildings still standing on the site. To avoid vibration impacts, percussive piling will be not allowed within 100m of the site.	**MODERATE TO MINOR IMPACTS** Residual impacts cannot be determined precisely for this site at this stage since the extent is unknown. Archaeological investigations prior to construction will establish the full extent of the site. However as investigations are expected to find a safe route through the site, the ultimate scale of impact is likely to be minor and short-term in duration.

Social Impact Table 51 (Map 51C) (KPs 940.8 – 962.3): Kayranlik Mountain Area, Kahramanmaras Province,

MAP 51: PROJECT INFORMATION

A pressure reduction station (IPT1) will be located on a relatively flat 3.17ha site surrounded by mountainous terrain. It is privately owned land 3.5km south-west of Geben settlement. A temporary construction camp (3.49ha) will be located 1km south-west of IPT1. There will also be a block valve station in the area.

MAP 51: MAP HIGHLIGHTS

- Land use includes irrigated agriculture, rainfed agriculture, non-agricultural land and pasture.
- The pipeline crosses the Karapinar Creek, the Koyunyolu Creek and the Geben Dam.
- Fairly dense forests and shrub land.
- The route passes close to foot of the hill of Meryemcil Castle, the majority of the castle ruins are still standing and a tumulus lies north of the castle.

MAP 51: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** two settlements are impacted by the pipeline (Geben and Cokak), both have land intersected by the pipeline (L) and are within 5km of a pump station (P). The centre of one settlement (Cokak) is within 1km of the pipeline (D). No settlements are within 2km of the block valve station (B). Settlements impacted by traffic have not been identified. One settlement is downstream of a creek crossing (Geben is downstream of the Koyunyolu creek) it is also downstream of the Geben Dam intersected by the pipeline (R).

- ***Surveyed:*** one settlement (Geben) was surveyed via telephone (T), one settlement (Cokak) was surveyed in the field (S).

- ***Disclosure Meeting Location***: Geben

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Geben Municipality (L) (P) (R) (T)			
• ***Demographics:*** 7,250 inhabitants, 8% of population migrates. 350 households (Camili Quarter); 375 households (Bogazici Quarter). No winter migration. • ***Safety:*** the centre of settlement is situated 1.5km from pipeline. Nearest house situated 750m from pipeline. Distance to pressure reduction station is 2.5km. Centre of Camili Mah is situated 300m from the pipeline, and the nearest house is 25m from the pipeline. • ***Project attitude:*** The pressure reduction station is welcome, as would be a construction camp. There are no major concerns regarding the project.	**PRESSURE REDUCTION STATION IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction of the pressure reduction station. See Sections 6 and 7 and the Overview of Land Acquisition Process in		

• ***Pressure reduction station land ownership:*** state land, which is not currently being used. • ***Perceived benefits of pressure reduction station:*** access to employment opportunities, possible upgrading of roads, increased settlement incomes. • ***Perceived problems of pressure reduction station:*** concern that construction of the pipeline could damage lands, water canals, creeks, rivers and settlement infrastructure. • ***Land ownership & use:*** the settlement owns 40% of land, and 40% is communal land. 66% of households have legal land titles. The average land holding is 2.9ha incorporating 5 plots. 78% of households own or cultivate land. Primary land use is grain, 66% of the households surveyed undertake irrigation, primary livestock is cattle, and seasonal grazing is undertaken. • ***Settlement livelihood:*** agriculture, bee keeping (two households), manufacturing, transport, trade, education. • ***Accessibility:*** the settlement is accessible all year. It is 27km from settlement to the local district centre. There are two roads from the settlement to the pressure reduction station: Goksun road, which is commonly used by local residents and another which travels between cultivated land directly from the Camili. • ***Information provision:*** 60% of the population is literate. Local information sources are TV and newspaper. Within the Camili and Bogazici quarters of the settlement, there is a 100% literacy rate. • ***Environmental & cultural sites:*** castle, plateau. • ***Infrastructure:*** piped water is available. There is regularity of water supply. There is no alternative water source. In the Camili and Bogazici quarters, there is electricity, medium standard of water supply, a settlement dump, and a good telecommunications system but no mobile phone coverage. • ***Settlement problems:*** inadequate access to water, unemployment. • ***Other:*** as the pressure reduction station is located within a valley and surrounded by forest, it is not visible from Geben. • ***Health:*** in the Camili and Bogazici quarters, there is poor nutrition, poor sanitary conditions, insufficient health care services and poverty.	Appendix C9. **PIPELINE IMPACTS:** ***Irrigation*** Potential loss of flow from planned/accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc **Specific to the Camili and Bogazici quarters of Geben:** ***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low. **Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in expropriation process.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. **See Overview of Land Acquisition Process in Appendix C9.**	**Any additional damage to be compensated for.** **Potential for accidents involving livestock. .** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of Land Acquisition Process in Appendix C9.**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Cokak (L) (P) (D) (S)			
• ***Demographics:*** 520 inhabitants with 340 households, winter migration occurs. There has been an increase in population. • ***Safety:*** the centre of the settlement is situated 1km from pipeline and 8.4km from the pressure reduction station. The nearest house is 750m from the pipeline. • ***Project attitude:*** generally positive, although there is some concern over the potential interruption to agricultural activities, damage to infrastructure and land, and possibility of increased traffic through the settlement. • ***Local opinion of pressure reduction station:*** welcome • ***Perceived pressure reduction station benefits:*** employment at IPT1 and in pipeline construction. Extra income.	**PRESSURE REDUCTION STATION IMPACTS:** The settlement will be a primary receptor of impacts resulting from construction of the pressure reduction station. See Sections 6 and 7 and the Overview of Land Acquisition Process in Appendix C9.		

• ***Pump station land ownership:*** State land that is not used. • General land ownership & use: state owned (10%). • ***Settlement livelihood:*** agriculture (grain, vegetables and fruit trees); hunting, forestry, seasonal construction, transport, trade and education. • ***Accessibility:*** adequate road quality, distance to from settlement to local district centre is 18km • ***Information provision:*** The literacy rate is 99%. • ***Information provision mechanisms:*** radio and television. • ***Infrastructure:*** piped water is available, however, there is no regularity of water supply. Local streams provide an alternative water source. There is an electricity service and good telecommunications. • ***Services:*** there is a Health Centre, a travelling health team, travelling midwife and a primary school. • ***Settlement problems:*** financial problems, unemployment.	**PIPELINE IMPACTS:** ***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Forests*** Loss of a resource used by settlements. Increased expenditure on other fuel sources.	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement. **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.

		width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	**Significance cannot be established at this time**
	Hunting Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Accessibility to recruitment Decreased access to recruitment process	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**

Environmental Impact Table 52 (Maps 52A and 52B) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Rock outcrops • Mesic Coarse-loamy or Loamy-skeletal Shallow Dystric Xerochrepts on stony uplands • Mesic Coarse-silty Xerorthents on valley locations.	Main potential impacts include: • soil erosion; • sediment yield; • channel alteration; • soil productivity; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Reforestation.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
Mixed segments of undulating, rolling, hilly, and steeply dissected terrain provide a transition between the Taurus Mountains and foothills north of the Cukurova plain. The route passes along a broad flat-bottomed valley used primarily for mixed crops but retaining a significant cover of broad-leaved trees. Landscape sensitivities are moderate along this valley where the hay fields and arable crops together with the trees along the river form a soft landscape that contrasts with the stony valley slopes and the dark brooding angular forms of the mountains beyond.	Mostly short-term construction modifications of landscape although greater impacts associated with tree loss.	Full reinstatement of the BTC Pipeline. Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** Small loss of trees along riverbanks and in hedgerows and copses.
Surface Geology and Geohazards			
Faults Route crosses the Kiziloluk Fault near KP 963.9, which forms part of a complex and poorly understood system of faults in the Taurus Mountains. This fault is c. 12 – 17 km long and c. 3 m wide, forming the southeastern boundary of the Cokak Plane basin. It is a class B fault and believed with to be connected to the Cokak 2 Fault.	See *Section 8*.	See *Section 8*.	See *Section 8*.
Ecology			
Important Ecological Factors			**MODERATE IMPACT**

Environmental Impact Table 52 (Maps 52A and 52B) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
ESA 45 continues from the previous map and occurs between KP 962.1 and KP 964.3. This ESA is identified for the globally-threatened plant species (*Grammosciadium confertum*). In addition, two globally-threatened plants (*Helianthemum antitauricum* and *Tanacetum haradjanii*) occur just outside the corridor north of Akifiye settlement. The IUCN status for these species are given in Table 5.20, Section 5. ESA 46 commences on this map at KP 974.5 and continues on to the next map (see Map 53B) until KP 981.6. This ESA is identified for twelve globally-threatened plant species (*Lamium garganicum sp. nepetifolium, Verbascum hadschinense, Kundmannia syriaca, Corydalis solida spp. tauricola, Sideritis cilicica, Chionodoxa forbesii, Bupleurum zoharii, Trifolium rousseanum, Silene inclinata, Cephalanthera kotschyana, Micromeria cremnophila sp. amana* and *Allium tchihatschewii*). The IUCN status for these species are given in Table 5.20, Section 5. At KP 965, Blasius' Horseshoe Bat, Caucasian Squirrel (both globally-threatened) and Eurasian Badger were recorded. The protection status for these species are given in Table 5.21, Section 5.	Destruction of habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Minor temporary disturbances are expected to globally-threatened mammals during seasonal sensitivities (see EMMP, Appendix C1): • the Blasius' Horseshoe Bat gives birth in late spring and hibernates in colonies of up to 300 individuals in ruins, caves or cavities from September/October to spring (May). The main threat to the Caucasian Squirrel is through illegal hunting.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESAs 45 and 46. Diligence will be exercised in searching inside the corridor for those species known to occur just outside of the construction corridor. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Preconstruction surveys during the summer months will establish the presence and abundance of the species and seek to identify	Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACT** at most to globally-threatened Mehely's Horseshoe Bat during the construction period where the specified mitigation measures are applied for the seasonal sensitivities identified. **MINOR IMPACTS** at most for Caucasian Squirrel with the application of the specified mitigation measures.

Environmental Impact Table 52 (Maps 52A and 52B) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		summer colonies and potential winter hibernation roosts. Hollow trees within the RoW of the pipeline route will be removed during the late summer months to prevent their use as winter roosting sites and to allow construction to continue during the autumn, winter and early spring periods. Caves, ruins or underground cavities, that have been identified as hibernation roosts (particularly those close to camps and works sites), will be secured and placed out of bounds to avoid their disturbance by workers.	
Noise			
Altinboga settlement in Andirin District is located c. 182m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Altinboga settlement during soil stripping activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings;	**MINOR IMPACT** Short-term noise impacts are expected to occur during soil stripping. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.

Environmental Impact Table 52 (Maps 52A and 52B) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		• existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	

Social Impact Table 52 (Map 52C) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

MAP 52: PROJECT INFORMATION

There are no pump stations, or construction camps or block valve stations in this area.

MAP 52: MAP HIGHLIGHTS

- Major land use is irrigated agriculture with some rainfed agriculture, forests and shrubberies.
- Many of the hills are classified as rubble land.
- The Karasu Creek runs within the pipeline corridor.
- The pipeline crosses an energy transmission line.

MAP 52: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** three settlements will be directly impacted by the pipeline project (Akifiye, Orhaniye, Altinboga). They will each have land intersected by the pipeline (L), two of them are within 500m of the pipeline (Akifiye, Altinboga), (D), none are within 5km of a pump station (P), or within 2km of a block valve station (B). Settlements impacted by traffic have not been studied. Two settlements are downstream of a river/creek crossing (Kiziloluk and Altinboga are downstream of a creek).

- ***Surveyed:*** one settlement (Akifiye) was surveyed in the field (S). Two settlements (Orhaniye, Altinboga) were surveyed via telephone (T).
- ***Not surveyed:*** two settlements were not surveyed, Kiziloluk (1.25km from the pipeline) and Karanebili (1.5km from the pipeline).
- ***Not on the map:*** Orhaniye.
- ***Disclosure Meeting Location:*** Altinboga

SITESPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Akifiye (L) (P) (D) (S)			
• ***Demographics:*** 500 inhabitants with 110 households. There has been a decrease in population. • ***Safety:*** the centre of settlement is situated 500m from the pipeline. The nearest house is 75m from the pipeline. • ***Health:*** malnutrition was raised as a major problem. • ***Project attitude:*** there is no hostility towards the pipeline. The majority of local residents would welcome a construction camp. • ***Land ownership & use:*** 85% is privately owned and used by the settlement. There is seasonal grazing. Seasonal irrigation is used. • ***Conflict over land rights & ownership:*** land has been fragmented essentially through inheritance without completing the transfer	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 52 (Map 52C) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

essentially through inheritance without completing the transfer formalities with the land registry. Also the sale of land to seasonal visitors causes problems where they are made without proper legal documents, these sales also cause further fragmentation of land. • ***Settlement livelihood:*** agriculture, animal breeding, fishing, forestry, construction, trade, tourism and land sales are the main sources of livelihood. Maize, chickpea, wheat, barley, clover are cultivated. • ***Availability & skills:*** five out of 24 construction skills. 82% of inhabitants are willing to accept temporary jobs. • ***Accessibility:*** the settlement is accessible all year and is 14km from the district centre. • ***Information provision:*** 98% of the population is literate. Local sources of information are family members and the Muhtar. • ***Infrastructure:*** piped water is available. There is no regularity of water supply. There is no alternative water source. • ***Services:*** phone, coffee houses, market, transport and sports facilities are available. There is a school and a midwife. • ***Settlement problems:*** no sewage system, poor water supply to houses at high altitudes, infertile soil, leading to only one harvest per year and no formal garbage collection.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Forests*** Loss of a resource used by settlements. Increased expenditure on other fuel sources. ***Conflict over land*** Exacerbation of existing conflicts ***Land*** Potential complications in expropriation process.	settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure. **Land boundaries to remain clearly demarcated** at all times. **See Overview of Land Acquisition Process in**	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement. **No significant residual impacts** **See Overview of Land Acquisition Process in Appendix C9**

Social Impact Table 52 (Map 52C) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

		Appendix C9	
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Orhaniye (L) **(T)**			
• ***Demographics:*** 275 inhabitants with no seasonal migration. • ***Safety:*** the centre of the settlement is situated 1.6km from pipeline. • ***Project attitude:*** according to the Muhtar a construction camp would be welcome and there are no major concerns regarding the pipeline. • ***Land ownership:*** 40% of land is owned by local residents. 40% is communal land. There is seasonal grazing. • ***Settlement livelihood:*** agriculture, bee keeping, forestry, construction, transport, trade and education are the main sources of livelihood. • ***Accessibility:*** the settlement is not accessible throughout the year.	***Construction hazards: animals*** Trench poses safety hazard for livestock ***Land*** Potential complications in	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **See Overview of Land Acquisition Process in**	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of Land Acquisition Process in**

Social Impact Table 52 (Map 52C) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

• ***Information provision:*** 60% of the population is literate. The main source of information is television. • ***Environmental & cultural sites:*** 'healthy' water. • ***Infrastructure:*** piped water, no regularity of water supply. A settlement fountain is an alternative source. • ***Settlement problems:*** inadequate access to water, inadequate healthcare and inaccessibility.	expropriation process. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Appendix C9** **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low. ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**Appendix C9** **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 52 (Map 52C) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Altinboga (L) (D) (T)			
• ***Demographics:*** 200 inhabitants with 50% migration. • ***Safety:*** the centre of the settlement is situated 400m from the pipeline. The nearest house is 150m from the pipeline. • ***Project attitude:*** the attitude is generally very positive, but inhabitants need more information on the pipeline. Majority of local residents would welcome a construction camp. • ***Land ownership & uses:*** 90% of land is owned by the settlement. There is seasonal grazing. Seasonal irrigation is used. • ***Settlement livelihood:*** agriculture, bee keeping (10 families), fishing (99 families own consumption), forestry, construction and education are the main sources of livelihood. Key crops are millet, wheat and barley. • ***Accessibility:*** the settlement is accessible throughout the year and is 6km from the district centre. • ***Information provision:*** 90% of the population is literate. Local sources of information are television and newspapers. • ***Environmental & cultural sites:*** graveyard, plateau. • ***Infrastructure:*** no piped water is available. There is no regularity of water supply. The alternative water source is the local spring. • ***Services:*** a telephone network has been set up, but no connection is available yet. Electricity network available. • ***Settlement problems:*** no sewage system is available and no drinking water network.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage to be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts**

Social Impact Table 52 (Map 52C) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Forests Loss of a resource used by settlements. Increased expenditure on other fuel sources.	If a significant number of trees on forestry land are cut, discuss with settlement & appropriate authorities to identify **acceptable compensation.** The level of compensation will be facilitated by the Projects complaints procedure.	**Significant impact** where more than 10% of trees are cut on forestry land used by any one settlement.

Social Impact Table 52 (Map 52C) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

	Fishing Potential reduction in fisheries yield or damage to fisheries habitats within 2 km downstream of a river crossing.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.
	Irrigation Potential for loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected.**

Social Impact Table 52 (Map 52C) (KPs 962.3 – 977.0): Tril Mountain Area, Kahramanmaras Province

	Drinking water Potential for disruption or contamination of drinking water during construction.	The need for an **alternative source of water** will be evaluated prior to construction, and if necessary will be provided by the Project.	**No residual impact.**

Environmental Impact Table 53 (Maps 53A and 53B) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils types from the previous section continue in this section of the route: • Rock outcrops. • Mesic Coarse-loamy or Loamy-skeletal Shallow Dystric Xerochrepts on stony uplands. • Mesic Coarse-silty Xerorthents on valley locations.	Main potential impacts include: • soil erosion; • sediment yield; • channel alteration; • soil productivity; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Reforestation.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
The route descends around the eastern edge of Andirin, a small mountain market town at 1,000m asl, and then again descends sharply down hillsides clothed in trees and bushes with small terraced fields, the greenery of these south-facing slopes now reflecting the humid influence of the Mediterranean Sea. Further south, the landscape sensitivities are generally moderate. The diverse terrain provides visual interest but with some diminution in quality where the forests have been felled and replaced by juniper scrub and maquis on the thin limestone soils between the jagged rocky outcrops.	Some loss of trees and bushes from field boundaries and in denser areas of maquis. Short-term construction modifications of landscape.	Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** Small loss of trees and bushes along field boundaries and in denser areas of maquis.
Ecology			
Important Ecological Factors ESA 46 continues on this map for c. 11km (see Environmental Impact Table 52 and Map 52B for description of species and mitigation measures to be applied in this ESA). BVS-049 will be located at KP 977.7 on cultivated land within ESA 46. Approximately 350m^2 of permanent landtake required. A new access road will be constructed of c. 35m in length.	Permanent loss of plain steppe habitat during construction at BVS-049 within ESA 46. Minor temporary disturbance	Prior to construction of BVS-049, a site specific survey will be undertaken by an ecological specialist to identify and locate threatened species at the site and at any surrounding areas	**MINOR IMPACT** Based on the mitigation measures described, the small area of habitat affected and the temporary nature of construction activities, it is predicted that only minor

Environmental Impact Table 53 (Maps 53A and 53B) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
At KP 981.5, Grey Wolf was recorded. At KP 982.7, Striped Hyena (globally-threatened) was recorded. Approximately 350m west of the Pipeline at KP 985.0, the Mediterranean Horseshoe Bat (globally-threatened) was recorded. The protection status for these species are given in Table 5.21, Section 5.	to globally-threatened bat during seasonal sensitivities (see the EMMP, Appendix C1): • breeding and hibernation periods for globally-threatened bat species, from September to May. Potential for minor temporary impacts to wolves as hunting of this species is permitted in Turkey. However, this species is nomadic during spring and summer, which are the optimum months during which pipeline construction is likely to occur. Although, the globally-threatened Striped Hyena has no legal protection in Turkey, hunting of this species may pose a potential impact.	potentially affected by construction activities. Based on the findings of this survey, appropriate mitigation will be determined. The area of sensitive habitat in ESA 46 affected by construction activities will be minimised to the minimum necessary for safe working. Preconstruction bat surveys during the summer months will establish the presence and abundance of the species and seek to identify summer colonies and potential winter hibernation roosts. Hollow trees within the RoW of the pipeline route will be removed during the late summer months, under the close supervision of an ecologist approved by BOTAŞ, to prevent their use as winter roosting sites and to allow construction to continue during the autumn, winter and early spring periods. Caves, ruins or underground cavities, that have been identified as hibernation roosts (particularly those close to camps and works sites), will be secured and placed out of bounds to avoid their disturbance by workers. In areas where the presence of	impacts on the biological environment will occur as a result of construction activities at BVS-049. This assessment will be confirmed by the site-specific survey prior to construction. **MINOR IMPACTS** at most to the globally-threatened Mediterranean Horseshoe Bat during the construction period where the specified mitigation measures are applied for the seasonal sensitivities identified. **MINOR IMPACTS** at most for the Striped Hyena and the Grey Wolf with the application of the specified mitigation measures.

Environmental Impact Table 53 (Maps 53A and 53B) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		the Striped Hyena and Grey Wolf has been confirmed, the hunting of these mammals or any other wildlife by the BTC Project personnel or contractors will be strictly forbidden and rigorously enforced. Furthermore, workers must not wander alone in areas where wolves may be present, especially at night. The hunting of either mammal or of any other wildlife by the BTC Project personnel or contractors will be strictly forbidden and rigorously enforced, since correct identification of protected species cannot be guaranteed.	
Noise			
The following noise sensitive receptors have been identified: • Kastal settlement located c. 99m from the centreline and a provincial highway crossing; • Ahetli settlement, located c. 150m from the Pipeline; • Yahyalar settlement located c. 252m from the Pipeline and a provincial highway crossing. Blasting works will also be required adjacent to Kastal settlement, located c. 99m from the pipeline route.	Noise impacts are expected to occur at Ahetli settlement during soil stripping and welding/lowering activities. Kastal settlement will experience noise impacts during soil stripping, welding/lowering and backfilling, and during excavation and pilling works associated with the highway crossing. Blasting will also give rise to noise and vibration at Kastal	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings;	**MAJOR IMPACT** Noise impacts are predicted to occur to outlying dwellings in Kastal settlement during soil stripping, welding/lowering, backfilling and piling operations. In addition, vibration impacts are expected to occur during piling. Stockpiling of spoil, where possible, and mobile noise barriers, will be used to screen nearby dwellings from construction works to the maximum extent possible. However, those nearest may

Environmental Impact Table 53 (Maps 53A and 53B) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	settlement. Yahyalar settlement will also experience noise impacts during piling works associated with a highway crossing.	• existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	still be exposed to temporary construction noise levels that exceed 70dB(A). It is important to emphasise this is a cautious assessment. The construction programme will make provision for a further assessment based on the true numbers of receptors affected and separation distances of receptors from noise sources and take whatever actions are necessary to reduce impacts to an acceptable level. Noise and vibration impacts are also expected to occur during blasting at Kastal settlement. Although this may give rise to annoyance to residents, it is unlikely to cause structural damage to buildings. The Contractor will carry out detailed noise and vibration predictions once the specific blasting methods have been developed. The proposed method of working and mitigation measures will be agreed with the relevant authorities in advance of works taking place. Residents

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
			will also be notified in advance of works involving blasting. **MINOR IMPACT** Noise impacts are also predicted to occur to outlying dwellings at Yahyalar settlement during piling and at Ahetli settlement during soil stripping and welding/lowering.
Archaeology and Cultural Heritage			
Minnetpinari (3rd Degree Site*) – flat settlement located to south-east of the Pipeline within the 100m Corridor. No architectural remains have been discovered on the surface. * This site has not yet been registered by the MoC and is provisionally assigned this classification. The site has been proposed for registration by the preservation council	Potential for site to experience direct impacts, such as ground disturbance, during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of the site.	Minnetpinari will be fenced throughout the construction period to avoid accidental damage. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MINOR IMPACT** Assuming Minnetpinari is fenced, impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Social Impact Table 53 (Maps 53C) (KPs 977.0 – 992.6):

MAP 53: PROJECT INFORMATION			
There is a primary construction camp (Lot C) in the area. It is located on 16.74ha of unregistered pastureland (Refer also to May 49). There is also a block valve station in the area.			
MAP 53: MAP HIGHLIGHTS			
• Major land use is non-agricultural land, general shrubbery. • The route passes through a narrow canyon, through which flow minor streams. • The pipeline crosses a National highway and an unclassified road.			
MAP 53: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** 25 settlements will be directly impacted by the pipeline project. 12 settlements (Yesilyurt, Yenimahalle, Tufanpasa, Cicekli, Altinoluk, Cokceli, Basdogan, Torun, Haciveliusagi, Tokmakli, Kesim, Kumarli) will have land intersected by the pipeline (L) (C). Six settlements (Ahetil Mah, Andirin, Kesim, Kumarli, Tokmakli, Altinoluk) are within 500m of the pipeline (D). None are within 2km of the block valve station (B). Settlements impacted by traffic have not been identified. No settlements are downstream of a river/creek crossing. • ***Surveyed:*** seven settlements were surveyed in the field (S) (Andirin, Cokceli, Kumarli, Buyukpinar, Eleker, Karaduldular). Nine settlements were surveyed via telephone (T). • ***Not surveyed:*** Ahetil Mah (500m from the pipeline), Karataslik (1.9km from the pipeline), Yesilyurt, Torun, Karaduldular, Hacimirza, Aliclibucak, Koccakoz. • ***Not on map:*** Yenimahalle, Torun, Buyukpinar, Karadurdular, Elekler, Hacimirza, Ortatepe, Aliclibucak, Koccakoz. • ***Disclosure Meeting Location:*** Kesim			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Buyukpinar (C) **(S)**			
• ***Demographics:*** 16 inhabitants with three households. It is a sector of Caglayan settlement. • ***Distance of proposed camp to nearest house:*** 1km • ***Distance of proposed camp to nearest land plot:*** the proposed camp area includes some land of the local residents. • ***Camp site land ownership:*** private land with legal title. No share cropping. • ***Project attitude:*** positive. • ***Local opinion of construction camp:*** generally welcoming. The settlement welcomes construction workers into their settlement	***Construction camp Impacts*** The settlement will be a primary receptor of impacts resulting from construction workers	**Monthly community liaison** meetings will be held. **Preferential employment** opportunities. **Project to liase** with local health authorities. BTC Company to look at	**Low likelihood of significant impacts.** Potential for impacts arising from breaches of rules and procedures. All incidents will be rapidly resolved and used as examples to reinforce procedures.

Social Impact Table 53 (Maps 53C) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

settlement welcomes construction workers into their settlement. • ***Perceived benefits of construction camp:*** employment opportunities in the camp and pipeline construction, increased settlement income and the opportunity to provide indirect services such as milk to camp workers. • ***Perceived problems of construction camp:*** none. • ***Settlement livelihood: agriculture:*** wheat & barley (subsistence & sale), sugar beat (sale), animal feed (subsistence) and vegetables (subsistence); animal husbandry: cattle (subsistence & sale) and poultry (subsistence). There is grazing from April to October. More than 50% of the land is irrigated. • ***Skills:*** one car available for use by construction workers only. • ***Accessibility:*** poor quality road, that is not accessible for short periods of time in winter months (December to January). • ***Infrastructure:*** no piped water, instead local residents use a common settlement well. Regular electricity supply, no sewerage system, telephone system but no mobile coverage. • ***Services:*** no market or shop, there are no schools. • ***Information provision:*** of the female population only one woman is literate. The main information sources: TV, radio, family, friends & neighbours • ***Settlement problems:*** unemployment, low income, poor sewerage system and insufficient water supply for the land.		opportunities to cooperate in providing **health awareness training**	**Low likelihood of significant health impacts**. **Benefits** from raising health awareness of workforce (many of whom are local). Further positive benefits dependent on scale of social investment activities.
	Construction hazards: humans Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from awareness raising. **Additional damage to be compensated for.**
	Construction hazards: animals Trench poses safety hazard for livestock.	**Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be

Social Impact Table 53 (Maps 53C) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

		for livestock.	facilitated by the Projects complaints procedure.
	Drinking water Potential for disruption or contamination of drinking water during construction	The need for an **alternative source of water** will be evaluated prior to construction, and if necessary will be provided by the project.	***No residual impact***
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility to information Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc.	**Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low.	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.
	Accessibility to recruitment Decreased access to recruitment process.	Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**No residual impact expected**

	of flow from spills or increase in sedimentation. ***Hunting*** Temporary reduction in game due to disturbance during construction.	Project to **establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	unexpected loss of flow, affected land-users will be compensated. **Significance cannot be established at this time.**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Kumarli (L) (D) (S)			
• ***Demographics:*** 670 inhabitants with 135 households, there has been an increase in population over the past five years. • ***Safety:*** the centre of settlement is situated 1.5km from pipeline. The nearest house 70m from pipeline. • ***Project attitude:*** there is no hostility towards the pipeline, however, there are some concerns about recently purchased vacant land, which will be intersected by the pipeline. A construction camp would be welcome. • ***Land ownership & use:*** 85% of the land is privately owned, 7% is share cropping, seasonal grazing in April, May, Summer, October, November. Land is heavily fragmented and without title deeds. Use of seasonal irrigation. • ***Settlement livelihood:*** agriculture, bee keeping, fishing, trade and local government are the main sources of livelihood. Key crops are	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500 m of construction work.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 53 (Maps 53C) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

grain, vegetables, fruit trees, cotton. • ***Availability & skills:*** machinery operator, vehicle driver, 46% of respondents are willing to take on a temporary job. • ***Accessibility:*** the settlement is accessible all year round and is 22km from the district centre. • ***Literacy:*** 90% of the population is literate. Local information source is family. • ***Infrastructure:*** piped water is available. There is no regularity of water supply. There is a no alternative water source. • ***Services:*** phone, mobile, coffee houses, shops, sports facilities and a primary school. • ***Settlement problems:*** lack of water, education, bad settlement roads, dust and insufficient health facilities.	Land beyond that compensated for may be affected if mitigation measures not fully implemented.	**Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected.	**Any additional damage to be compensated for.**
	Construction hazards: animals Trench poses safety hazard for livestock	**Livestock crossings** will be established at locations agreed with the community. **Stock poof fencing** will be erected in areas of danger for livestock.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.
	Conflict over land Exacerbation of existing conflicts.	**Land boundaries to remain clearly demarcated** at all times. **Temporary fences** will be erected where there is a separation of more than one day between work teams.	**No significant residual impacts.**
	Bees Disturbance of any stationary hives located within 300m of the route.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure.

Social Impact Table 53 (Maps 53C) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

	Fishing Potential reduction in fisheries yield or damage to fisheries habitats **if** within 2 km downstream of a river crossing.	**Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure.	**No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.
	Sensitive vegetation used by bees Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
	Accessibility to information Sectors of the population may not have access to	**Communication with settlement** must take into account settlement characteristics to ensure	**Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will

Social Impact Table 53 (Maps 53C) (KPs 977.0 – 992.6): North of Andirin Settlement to Ahetli Settlement, Kahramanmaras Province

	project related information on employment opportunities, potential disruption to utilities, etc. ***Accessibility to recruitment*** Decreased access to recruitment process.	equal access to information for all residents. This should include using appropriate channels of communication and media. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	keep this to a minimum. **No residual impact expected.**

Environmental Impact Table 54 (Maps 54A and 54B) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/Osmaniye Province border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Rock outcrops. • Mesic Coarse-loamy or Loamy-skeletal Shallow Dystric Xerochrepts on stony uplands. • Mesic Coarse-silty Xerorthents on valley locations. • Mesic Fine-silty Xerorthents in irrigated valleys. • Mesic Coarse-silty Xerorthents where uplands encroach on valleys. • Thermic Orthic Calcixerolls (commonly truncated on steep slopes).	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity. Other potential impacts include: • channel alteration; • waterlogging; • soil contamination.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation - see typical drawings. • Reforestation. • Time construction to avoid irrigation periods. Allow soils to drain. Use equipment mats as required.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.
Landscape and Visual			
The route emerges onto the plain at the northern end of the Aslantas Barrage Lake and turns westwards crossing the fast-flowing and clear waters of the Kesis River (a tributary that feeds the lake). A steep limestone canyon with high scenic value lies just upstream of the crossing point. The route then travels west and south across the much gentler rounded, and more heavily populated landscapes of the Taurus foothills to Kadirli, a mixture of rolling rain-fed agricultural land, olive groves, and heavily-wooded gullies of moderate to low sensitivity. The Aslantas National Park, designated partly for its high landscape value, lies to the south of the route here, but the route is too distant to have any visual impact on this.	Formation of conspicuous whitish line across landscape if pale-coloured marl is exposed. May be long-term or permanent where difficult to re-instate, or where ecological considerations prevent application of fertiliser. Otherwise short-term construction modifications of landscape components.	Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** Exposed marl may retain its whitish colour and show as a white line across the landscape. However, landscape fairly resilient to impact. Some loss of trees and bushes along river banks, field boundaries, and patches of maquis.
Surface Waters			
Kesis River channel is sinuous with a trapezoidal cross-section and pool	Direct disturbance to bank	Apply standard mitigation	**MINOR IMPACT**

Environmental Impact Table 54 (Maps 54A and 54B) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/Osmaniye Province border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
and riffle bars. Width of crossing is 30m, with a bank-full width of >13m and no floodplain. Bed consists of cobbles and boulders and the flow is perennial, of a pool and riffle type at low flows. High flows drown out pool and riffle sequence and the flow becomes uniform and rapid or steep and tumbling. Bank-side vegetation comprises deciduous trees and truncated bars lying c. 5 – 6m above the channel are managed for cereals, hay and other crops. Water samples taken c. 250m downstream of the crossing point indicate that this is a Class III river. Cebicli Quarter and Aslantas Dam/reservoir are both downstream of the crossing point.	and bed morphology through physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Water quality indicates that Kesis River is polluted and further degradation in quality will be avoided. Potential for medium-term sedimentation and turbidity. There will be no impact to the water quality in Aslantas Reservoir.	measures in Section 6.4 and the RP, Appendix C2, for the protection of surface waters, Including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench.	Disturbance will be short-term and limited to the immediate working area. Sedimentation of Kesis River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Ecology			
Important Ecological Factors ESA 47 is identified between KP 994.3 and KP 997.7 for the globally-threatened plant species (*Ophrys reinholdii spp. leucotaenia*). This species is classified by the World Conservation Union (IUCN) as Endangered (defined as: Taxa in danger of extinction and whose survival is unlikely if the causal factors continue operating), and is the rarest plant in global terms to be found along the route. The IUCN status for these species are given in Table 5.20, Section 5. At KP 1002.35 1 Barred Warbler and 1 Black Francolin (both nationally-threatened) were recorded and another Black Francolin was recorded at KP 1003.68. The protection status for these species are given in Table 5.21, Section 5. Approximately 80m west of the route near KP 1016.5, Mehely's Horseshoe Bat, Schreiber's Long-fingered Bat, (both globally-threatened) and the Striped Hyena were recorded. The protection status for these species are given in Table 5.21, Section 5.	Habitat destruction of maquis and habitats peripheral to cultivated land may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 47. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the

Environmental Impact Table 54 (Maps 54A and 54B) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/Osmaniye Province border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
At KP 995.7, Common Tortoise (globally-threatened), also known as the Asia Minor Spur-thighed Tortoise, was recorded. The protection status for this species is given in Table 5.21, Section 5. BVS-050 will be located at KP 994.8 on cultivated land within ESA 47. Approximately 350m^2 of permanent landtake required. A new access road will be constructed of c. 45m in length.	Minor temporary disturbance to globally-threatened bat species during seasonal sensitivities (see the EMMP, Appendix C1): • the Mehely's Horseshoe Bat gives birth in late spring and hibernates in hollow trees, ruins, tunnels, garrets or caves from September/October to spring (May). • the Schreiber's Long-Fingered bat gives birth to young from October – November; and hibernates in cold climates or curtails activity in cold weather between September/October and spring in hollow trees, ruins or caves). This species also migrates up to 200km between summer and winter retreats. The globally-threatened Striped Hyena has no legal protection in Turkey, and therefore hunting of this species may pose a potential impact. Potential temporary disturbance to the Asia Minor	sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during re-instatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 47. Shrubs, thickets and dense vegetation along the RoW will be cleared outside the breeding season for the Barred Warbler. Clearance of trees, shrubs and thickets in advance of the construction to be undertaken outside the April – July period for the Black Francolin. Preconstruction surveys for the both bat species during the summer months will establish the presence and abundance of the species and seek to identify summer colonies and potential winter hibernation roosts. Hollow trees within the RoW of the Pipeline will be removed during the late summer months to prevent their use as winter roosting sites and to allow	RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACT** at most to a globally-threatened bat species during the construction period where the specified mitigation measures are applied for the seasonal sensitivities identified. **MINOR IMPACTS** at most for the Striped Hyena with the application of the specified mitigation measures. **MINOR IMPACTS** only to the globally-threatened Common Tortoise, where the specified mitigation measures identified for the seasonal sensitivity are applied during the construction period. **MINOR IMPACT** Based on the mitigation measures described, the small area of habitat affected and the temporary nature of construction activities, it is predicted that only minor

Environmental Impact Table 54 (Maps 54A and 54B) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/Osmaniye Province border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	Spur-thighed Tortoise during its identified seasonal sensitivity. This species lays eggs in scoops and hollows in the earth, with eggs (up to 12 per clutch) laid in May-June and hatchlings emerge from August to September. Hibernation is between October/November and March/April. Permanent loss of plain steppe habitat at the BVS-050 site within ESA 47.	construction to continue during the autumn, winter and early spring periods. Caves, ruins or underground cavities, which have been identified as hibernation roosts (particularly those close to camps and works sites), will be secured, and placed out of bounds, to avoid their disturbance by workers. In areas where the presence of the Striped Hyena has been confirmed, the hunting of this mammals or any other wildlife by the BTC Project personnel or contractors will be strictly forbidden and rigorously enforced. Preconstruction surveys to establish locations and population densities of tortoises. Mature individuals and hatchings will be translocated to appropriate habitats in advance of construction. In areas of known concentrations, construction activities will be avoided during the May-September period. Prior to construction of BVS-050, a site specific survey will be undertaken by an ecological specialist to identify and locate	impacts on the biological environment will occur as a result of construction activities at BVS-050. This assessment will be confirmed by the site-specific survey prior to construction

Environmental Impact Table 54 (Maps 54A and 54B) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/Osmaniye Province border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		threatened species at the site and at any surrounding areas potentially affected by construction activities. Based on the findings of this survey, appropriate mitigation will be determined. The area of sensitive habitat in ESA 47 affected by construction activities will be minimised to the minimum necessary for safe working.	
Noise			
Cebicli settlement is located c. 188m from the centreline of the Pipeline.	Short-term noise impacts are expected to occur at Cebicli settlement during soil stripping activities.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the	**MINOR IMPACT** Noise impacts are expected to occur during soil stripping activities, as it may not be possible to utilise spoil to screen dwellings from the works. Noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days.

Environmental Impact Table 54 (Maps 54A and 54B) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/Osmaniye Province border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		use of mobile noise barriers for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	
Archaeology and Cultural Heritage			
There are three archaeological sites in this section located within the 100m Corridor: • Oren Dosu (3rd Degree Site – registered by the MoC) – a flat settlement, dating back to the Roman period, located to the north of the pipeline route. The settlement is totally destroyed and only the column supports are visible. The graveyard is covered with trees. • Urlu Cemetery (1st Degree Site*) is on the edge of the 100m Corridor and the site dates back to the Ottoman Period. • Catak Mevkii (Ruin-1), (2nd Degree Site*), – a graveyard dating back to the Ottoman period, located on the Catak ridge and overlooking the Hancerli Dere Valley. The pipeline route will now cross this site as a result of a previous route change to avoid a landslide area. * These sites have not yet been registered by the MoC and are provisionally assigned these classifications. Urlu Graveyard and Ruin 1 (Çatak location) have been proposed for Registration by the preservation council	Potential for direct impacts, such as ground disturbance, at all two sites during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of these sites.	Oren Dosu is avoided through re-routing of the Pipeline. However, the site will also be fenced throughout the construction period, as the route will still pass close to it. Urlu Cemetery will be fenced throughout the construction period to avoid accidental damage. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ. If blasting is required, then it will be conducted in such a way that it does not pose a threat to the integrity of the column supports still standing on the site. To avoid vibration impacts, percussive piling will be not allowed within 100m of Oren Dosu.	**MINOR IMPACT** Assuming Oren Dosu and Urlu Cemetery sites are fenced, impacts will be limited to the temporary disturbance of the setting of the sites and peripheral features.

Osmaniye Socio-Economic Overview

Demographics:
Osmaniye is the fourth smallest of the pipeline provinces with a population of 438,000, of whom only 3% live in the pipeline corridor. The average household size is six (corresponding with the survey average). Urban areas are relatively stable, whereas rural areas experience out-migration. Osmaniye is in a state of transition and is recognised as a developing province. All survey respondents are Sunni Muslim. Turkish is the primary language. Kurdish and Circasian are spoken by a small percentage of respondents as a second language.

Land:
Land is primarily privately owned, followed by State ownership. Land is relatively evenly distributed and 82% of surveyed respondents (the second highest of the surveyed provinces) are involved in agriculture and own, or cultivate land. Agricultural activities are the main source of income, with grain being the main output. The province is primarily situated on the Cukurova plain, the most fertile area of Turkey, with land usually cultivated twice a year. Animal husbandry is generally carried out for subsistence purposes. Some mountain settlements are relatively isolated, they are located in the Taurus Mountains, have scattered housing, and are referred to as '*forest settlements'*. Irrigation is used by some of these settlements.

Livelihoods:
Osmaniye is ranked the lowest (tenth) of the survey provinces in terms of average household income and also has a low ranking for combined income and assets (eg wealth). It is the only surveyed southern province with limited agricultural and industrial diversification. Non-agricultural activities are limited and trade is difficult in the forest settlements.

Infrastructure & Services:
All surveyed settlements along the pipeline corridor have access to grid electricity, telecommunications and water infrastructure. However, electricity supply is irregular (and insufficient for heating) and drinking water is reportedly often polluted, therefore local residents depend on imported water tanks for drinking water.
Sewerage infrastructure is lacking. The average literacy rate is 84% for the surveyed population (literacy rates drop amongst elder women) and Osmaniye exhibits the second highest percentage of surveyed inhabitants with primary school education (54%) and secondary education (21%). Only 1% of respondents had attained a university level education.

Key Problems:
Erosion is a problem for 'forest settlements', although the most frequently raised settlement problems were: unemployment and low income; insufficient sewerage or irrigation infrastructure, poor roads and poor access to clean water.

Project Attitude:
Surveyed settlements generally perceive the project positively and have high expectations for employment. They have some reservations regarding risks associated with the project such as damage to roads and traffic during harvest periods. 5% of respondents are particularly concerned about noise and dust from construction activities.

Social Impact Table 54 (Map 54C) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/ Osmaniye Province border

MAP 54: PROJECT INFORMATION

There are no pump stations or construction camps in the area. There is one block valve station.

MAP 54: MAP HIGHLIGHTS

- Land use: rain fed agriculture, shrubs, forest and irrigated agriculture.
- Most of the route follows the summit of a ridge, bound east and west by small streams.
- There is an energy transmission line that bisects the pipeline
- The pipeline traverses through two rivers, the Kesis River and the Anditin River, which lead to the Aslantas Dam.
- Unclassified roads link local settlements and the pipeline crosses a provincial highway twice.

MAP 54: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** three settlements will be directly impacted by the pipeline project, one (Kesim) has land intersected (L) by the proposed pipeline; and two (Tokmakli and Cebicli) are within 500m of the pipeline route (D) and Tokmakli is within 2km of the block valve station. None of the settlements are within 5km of a pump station. Settlements impacted by traffic have not yet been identified. Two settlements are located within 2km down stream of a pipeline river crossing; Tokmakli is on the Andirin River, 1km downstream of the pipeline; and Cebicli is located 500m downstream of the Kesis river pipeline crossing. (R).

- ***Surveyed:*** Bektasli was surveyed in the field (S) and one settlement (Kesim) was surveyed by telephone (T).
- ***Not surveyed:*** Cebicli (200m from the pipeline), Tokmakil (250m from the pipeline), Baktasli (750m from the pipeline).

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Kesim (L) (T)			
• ***Demographics:*** 465 inhabitants although experiencing a decrease in population levels. No seasonal migration. • ***Safety:*** the nearest house is 75m from the pipeline and the settlement centre is 500m from the pipeline. • ***Project attitude:*** the local residents are generally aware of the Project and the Muhtar is of the opinion that they would welcome a construction camp and have no major hostilities towards the pipeline. • ***Land ownership & use:*** 75% of land is owned by local residents. There is no seasonal grazing of livestock and no fishing activities are undertaken. Bee-keeping takes place, with honey consumed by the	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 54 (Map 54C) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/ Osmaniye Province border

undertaken. Bee-keeping takes place, with honey consumed by the households. Hunting is carried out by local residents. Seasonal irrigation channels are used. • ***Settlement livelihood:*** agriculture, bee keeping and hunting, construction are main activities. 90% of respondents are family labourers. Local residents have had previous construction experience eg the Tefken project. • ***Accessibility:*** 19 km from the district centre. No accessibility problems during winter. • ***Information provision:*** according to the Muhtar, all local residents speak Turkish and are literate. TV is the most important source for both local and national information. • ***Infrastructure:*** no piped water. An artesian well is the main water source. • ***Settlement problems:*** unemployment and inadequate access to water.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Sensitivity to vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Protective barrier fencing** will be erected where a settlement is within 500 m of construction work. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300 meters from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be	**Any additional damage will be compensated for.** **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 54 (Map 54C) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/ Osmaniye Province border

		discussed at meetings before and during construction.	
	Hunting Temporary reduction in game due to disturbance during construction.	**Project to establish level of hunting** in settlements prior to construction. Where hunting is a source of subsistence (rather than recreation), appropriate mitigation measures and compensation needs to be agreed. The level of compensation will be facilitated by the Projects complaints procedure.	**Significance cannot be established at this time**
	Irrigation Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	If irrigation water is disrupted longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be **compensated**.
	Drinking water Potential for disruption or contamination of drinking water during construction.	The need for an **alternative source of water** will be evaluated prior to construction, and if necessary will be provided by the Project.	**No residual impact.**

Social Impact Table 54 (Map 54C) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/ Osmaniye Province border

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Bektasli (S)			
• ***Demographics:*** 315 inhabitants with 60 households. • ***Safety:*** settlement is situated 1.75km from pipeline. • ***Project attitude:*** no hostility towards the pipeline. There are some fears about the pipeline damaging the drinking water resources and lines, roads and telephone lines. Concerns about expropriation of land, and the effect of the pipeline on their crops. A construction camp would be welcome. • ***Land ownership & use:*** 85% of land is owned and used by the local residents, 10% of land is rented from others and used by local residents, 5% is communal land. There is seasonal grazing of livestock in April, Summer, October, November. There are no disagreements amongst local residents. Some land is registered under the name of deceased persons causing concern over land titles and compensation. Use of seasonal irrigation. • ***Settlement livelihood:*** agriculture and bee keeping. Key crops are sugar beet and cotton. • ***Availability & skills:*** machine operators, vehicle driver and drivers. 64% of respondents are willing to take on temporary jobs. • ***Accessibility:*** the settlement is not accessible all year round and is 20km from the district centre. • ***Information provision:*** 100% of the population is literate. Local source of information is the family. • ***Environmental & cultural sites:*** civilian architecture, military buildings • ***Infrastructure:*** piped water is not available. There is no regularity of water supply. There is a common depot as an alternative water source. • ***Services:*** phone, mobile, sewage system available, electricity infrastructure, market, transport and a school. • ***Settlement problems:*** lack of water and problems with quality of water,	***Irrigation*** Potential for loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc. ***Accessibility to recruitment*** Decreased access to recruitment process.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **No residual impact expected.**

Social Impact Table 54 (Map 54C) (KPs 992.6 – 1016.8): West of Andirin River and North of Tokmakli Settlement to West of Atlantis Reservoir, Kahramanmaras/ Osmaniye Province border

• unemployment, insufficient health facilities and lack of a sewage system.			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Kesim (L) (D) (T)			
• ***Demographics:*** 420 inhabitants with no seasonal migration. • ***Safety:*** the centre of settlement is situated 600m from pipeline. • ***Project attitude:*** according to the Muhtar there are no major concerns. A construction camp would be welcome. • ***Land ownership & use:*** 70% of land is privately owned. No seasonal grazing is undertaken. Use of seasonal irrigation. • ***Settlement livelihood:*** agriculture, trade, local government. • ***Settlement accessibility:*** the settlement is not accessible, the distance from the settlement to the district centre is 15km. • ***Information provision:*** 100% of the population is literate. • ***Environmental & cultural sites:*** plateau • ***Infrastructure:*** piped water is available. There is regularity of water supply. There is a no alternative water source. • ***Settlement problems:*** unemployment.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.

Environmental Impact Table 55 (Maps 55A and 55B) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Thermic Orthic Calcixerolls (commonly truncated on steep slopes). • Thermic Sandy Orthic Quartzipsamments.	Main potential impacts include: • soil erosion; • sediment yield; • soil productivity. Other potential impacts include: • channel alteration; • waterlogging.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation – see typical drawings. • Reforestation. Co-ordinate construction with farmers. Avoid construction on freshly irrigated soils: allow them to drain. Use equipment mats as required.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.
Landscape and Visual			
The route travels south-west across gentle, rounded, and more heavily populated landscapes of the Taurus foothills, a mixture of rolling rain-fed agricultural land, olive groves, and heavily wooded gullies. It crosses some dissected and hilly terrain made up of heavily eroded, thick beds of white marl interbedded with sandstone conglomerate. Numerous narrow, flat-bottomed stream channels adjoin moderately steep and steep slopes leading to gently rounded summits cloaked in broad-leaved woodland and maquis. Fields congregate about summits, on flood plains, and on gently sloping land; woodlands and maquis occupy steep wastelands North of the settlement of Kaniagali, the route finally emerges onto the	Formation of conspicuous whitish line across landscape if pale-coloured marl is exposed. Likely to be less conspicuous here than elsewhere since agricultural activities will camouflage it. Short-term construction modifications of landscape components.	Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** Agricultural landscape is considered resilient to change. Therefore, only minor impacts are expected.

Environmental Impact Table 55 (Maps 55A and 55B) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Cukurova Plain (c.40m asl), a wide, sweeping, flat plain, immensely fertile and largely turned over to irrigated arable agriculture. Landscapes in the northern part are expansive and mostly featureless - endless fields of cereals with occasional scattered trees or small copses interrupted sporadically by large or small irrigation canals. At this point it is less than 3km away from the Karatepe Aslantas National Park, designated partly for its high landscape value, but the route is too distant to have any visual impact upon this. Landscape sensitivities along the route are low. BVS-051 will be located at KP 1029.7 on cultivated land. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 30m in length.	Potential impacts and their management during BVS construction will be the same as those during pipeline construction.		
Groundwater			
The route passes over the Cukurova (Adana-Ceyhan) Plain, which is an unconfined aquifer, for c. 2.6km at the end of this section. The dominant aquifer type is unconfined with a thickness of 100m. The groundwater quality in this zone is poor due to seawater intrusion.	Potential for moderate and localised impacts to groundwater quality from construction activities.	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including: • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	**MINOR IMPACT** With the application of the specified mitigation measures described, only minor impacts are expected to occur, which will be short-term in nature.
Ecology			
Important Ecological Factors ESA 48 is identified between KP 1026.5 and KP 1028.5 for four globally-threatened plant species (*Ophrys transhyrcana spp. amanensis, Centaurea calcitrapa spp. cilicica, Centaurea lycopifolia* and *Anthemis pungens*). The IUCN status for these species are given in Table 5.20, Section 5.	Habitat destruction of maquis or areas peripheral to cultivated lands may result in the loss of individuals from	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 48. The feasibility of	**MODERATE IMPACTS** Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction

Environmental Impact Table 55 (Maps 55A and 55B) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
At KP 1022.4, 1 Black Francolin (nationally-threatened) was recorded. The protection status for this species is given in Table 5.21, Section 5.	populations of globally-threatened plants. Potential for direct disturbance to a nationally-threatened bird during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods.	translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Clearance of trees, shrubs and thickets in advance of the construction to be undertaken outside the April – July period for the Black Francolin.	planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for a nationally-threatened breeding bird, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW.
Noise			
Hourly measurements were taken at Kaniagali Quarter of Cigcik Settlement (L_{eq} value of 60.5 dBA), which may have been slightly higher than expected due to windy conditions at the time of survey. Kaniagali is located c.200m from the pipeline centreline.	Short-term noise impacts are expected to occur at Kaniagali during soil stripping.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that	**MINOR IMPACT** Short-term noise impacts are expected to occur during soil stripping activities, as it may not be possible to utilise spoil to screen dwellings from the works. Noise impacts are

Environmental Impact Table 55 (Maps 55A and 55B) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	likely to occur. However, this will be short-term in nature, lasting only for a few days.
Archaeology and Cultural Heritage			
The old settlement of Karagedik Area lies to the east of the Pipeline on the edge of the 100m Corridor. This Medieval settlement has been totally destroyed. The MoC has not yet registered the site. Karagedik area has been proposed for registration by the regional preservation council	Potential for direct impacts, such as ground disturbance, at this site during pipeline construction. Indirect impacts may arise from construction activities that will affect the	The pipeline has been re-routed to avoid the old settlement of Karagedik. Potential impacts will therefore be avoided. Construction will be carried out under the supervision of an archaeologist authorised BOTAŞ.	**MINOR IMPACT** Impacts will be limited to the temporary disturbance of the site setting and peripheral features.

Environmental Impact Table 55 (Maps 55A and 55B) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

	visual/historical setting of the site.		

Social Impact Table 55 (Map 55C) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

MAP 55: PROJECT INFORMATION			
No pump stations, construction camps or block valve stations in the area.			
MAP 55: MAP HIGHLIGHTS			
• Little agricultural land. • Most of the route follows the summit of a ridge, bound east and west by small streams. • An energy transmission line bisects the pipeline. • Unclassified roads link local settlements.			
MAP 55: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** four settlements on this map will be directly impacted by the pipeline project. Three settlements (Cigcik, Yukari Bozkuyu, Asagi Bozkuyu) have land intersected by the proposed pipeline (L) and one settlement (Kaniagali mah) is within 500m of the pipeline route (D). No settlements are within 5km of a pump station (P), or within 2km of a block valve station. Settlements impacted by traffic have not yet been identified. No settlements are located down/upstream of a river. • ***Surveyed:*** two settlements (Cigcik, Asagi Bozkuyu) were surveyed in the field (S) and two settlements (Yukari Bozkuyu, Asagi Bozkuyu) were surveyed by telephone (T). • ***Not surveyed:*** Kaniagali Mah (350m from the pipeline) and Koyyeri (1.6km from the pipeline).			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Cigcik (L) (S)			
• ***Demographics:*** 900 inhabitants with approximately 180 households. This varies because some households live in the district centre and use their home and because 10% of inhabitants are seasonal labourers migrating from the settlement for agricultural or construction work. • ***Safety:*** the nearest household is 1,000m from the pipeline and the centre of the settlement is 1,500m. Cereal stubble is burnt (which is illegal in Turkey). • ***Health:*** insufficient sewage disposal is blamed for causing diseases. • ***Disputes:*** none • ***Project attitude:*** inhabitants would generally welcome a construction camp but are uninterested in the pipeline maybe because most of the forestland marked for the pipeline belongs to the state. Women were	***Sensitive crops (cotton)*** Dust may affect yields of crops essential for subsistence or commercial livelihoods ***Irrigation*** Potential loss of flow from	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. Contractor will **consult with authorities** to determine	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. If irrigation water is disrupted longer than time considered

Social Impact Table 55 (Map 55C) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

generally more interested. 64% of inhabitants have no concerns, 18% have a range of concerns including protection of forestland, burning of stubble, damage to roads by heavy machinery and pipeline security. 55% of inhabitants feel that they will benefit from direct employment, 18% are not sure what benefits there might be and 18% raised a range of 'other' benefits. • ***Land ownership & use:*** 70% of land is privately owned by local residents and 10% is communal. The forest near the settlement is primarily state owned (80%). Grazing (of cattle, sheep, poultry and goats) is carried out all year round. Land was expropriated in 1986, for the erection of a high voltage line. Grain, timber, fruit trees and cotton are grown. There are no fisheries or bee keeping. Permanent irrigation channels are present. • ***Settlement livelihood:*** agriculture, forestry, construction, transport, and trade. 10% of local residents are seasonal labourers migrating out of the settlement for work. • ***Availability & Skills:*** no previous experience. Six out of 24 construction skills including heavy machinery operators, heavy vehicle operator, welders and electricians having worked in the iron and steel factories in Adana and Iskenderun. 91% of respondents would accept a temporary job. • ***Settlement accessibility:*** the settlement is accessible all year round. It is 9km from Kadirli district centre. • ***Information provision:*** 90% of local residents are literate. Local information is obtained through families, whereas the Muhtar is the main source of national information. • ***Services:*** transport, market and restaurant facilities. There is a school with two teachers and 25 students. Higher grade students are transported to Kadirli. There are no health facilities, instead local residents travel to Yukaribozkuyu settlement. Doctors and nurses of the health group directorate of Kadirli neighbourhood make door-to-door health visits once every five months. • ***Infrastructure:*** there is piped water with regular supply. No alternative source is used. Electricity infrastructure is available. No sewerage systems or waste systems. Waste disposed of primarily	planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation. ***Accessibility to recruitment*** Decreased access to recruitment process ***Skills*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities,	maximum acceptable time for disruption. Winter road closures, seasonal migration and poor transport will **be taken into account** in the recruitment strategy **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within Project constraints. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Communication with settlement** must take into account settlement characteristics to ensure	acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be **compensated**. **No residual impact expected** **Potential positive benefits to local settlements.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will

Social Impact Table 55 (Map 55C) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

sewerage systems or waste systems. Waste disposed of primarily through recycling. Some households use solar energy. • ***Settlement problems:*** unemployment, low income, poor sewage system spreading diseases and repercussions from the current economic crisis in Turkey. Water for irrigation is a major need.	potential disruption to utilities, etc.	equal access to information for all residents. This should include using appropriate channels of communication and media.	keep this to a minimum.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Asagi Bozkuyu (L) (S) (T)			
• ***Demographics:*** 700 inhabitants with 140 households. Population has increased over the past five years. There is no seasonal migration. • ***Safety:*** the centre of the settlement is 1.25km from the pipeline, although the nearest household is 700m. • ***Project attitude:*** according to the Muhtar, local residents would welcome a construction camp. Local residents are generally aware of the pipeline and there was high female participation in meetings. 36% of households have no concerns, 36% think that there will be health and safety risks and 27% mentioned a range of 'other concerns'. In terms of benefits, 64% of households have expectations of direct employment, and 18% feel that there will be no benefits. • ***Main landowners:*** 35% of land is owned by local residents and 50% is communal. There is no seasonal grazing. The majority of landowners have title deeds. Grain, wine, grapes, and cotton are grown. In some cases multi-cropping takes place. Households have on average 1-2 cattle per household and a small number of sheep. There is no cattle breeding for commercial purposes. Temporary irrigation is used. • ***Settlement livelihood:*** agriculture, manufacturing, transport, trade, bee keeping and tailoring. 30% of respondents are farmers and 35% family labourers, although 30% have been unemployed for more than one year. Bee keeping is carried out by two households and is one of a number of sources of income. Local residents have had no previous pipeline experience, but 100% of households would accept	***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 55 (Map 55C) (KPs 1016.8 – 1032.9): West of Karatepe Aslantas National Park, Osmaniye Province

a temporary job. • ***Accessibility:*** the settlement is accessible throughout the year and is 14km from Kadirli district centre. • ***Information provision:*** according to the Muhtar, Turkish is spoken by all local residents. 90% of inhabitants are literate, although female literacy rates are low. TV, family, friends, and the Muhtar are the best local information sources and TV, radio, the Press, and the Muhtar for local information. • ***Services:*** there is a primary school. 50 students are transported to Kadirli for secondary schooling. There is a travelling health team and local residents also go to Yukaribozkuyu and Kadirli. • ***Infrastructure:*** piped, regular supply. Water is also transported to settlement via tankers. Pipeline intersects with drinking water mains. Electricity present, although 30-40 households use solar energy. There are no sewerage systems. Waste is burnt. • ***Settlement problems:*** unemployment, poor sewerage (potentially resulting in diseases), poor roads, inadequate access to water and insufficient irrigation.	***Sensitive crops (cotton/grapes)*** Dust may affect yields of crops essential for subsistence or commercial livelihoods ***Land*** Potential complications in expropriation process. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation. ***Accessibility of information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities etc. ***Construction hazards: animals***	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **See Overview of Land Acquisition Process in Appendix C9.** **Contractor will consult with authorities** to determine maximum acceptable time for disruption. **Communication** with settlement must take into account settlement characteristics to ensure equal access to information for all residents. This should include emphasising oral communication where literacy is low. **Livestock crossings** will be established at locations	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **See Overview of Land Acquisition Process in Appendix C9.** If irrigation water is disrupted longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be **compensated**. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **Potential for accidents involving livestock.**

	Trench poses safety hazard for livestock.	agreed with the community. Stock proof fencing will be erected in areas of danger for livestock.	Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure.

Environmental Impact Table 56 (Maps 56A and 56B) (KPs 1032.9 – 1048.7): Cukurova Plain, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Thermic Sandy Orthic Quartzipsamments.	Main potential impacts include: • sediment yield (at channel crossings); • soil productivity (disruption of agricultural calendar, physical disruption of soil profile); • soil contamination; • channel alteration (channel crossings); • waterlogging.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation – see typical drawings. Co-ordinate construction with farmers. Avoid construction on freshly irrigated soils: allow them to drain. Use equipment mats as required.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.
Landscape and Visual			
Landscapes in the northern part are expansive and mostly featureless - endless fields of cereals with occasional scattered trees or small copses interrupted sporadically by large or small irrigation canals. One notable exception is the castle sited on the top of Hamidiye Mountain, an isolated rocky outcrop just north of the settlement of Gokcedami, and visible from miles around. Just to the west of here, the route crosses the Ceyhan River, a wide, partly-braided river flowing in a wide floodplain of shingle islands and marshland. South of the river, smaller fields are more common and these are sown with row crops, mainly vegetables and melons, irrigated through a network of small, raised concrete irrigation aqueducts. Landscape values are low throughout.	Short-term construction modifications of landscape.	Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** Agricultural landscape is considered resilient to change. Therefore, only minor impacts are expected.
Surface Waters			
The pipeline route crosses Ceyhan River in this section. River channel is meandering, with a trapezoidal cross-section and mid-channel bars. Width	Direct disturbance to bank and bed morphology through	Apply standard mitigation measures in Section 6.4 and the	**MINOR IMPACT** Disturbance will be short-term

Environmental Impact Table 56 (Maps 56A and 56B) (KPs 1032.9 – 1048.7): Cukurova Plain, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
of river crossing is 130m, with a bank-full width of c.400m and a floodplain of >1,300m wide. Bed consists of sand and gravel and the flow is regulated, of a uniform and tranquil type. Low-flow channel may periodically migrate within the bank-full width of the flood-flow channel, although its movements at the crossing point will be constrained by width and bed controls, (ie boulders installed beneath the road bridge situated c. 250m upstream of crossing). Channel controls at the bridge may be expected to moderate channel expansion and flooding at the crossing point. Aslantas Reservoir may have limited capacity to moderate extreme flows at the pipeline crossing. Bank-side vegetation is comprised of shrubs and riparian vegetation is fragmented. Water quality samples taken 190m upstream of the crossing point indicate that this is a Class IV river. Ceyhan River flows into the Mediterranean Sea and is upstream of a number of irrigation districts and communities.	physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in already poor water quality. Potential for medium-term sedimentation and turbidity. Potential impacts on downstream ecology and water abstraction for human use.	RP, Appendix C2, for the protection of surface waters, Including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities, such as Orhaniye and Selimiye settlements, and provide where necessary if sedimentation and turbidity persist for more than 3 days at the community.	and limited to the immediate working area. Sedimentation of Ceyhan River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Groundwater			
The majority of the route continues to pass over the unconfined aquifer in the Cukurova (Adana-Ceyhan) Plain, with the remaining 2.5km passing over an area of confined aquifer (see Environmental Impact Table 55). The confined aquifer zone exists within the clay layer reaching a depth of 150m. Groundwater in this zone is of high enough quality for drinking purposes.	Potential for moderate and localised impacts to groundwater quality in the unconfined and confined aquifers from construction activities.	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including: • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	**MINOR IMPACTS** The confined aquifer zone is potentially a major drinking water resource, although its Class is not known at this stage. However, where mitigation measures described are applied, impacts are predicted to be minor at most and localised.
Ecology			
Important Ecological Factors			

Environmental Impact Table 56 (Maps 56A and 56B) (KPs 1032.9 – 1048.7): Cukurova Plain, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
The banks of Ceyhan River are an important ornithological area (KP 1037.0 to KP 1037.3). 1 Pied Kingfisher and 1 Common Kingfisher (both nationally-threatened) were recorded at the crossing. In addition, a very large colony of sand martins is present just downstream from the river crossing point. At KP 1048.1 1 Corncrake (globally-threatened, and most probably a migrant) and 1 Graceful Prinia (nationally-threatened) were recorded. The protection status for this species is given in Table 5.21, Section 5. Two fish species breeding in the Ceyhan river are on IUCN 2000 Red List – common carp, (*Cyprinus carpio*), (listed as Data Deficient), breeding between April and June, and loach sp. (*Orthrias tschaiyssuensis*), (listed as Vulnerable), breeding between May and July. Both the common carp and the sharptooth catfish, (*Clarias lazera*), which also breeds in this river between May and June, are of high commercial value. Additional seasonal sensitivities for fish species of medium commercial value are given in the EMMP (see Appendix C1).	Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods. The sand martin colony likely to be occupied from March to September. The corncrake was observed as a migrant and unlikely to be breeding in this area. Temporary disturbance to protected and commercially important fish species and aquatic plants providing breeding sites for fish during construction across the Ceyhan River.	Preconstruction survey to establish location of sand martin colony in relation to Ceyhan River crossing; if within 100m of the centre line of works, construction will be undertaken between October and March. The Sand Martin colony and areas of reeds and dense vegetation will be placed out of bounds for construction workers. In addition, the clearance of riverside vegetation in advance of the construction of watercourse crossing to be undertaken outside the April – July period for all other bird species breeding on the river banks. Shrubs and dense vegetation along the RoW will be cleared outside the breeding season for the Graceful Prinia (April to July). Construction activities at river crossings will not be permitted during the breeding season of fish species that are of high commercial value or that are designated has having conservation importance. For construction activity to be permitted during the breeding season of fish species with	**MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. This is critical for the sand martin where surveys identify the colony within 100m of the pipeline centreline. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April for all other bird species (except for the sand martin), and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACTS** at most for all fish species if construction takes place during August to February inclusive. At other times of year (varying by species), impacts will generally be **MINOR** on the basis of the rigid application of water crossing mitigation measures. Where construction is undertaken during the breeding season, impacts may be **MODERATE** for the IUCN listed species

Environmental Impact Table 56 (Maps 56A and 56B) (KPs 1032.9 – 1048.7): Cukurova Plain, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		medium commercial value, the Contractor will be required to submit specific mitigation measures to avoid impacting breeding fish to BOTAS for approval. Such measures will include, but not be limited to, the following: preconstruction survey results indicating that spawning grounds are avoided, the provision of fish passages, etc, in addition to the generic mitigation measures that are required at all river crossings.	common carp (April-June), loach species (May-July) and highly commercially valued sharptooth catfish (May to June).
Noise			
Gunluce settlement is located c. 203m from the centreline of the pipeline, and around 250m from a highway crossing.	Short-term noise impacts are expected to occur at Gunluce during soil stripping activities. Noise impacts will also occur during piling works associated with the nearby highway crossing.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised.	**MINOR IMPACT** Noise impacts are predicted to occur during piling activities associated with the highway crossing and soil stripping.

Environmental Impact Table 56 (Maps 56A and 56B) (KPs 1032.9 – 1048.7): Cukurova Plain, Osmaniye Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	

Social Impact Table 56 (Map 56C) (KPs 1032.9 – 1048.7): Cukurova Plain, Osmaniye Province

MAP 56: PROJECT INFORMATION
No pump stations, construction camps or block valve stations in the area.
MAP 56: MAP HIGHLIGHTS
• Key land use: irrigated agriculture. • Pipeline crosses two rivers (Ceyan and Altigoz). • Numerous irrigation channels and service roads cross the pipeline route. • An energy transmission line bisects the pipeline. • Unclassified roads link local settlements.
MAP 56: IMPACTED & SURVEYED SETTLEMENTS
• ***Impacted:*** 13 settlements will be directly impacted by the pipeline project (Orhaniye, Sakarcalik, Burnhali, Kaysu, Yenigun, Topraktepe, Kirmacili, Sadiye Karamezar, Haliciye, Sevkitiye, Yukari Ciyanli, Cigdemli, Hemite and Islamaglu). All of these settlements will have land intersected by the proposed pipeline (L). No settlements are within 5km of a pump station or construction camp, or within 2km of a block valve station (B). Two settlements (Sakarcalik, Sadiye Karamezar) are within 500m of the pipeline route (D). Settlements impacted by traffic have not yet been identified. One settlement (Catakli) is located upstream of the Altigoz river, crossed by the pipeline 1.6km south. • ***Surveyed:*** two settlements (Sakarcalik and Kayasu) were surveyed in the field (S) and nine settlements were interviewed by telephone (T). • ***Not surveyed:*** Gokcedam (200m from the pipeline), Gunluce (150m from the pipeline), Selmiye (1500m from the pipeline), Catakli (1.65km from the pipeline), Hamidiye (1.2km from the pipeline), Altigobekirli (2km from the pipeline), and Islamaglu (700m from the pipeline). • ***Not on the map:*** nine settlements (Kayasu, Yenigun, Sadiye Karamezar, Haliciye, Sevkitiye, Yukari Ciyanli, Cigdemli, Toprakepe, Hemite) with land intersected by the pipeline (L); and four other settlements; Islamaglu (700m from the pipeline); Altigobekirl (1771m from the pipeline); Hamidiye (893m from the pipeline) and Yukarici Yansu. • ***Disclosure Meeting Locations:*** Gunluce, Yenigun, Topraktepe

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Orhaniye (L) (T)			
• ***Demographics:*** 226 inhabitants. There is no seasonal migration. • ***Safety:*** 1.6km to the centre of the settlement. Possible earthquake area. • ***Project attitude:*** local residents are generally aware of the pipeline and according to the Muhtar, would welcome a construction camp. The Muhtar had no major concerns regarding the pipeline.	***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contaminations of flow from spills or increase in sedimentation.	Contractor **will consult** with authorities to determine maximum acceptable time for disruption.	If irrigation water is disrupted longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will

Social Impact Table 56 (Map 56C) (KPs 1032.9 – 1048.7): Cukurova Plain, Osmaniye Province

• ***Landownership and use:*** 70% of land is owned by local residents. There is no seasonal grazing or fishing. Seasonal irrigation is used by local residents. • ***Settlement livelihood:*** 90% of respondents are family labourer, and only 1% are in regular paid jobs. Bee keeping is carried out by four households and is a main source of income. • ***Availability & skills:*** local residents have no previous pipeline experience. • ***Distance from settlement to district centre:*** the settlement is 23.15 km from Osmaniye district centre. The settlement is accessible throughout the year. • ***Information provision:*** All local residents are literate. The main local sources of information are TV, families, friends the Muhtar and national sources include TV, radio, newspapers and Muhtar. • ***Environmental & cultural sites:*** the Muhtar stated that there is a castle. • ***Infrastructure:*** there is piped water but the supply is not regular. An artesian well is used. • ***Settlement problems:*** possible earthquake area.		***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided.	be **compensated.** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Sakarcalik (L) (D) (S)			
• ***Demographics:*** 1,000 inhabitants with 150 households. Increased birth rates have caused a rise in population over the past five years. There is no seasonal migration. • ***Safety:*** the centre of the settlement is 1km from the pipeline and the nearest household is 125m. • ***Health:*** poor sewerage and unhealthy drinking water contributing to ill health. Malaria is a problem in the summer. • ***Project attitude:*** according to the Muhtar, inhabitants would welcome the construction camp and there is no major hostility. 27% of households have no major concerns, 18% have a range of 'other' concerns (eg the impacts of dust on crops during harvest, impacts on	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.

Social Impact Table 56 (Map 56C) (KPs 1032.9 – 1048.7): Cukurova Plain, Osmaniye Province

water ducts/ channels) and 36% of households are concerned with health and safety. 46% of inhabitants have expectations of direct employment, and 18% have expectations of indirect employment. • ***Settlement livelihood:*** agriculture, construction, transport, and trade are the main sources of livelihood. 87% of respondents are family labourers, and 5% have regular paid jobs. • ***Main landowners:*** 75% of land is owned privately by inhabitants, 20% is communal, and 5% state owned. Grain, vegetables, herb, fruit trees, and cotton are the main crops. Cattle, sheep, poultry and goats are the main livestock kept in the settlement. Irrigation is used, and irrigation channels are in the same place each year. • ***Availability & skills:*** no previous experience. Seven out of 24 skills construction skills are available including heavy vehicle operator, mechanic, welders, lathe operators, repairmen, security personnel, and skilled construction workers. 55% of inhabitants would potentially accept a temporary job. Sand and stones (from the river) were cited as a potential construction resource by the Muhtar. • ***Accessibility:*** the settlement is accessible throughout the year. It is 19km from Merkez district centre. • ***Information provision:*** 80% of inhabitants are literate. Family, friends and the Muhtar are the main sources of local information. • ***Services:*** telephone services and transport services are available. There is a market. There is a primary school although students also travel to Gokcedag settlement. There is a travelling health team that visits the settlement, otherwise local residents travel 5km to Kirmitli town for health facilities. • ***Infrastructure:*** there is piped water supply although it is irregular. Each house has its own well, but these are located too close to the toilets. Electricity systems are present, although there are frequent cuts. There is no sewerage system and either cesspits are used or sewerage is disposed of into the stream. Most waste is burnt. • ***Settlement problems:*** income, poor sewerage impacting upon health, unhealthy drinking water. Economic problems – in debt to Agricultural bank and Agricultural Credit Cooperatives.	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock ***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Sensitive crops (cotton)*** Dust may affect yields of	settlement is within 500m of construction work. Community liaison meetings held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location. **Effectiveness of dust suppression** methods to be	**Any additional damage will be compensated for.** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression

Environmental Impact Table 57 (Maps 57A and 57B) (KP 1048.7 – 1050): Cukurova Plain, Adana/Osmaniye Province Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Soils types from the previous section continue in this section of the route: • Thermic Sandy Orthic Quartzipsamments.	Main potential impacts: • sedimentation at channel crossings; • soil productivity (disruption of agricultural calendar, physical disruption of soil profile); • channel alteration (channel crossings); • waterlogging.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation – see typical drawings. Co-ordinate construction with farmers. Avoid construction on freshly irrigated soils: allow them to drain. Use equipment mats as required.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed**.**
Landscape and Visual			
Small fields are common and these are sown with row crops, mainly vegetables and melons, irrigated through a network of small, raised concrete irrigation aqueducts. Landscape sensitivities are low throughout.	Short-term construction modifications of landscape.	Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** Agricultural landscape is considered resilient to change. Therefore only minor impacts are expected.
Groundwater			
The route continues to pass over the Cukurova (Adana-Ceyhan) Plain (see Environmental Impact Tables 55 and 56). Approximately 1km of the unconfined aquifer and c. 1.8km of the confined aquifer are crossed. Groundwater in the confined aquifer is of high enough quality for drinking purposes.	Potential for moderate and localised impacts to groundwater quality in the unconfined aquifer from construction activities.	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including • No groundwater abstraction within 50m of springs or wells. Groundwater will not be	**MINOR IMPACT** The confined aquifer zone is potentially a major drinking water resource, although its Class is not known at this stage. However, where mitigation measures described are applied,

Environmental Impact Table 57 (Maps 57A and 57B) (KP 1048.7 – 1050): Cukurova Plain, Adana/Osmaniye Province Border

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	impacts are predicted to be minor at most and localised.

Social Impact Table 57 (Map 57C) (KPs 1048.7 – 1050): Cukurova Plain, Adana/Osmaniye Province Border

MAP 57: PROJECT INFORMATION
There are no pump stations, construction camps or block valve stations in the area.
MAP 57: HIGHLIGHTS
• Land use is dominated by irrigated agriculture.
MAP 57: SURVEYED AND IMPACTED SETTLEMENTS
• No settlements are located on this map.

Environmental Impact Table 58 (Maps 58A and 58B) (KPs 1050 – 1064.2): Cukurova Plain, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
• Thermic Sandy Orthic Quartzipsamments. • Thermic Orthic Calcixerolls, which are often truncated on steep slopes.	Main potential impacts include: • sediment yield (channel crossings); • soil erosion; • soil productivity (disruption of agricultural calendar, physical disruption of soil profile); • channel alteration (channel crossings); • waterlogging.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration. • Channel stabilisation – see typical drawings. Co-ordinate construction with farmers. Avoid construction on freshly irrigated soils: allow them to drain. Use equipment mats as required.	**MINOR IMPACT** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor. Furthermore, soil productivity losses are predicted to last less than 3 months after construction is completed.
Landscape and Visual			
Predominantly landscapes of intensive, irrigated cereals, but smaller fields are common and these are sown with row crops, mainly vegetables and melons, irrigated through a network of small, raised concrete irrigation aqueducts. Further south, the route crosses the main Adana-Osmaniye motorway, the Karacay River, and another major highway in quick succession; the river a wide, deep, slow-flowing river with dense emergent vegetation along its banks in marked contrast to the fast-flowing mountain rivers seen earlier along the route. Landscape sensitivities are low throughout.	Short-term construction modifications of landscape.	Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** Agricultural landscape is considered resilient to change. Therefore, only minor impacts are expected to occur.
Surface Waters			
The pipeline route crosses Karacay River, which is canalised with a trapezoidal cross-section with mid-channel bars. Width of crossing is 23m	Direct disturbance to bank and bed morphology through	Apply standard mitigation measures in Section 6.4 and the	**MINOR IMPACT** Disturbance will be short-term

Environmental Impact Table 58 (Maps 58A and 58B) (KPs 1050 – 1064.2): Cukurova Plain, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
and the bank-full width is c.8m, with no floodplain. Levees have been constructed. Bed consists of sand and the flow is perennial, of a uniform and tranquil type. Bank-side vegetation is comprised of shrubs with no riparian vegetation. The D400 motorway crosses the river c. 0.4km upstream of the pipeline crossing point. Water quality samples taken 400m downstream of the crossing point indicate that this is a Class III river. Gunyazi Settlement is 0.5km downstream of the crossing point.	physical works, and indirectly, due to run-off containing suspended solids from working areas resulting in a reduction in water quality. Water quality indicates that Karacay River is polluted and further degradation in quality will be avoided. Potential for short to medium-term sedimentation and turbidity. Potential impacts on downstream ecology and water abstraction for human use.	RP, Appendix C2, for the protection of surface waters, including: • use of appropriate sediment filters or trapping devices; • techniques to divert/separate flow from open trench. Assess need for alternative water supply for downstream communities, eg Gunyazi Settlement, and provide where necessary if sedimentation and turbidity persist for more than 3 days at the community.	and limited to the immediate working area. Sedimentation of Karacay River will only be visible for less than 3 weeks after construction, with no obscuration of the river bed.
Groundwater			
The majority of the route continues to pass over the Cukurova (Adana-Ceyhan) Plain (unconfined aquifer). Groundwater samples were taken from wells located c. 2.4km east of the route near KP 105.3 (Well Site No.16) and c. 2km west of the route near KP 105.9 (Well Site No.17). Results indicate that groundwater quality is Class II. BVS-052 will be located at KP 1061.2 on the unconfined aquifer. Approximately 350m^2 of permanent landtake required. A new access road will be constructed to the site of c. 50m in length.	Potential for moderate and localised impacts to groundwater quality from construction of both the Pipeline and BVS-052.	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including: • No groundwater abstraction within 50m of springs or wells. Groundwater will not be abstracted for use as hydrotest water. • No facilities (construction camps, pipe yards, fuel stores etc) will be located within 50m of springs or wells.	**MINOR IMPACT** Where mitigation measures described are applied, impacts are predicted to be minor at most and localised.
Ecology			
Important Ecological Factors			**MODERATE IMPACTS**

Environmental Impact Table 58 (Maps 58A and 58B) (KPs 1050 – 1064.2): Cukurova Plain, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
ESA 49 is identified between KP 1060.6 and KP 1061.1 for the globally-threatened plant species (*Ophrys transhyrcana sp. amanensis*).The IUCN status for these species are given in Table 5.20, Section 5. A large slow-flowing, eutrophic, irrigation canal with well-developed marginal vegetation is located between KPs 1055.4 – 1056 and parallel to the route. The canal supports an interesting riparian bird community including three nationally-threatened species: 2 White-breasted Kingfisher, 2 Common Kingfisher, & 1 Graceful Prinia. Another White-breasted Kingfisher was present near the Karacay River but outside of the construction corridor. The protection status for these species are given in Table 5.21, Section 5. At KP 1054.9, near the Karacay River crossing, the European Pond Turtle (globally-threatened) was recorded. The protection status for this species is given in Table 5.21, Section 5. The common carp, (*Cyprinus carpio*) breeds in the Karacay river between April and June and is categorised in IUCN 2000 Red List as Data Deficient. This species is also of high commercial value, along with the sharptooth catfish (Clarias lazera), which breeds in this river between May and June. Additional seasonal sensitivities for fish species of medium commercial value are given in the EMMP (see Appendix C1).	Habitat destruction of areas peripheral to cultivated lands may result in the loss of individuals from populations of globally-threatened plants. Potential for direct disturbance to nationally-threatened birds during nesting, feeding or indirectly, through habitat loss if construction is undertaken during the breeding season (ie between April and July inclusive). July can remain sensitive for late and second broods. Temporary localised disturbance to globally-threatened reptile between May and September inclusive. The European Pond Turtle typically mates in May, with eggs (up to 10 per clutch) laid amongst the roots of waterside vegetation in June. Incubation period is dependent upon variable by temperature, but is generally in the order of 70 days. Hatchlings emerge August – September. Temporary disturbance to	Threatened plant species will be identified and located during pre-construction surveys, particularly within ESA 49. The feasibility of translocating species will be assessed prior to construction. Where only a few individuals occur, these will be translocated outside of the RoW if the same habitat exists and if this is possible. Otherwise one or a combination of the following techniques will be used, supervised throughout by a botanical specialist (appointed as described in the EMMP, see Appendix C1): • remove and keep top soil and sub-soil separate, protect top soil, and replace correctly; • take turfs containing the threatened plants and nurture until replacement during reinstatement of the RoW. Care will be taken in using fertiliser during re-instatement since it has an adverse effect on non-grass species. It will be used sparingly or not at all in ESA 49. Preconstruction survey to establish location of breeding birds along the irrigation canal; if within 100m of the centre line of works,	Short-term disturbance to internationally important flora. The Construction Contractor will ensure that construction planning achieves a 21-day period from the time when the ESA is entered to the completion of reinstatement (see the RP, Appendix C2). **MINOR IMPACTS** at most for breeding birds, where pipeline construction is scheduled to avoid seasonal sensitivities. Where the construction schedule dictates work during the breeding season, impacts will be **MINOR**, where the RoW is cleared prior to April, and **MODERATE**, where construction occurs during the breeding season without prior clearance of the RoW. **MINOR IMPACTS** only to a globally-threatened reptile, if the construction period avoids the seasonal sensitivity. **MINOR IMPACTS** at most for all fish species if construction takes place during July to February inclusive. At other times of year (varying by

Environmental Impact Table 58 (Maps 58A and 58B) (KPs 1050 – 1064.2): Cukurova Plain, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
	protected and commercially important fish species and aquatic plants providing breeding sites for fish during construction across the Karacay River.	construction will be undertaken between August and March. In advance of construction works associated with the Karacay River crossing, riverside vegetation will be cleared between beginning of October and end of April, ie outside of the breeding season for the European Pond Turtle. Construction activities at river crossings will not be permitted during the breeding season of fish species that are of high commercial value or that are designated has having conservation importance. For construction activity to be permitted during the breeding season of fish species with medium commercial value, the Contractor will be required to submit specific mitigation measures to avoid impacting breeding fish to BOTAS for approval. Such measures will include, but not be limited to, the following: preconstruction survey results indicating that spawning grounds are avoided, the provision of fish passages, etc, in addition to the generic mitigation measures that are required at all river	species), impacts will generally be **MINOR** on the basis of the rigid application of water crossing mitigation measures. Where construction is undertaken during the breeding season, impacts may be **MODERATE** for the IUCN listed species common carp (April-June) and highly commercially valued sharptooth catfish (May to June).

Environmental Impact Table 58 (Maps 58A and 58B) (KPs 1050 – 1064.2): Cukurova Plain, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		crossings.	
Noise			
Islamoglu settlement is located c. 428m from both the pipeline centreline and a highway crossing. Gunyazi is located c. 203m from the Pipeline and c. 450m from a highway crossing.	Noise impacts associated with piling activities required during highway crossings will occur at Islamoglu and at Gunyazi. Short-term noise impacts will also occur at Gunyazi during soil stripping.	The following mitigation measures will be applied: • use of silenced/low noise construction plant and machinery; • provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels; • all hours of work will be agreed with the relevant authorities prior to the commencement of works; • plant and machinery will be sited away from inhabited buildings; • existing screening, including that arising from the stockpiling of materials and spoil will be utilised. The Construction Contractor will develop site-specific noise mitigation measures, such as the use of mobile noise barriers to screen dwellings for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP (see Appendix C4).	**MINOR IMPACT** Noise impacts are expected to occur at Gunyazi during soil stripping activities. During soil stripping it may not be possible to utilise spoil to screen dwellings from the works, and hence, noise impacts are likely to occur. However, this will be short-term in nature, lasting only for a few days. **MINOR IMPACT** Assuming that the mitigation measures described are implemented during construction, noise impacts are predicted to be minor and occur only during the short-term at Islamoglu and Gunyazi during piling activities.
Archaeology and Cultural Heritage			

Environmental Impact Table 58 (Maps 58A and 58B) (KPs 1050 – 1064.2): Cukurova Plain, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Kırteke Mound is a settlement mound located on the edge of the 100m Corridor. Part of this site has been registered by the MoC as a 1st Degree Site, with the remaining registered as a 3rd Degree Site. However, the full extent of this site is unknown.	Potential for direct impacts, such as ground disturbance, at these sites during pipeline construction. Indirect impacts may arise from construction activities that will affect the visual/historical setting of these sites.	The extent Kırteke Mound will be investigated during further field surveys prior to construction. This will determine whether the site extends into the construction corridor and whether there will be a need for detailed surface research and/or rescue excavations at this site. Further investigation will delineate this site and identify a safe route through. Specific mitigation to be developed following site investigations. The MoC classification for the site will be determined from investigations. Construction will be carried out under the supervision of an archaeologist authorised by BOTAŞ.	**MODERATE TO MINOR IMPACTS** Residual impacts cannot be determined precisely for this site at this stage since the extent is unknown. Archaeological investigations prior to construction will establish the full extent of the site. However as investigations are expected to find a safe route through these sites, the ultimate scale of impact is likely to be minor and short-term in duration.

Adana Socio-Economic Overview

Demographics:
Adana is the largest surveyed province in terms of population. It has 1.7 million inhabitants, 8% of whom live within the pipeline corridor. It is also the most densely populated province (112 inhabitants per km^2). It has experienced significant in-migration and seasonal migration of agricultural workers particularly from south-east Anatolia. 70% of the province population live in urban areas, the highest levels of urbanisation encountered along the pipeline. The average household size is lower than the survey average and indicative of more urbanised, nuclear households. All individuals surveyed speak Turkish and the majority of inhabitants are Sunni Muslims, although Alevi and Shiite Muslims are present.

Land:
There is a high degree of land inequality and polarisation compared with other provinces, together with high crop production and high diversification of output (including vegetables and fruit). According to the SIS, 45% of land in Adana is irrigated (exceeding the national average of 21%). Villagers (owner cultivators) and the State, are the primary and secondary landowners respectively. The average landholding is 46ha.

Livelihoods:
Adana is one of the most developed and industrialized provinces in Turkey (particularly around Ceyhan district). However, industrial activities are non-existent within the pipeline corridor (with the exception of the existing BOTAŞ Marine Terminal and the Toros Gübre Fertiliser facilities in Kurtpinari). Adana is ranked top of the surveyed provinces in terms of wealth (assets and income). However, living standards have decreased over the past five years due to the increasing cost of agricultural production and the Turkish economic crisis. In the seven settlements surveyed, abundance of fertile land and irrigation possibilities makes agriculture (accompanied by small-scale livestock breeding) the most widespread way of maintaining a livelihood. A significant number of people owe considerable amounts of money to agricultural loans co-operations.

Infrastructure & Services:
Formal sewerage systems and solid waste disposal systems are very rare. A high proportion of settlements have a mosque, primary school and health centre. Literacy rates are relatively high and 74% of respondents have primary or secondary education. Electricity, water and telephone networks are available although supply, particularly of the former, is irregular.

Key Problems:
The main problems for local residents are the lack of services, particularly the inadequacy of water networks and the increasing difficulties experienced in meeting livelihood needs.

Project Attitude:
Previous experience of industrial developments and underemployment of local people, means that the surveyed respondents have high expectations for permanent employment and request timely payment of compensation for land expropriation for the BTC Project.

Source: Household and Settlement Survey (2001) (Note: Only pipeline baseline data used, not marine terminal data)

Social Impact Table 58 (Map 58C) (KPs 1050.0 – 1064.2): Cukurova Plain, Adana Province

MAP 58: PROJECT INFORMATION			
There are no pump stations or construction camps in the area. There is one block valve station.			
MAP 58: MAP HIGHLIGHTS			
• Major land use is irrigated agriculture, with some non-agricultural land and rain-fed agriculture. • The pipeline crosses the Mercin River, two motorways, a railway and numerous unclassified roads. • The Islamoglu mound lies within the corridor to the east of the route. • An energy transmission line bisects the pipeline.			
MAP 58: IMPACTED & SURVEYED SETTLEMENTS			
• ***Impacted:*** four settlements on this map will be directly impacted by the pipeline project. Three of these (Imran, Hamdilli, Selimiye) have land intersected by the proposed pipeline (L); and three settlements (Gunyazi, Imran and Sogukpinar) are within 500m of the pipeline route (D). No settlements are within 5km of a pump station or construction camp. One settlement (Erenler) is within 2km of the block valve station (B). Settlements impacted by traffic have not yet been identified. One settlement (Gunyazi) is downstream of the pipeline crossing on the Mercin River. • ***Surveyed:*** four settlements (Gunyazi, Erenler, Imran, Hamdilli) were surveyed in the field (S) and three settlements (Dagistan, Selimiye and Hamdilli) were surveyed by telephone (T). • ***Not surveyed:*** Islamoglu Mah (500m from the pipeline); Kuzucak (1.8km from the pipeline); Sogukpinar (400m from the pipeline); and Degirmendere (2km from the pipeline).			
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Dagistan (T)			
• ***Demographics:*** 235 inhabitants with 90 households. 2% of inhabitants migrate seasonally. • ***Safety:*** the nearest household is 900m from the pipeline and the settlement centre is 1.2km away. • ***Project attitude:*** inhabitants would welcome a construction camp, there is no awareness of the pipeline project, and no major concerns or expected benefits seen. • ***Land ownership & use:*** 60% of land is owned by local residents. There is seasonal grazing and bee keeping, but no fishing or hunting. Seasonal irrigation is undertaken.	***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Irrigation***	**Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. Contractor will **consult** with	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **If irrigation water is**

Social Impact Table 58 (Map 58C) (KPs 1050.0 – 1064.2): Cukurova Plain, Adana Province

Seasonal irrigation is undertaken. • ***Settlement livelihood:*** agriculture, bee keeping, transport, trade and education are the main areas of employment. 100% of the local residents are farmers. • ***Availability & skills:*** previous experience, on the NGP. • ***Accessibility:*** the settlement is accessible throughout the year; it is 21km from the district centre. • ***Information provision:*** 90% of the local residents are literate. Local and national information is obtained through TV, radio and paper. • ***Infrastructure:*** piped water is provided although irregular, stored water is used as an alternative water source. • ***Settlement problems:*** no major problems.	Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation.	authorities to determine maximum acceptable time for disruption. .	**disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Gunyazi (D) (R) (S)			
• ***Demographics:*** 613 inhabitants with 100 households and no recent change in population. Villagers retired from their jobs in other provinces have returned. • ***Safety:*** the settlement centre is 700m from the pipeline, and the nearest house is 300m from the pipeline. • ***Health:*** there are insufficient health facilities, therefore facilities in neighbouring Handilli town are used. • ***Disputes:*** 'other' disputes, ie individual and family problems. • ***Project attitude:*** inhabitants would welcome a construction camp. The local people are aware of the pipeline, but they are concerned about leakages and sabotage. They will be positive as long as there are no damages, and there are no adverse impacts to the environment and agriculture. 73% of respondents have expectations of direct employment and 9% perceive no benefits. 55% of respondents had no major concerns, and the remaining respondents had a range of concerns eg regarding health and safety risks. • ***Land ownership & use:*** 28% of land is owned by local residents, 19% is communal. There are problems related to inheritance and	***Construction hazards: human*** Working areas pose safety hazard to residents, particularly small children. Land beyond that compensated for may be affected if mitigation measures are not fully	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Protective barrier fencing** will be erected where a settlement is within 500m of construction work. **Community liaison meetings** held during and immediately following construction will identify any	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. Any **additional damage will be compensated for.**

Social Impact Table 58 (Map 58C) (KPs 1050.0 – 1064.2): Cukurova Plain, Adana Province

land deeds. Key crops cultivated are grain, cotton, corn, and soya beans. Land allocated for cotton has decreased recently as diseases that affect corn plants have occurred in the present year and some cotton fields could not be harvested. Beekeeping is carried out, but there is no fishing or hunting. A grazing area of 2700 acres is used for cattle (700-750 in number), poultry and sheep (60-70 in number). There is all year grazing. Permanent irrigation channels are used. • ***Settlement livelihood:*** agriculture, animal husbandry, bee keeping and trade are the main settlement activities. Agriculture and animal breeding are unprofitable. 7% of inhabitants have been unemployed (for less than one year), 4% unemployed (for more than one year), 2% have regular paid jobs, 1% are seasonal labourers and 40% are family labourers. • ***Availability & skills:*** some people have previous experience. Five to six local residents have worked as welders in various pipeline projects in Russia and Saudi Arabia. Transmission lines and filter installation cities were constructed in the vicinity of the settlement. Eight out of 24 construction skills are available in the settlement including heavy vehicles drivers, heavy machinery operators, and administrative skills. 55% of inhabitants are available for temporary jobs. • ***Accessibility:*** the settlement is accessible throughout the year. The settlement is 15 km to the district centre. • ***Information provision:*** The literacy rate is 95%. Local sources of information are: the family, Muhtar and national sources are TV, and newspapers. • ***Environmental & cultural sites:*** none • ***Services:*** telephone services, coffee houses, a market, and transport services. There are no health facilities and local residents use the services in Hamdilli town, which is difficult in emergencies. • ***Infrastructure:*** there is piped, irregular supply of water, from Tartali settlement, which is affected by electricity cuts. There is no alternative water source. There is an electricity system in place although there are frequent power cuts. There are no sewerage	implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Bees*** Disturbance of any stationary hives located within 300m of the route. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	additional land that has been affected. **Livestock crossings** will be established at locations as agreed with the community. Consider erecting stock proof fencing. Stock proof fencing will be erected in areas of danger for livestock. **Beekeeping: stationary hives.** Inform owner of need to move hives to a position at least 300m from the route. If moved during the productive season, stationary hives must be temporarily moved at least 7km from their original position for 15-20 days prior to moving back close to their original location. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts expected.** If settlements believe that more than 10% of suitable bee foraging vegetation will be affected, a location specific bee assessment is to be carried out to assess the need for compensation. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 58 (Map 58C) (KPs 1050.0 – 1064.2): Cukurova Plain, Adana Province

systems, and sewage is discharged via the drainage ducts. Pumping machines are also sometimes used for this purpose. There is no waste system. • ***Settlement problems:*** insufficient health facilities. Inhabitants suggest that the political and economic problems of the country have also affected the settlement.		construction.	
	Land Potential complications in expropriation process.	**See Overview of the Land Acquisition Process in Appendix C9**	**See Overview of the Land Acquisition Process in Appendix C9.**
	Sensitive crops (cotton) Dust may affect yields of crops essential for subsistence or commercial livelihoods.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.
	Irrigation Loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation.	Contractor will **consult** with authorities to determine maximum acceptable time for disruption.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated
	Skills and Resources Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials.	**Information is highlighted to Contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints.	**Potential positive benefits** to local settlements.

Hamdilli town (L) (S)			
• ***Demographics:*** 1,650 inhabitants with 325 households, there has been a recent decrease in population, due to emigration to Adana and other metropolitan areas for employment and to pursue university education. 20 households have settled in Germany and Austria. There is no seasonal migration. • ***Safety:*** the settlement centre is 1.8km from the pipeline. • ***Health:*** unhealthy drinking water with potential for causing health problems. • ***Disputes:*** there are serious conflicts between local political parties. • ***Project attitude:*** the inhabitants want a construction site to be established near the town. Although there seems to be awareness of the project, the general attitude is one of indifference. The inhabitants have no concerns and will give their support provided no damage occurs. The key perceived benefit is direct employment (72%).	***Sensitive crops (cotton)*** Dust may affect yields of crops essential for subsistence or commercial livelihoods. ***Construction hazards: animals*** Trench poses safety hazard	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **Livestock crossings** will be established at locations agreed with the community.	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **Potential for accidents involving livestock.** Financial compensation will

Social Impact Table 58 (Map 58C) (KPs 1050.0 – 1064.2): Cukurova Plain, Adana Province

• ***Land ownership & use:*** local residents own 50% of land and 25% is used by the settlement. There are problems regarding inheritance and land deeds. Livestock is grazed all year round. Some land is irrigated and channels are kept in the same place between years. The key crops are grain, cotton, soya beans and peanuts. There is no fishing or bee keeping. • ***Settlement livelihood:*** agriculture and breeding animals for milk. Other livelihoods are trade, manufacturing, construction, tourism and education. 33% of inhabitants are family labourer, 5% are unemployed (for less than a year), 2% are unemployed (for more than a year), 3% have regular paid jobs and 1% are seasonal labourers. • ***Availability & skills:*** no previous experience although the Nato pipeline passes close by. 8 out of 24 construction skills, including heavy vehicles drivers, welders and heavy machinery operators. 64% of inhabitants are willing to take on temporary jobs. • ***Accessibility:*** the settlement is accessible through the year, although transport is a key settlement problem. The distance from settlement to district centre is 12km. • ***Information provision:*** The literacy rate is 99%. The local sources of information are TV, family, friends, Muhtar and the national sources of information are TV, radio, newspapers and the Muhtar. • ***Services:*** coffee houses, market, transport, post office, police, and sports facilities. There is a school, and local health facilities including a midwife, a health centre and a doctor. • ***Infrastructure:*** piped, regular supply of water. In addition, each house has a well and a pump. There is electricity although there are frequent cuts. Sewerage and waste systems are present. Waste is disposed of in the settlement dump. • ***Settlement problems:*** transport, unemployment, poor roads, insufficient infrastructure and sewerage systems and unhealthy drinking water.	for livestock. ***Land*** Potential complications in expropriation process. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Contamination of flow from spills or increase in sedimentation. ***Accessibility to information*** Sectors of the population may not have access to project related information on	Stock proof barriers will be erected in areas of danger for livestock. **See Overview of the Land Acquisition Process in Appendix C9.** ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information	be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of the Land Acquisition Process in Appendix C9.** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum.

Social Impact Table 58 (Map 58C) (KPs 1050.0 – 1064.2): Cukurova Plain, Adana Province

	employment opportunities, potential disruption to utilities, etc. ***Skills and Resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials.	for all residents. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints.	**Potential positive benefits** to local settlements.
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Erenler (S)			
• ***Demographics:*** 300 inhabitants with 55 households. There has been a recent decrease in population, due to emigration of young people for education. • ***Safety:*** the settlement centre is 934m from the pipeline. • ***Project attitude:*** a construction camp would be welcome. The general attitude towards the project is very positive. 64% of inhabitants had no concerns and direct employment was the key perceived benefit by 64% of the inhabitants. • ***Land ownership & use:*** 60% of land is owned by local residents and 25% is communal. There are problems with land deeds. There is no irrigation. Key crops are grain, vegetables, cotton, fruit trees. There is grazing throughout the year. • ***Settlement livelihood:*** agriculture is the main livelihood, there is no animal husbandry (except for 1 household). 40% of inhabitants are family labourers, 6% are unemployed (<year), and 3% are unemployed (>year). • ***Availability & skills:*** no previous experience. There are 8 out of 24 construction skills. 64% of inhabitants are willing to take on temporary	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards:***	**Road safety training** will be held in schools prior to construction commencing. **Community liaison meetings** held prior to and during construction will include safety briefings. **Community liaison meetings** held during and immediately following construction will identify any additional land that has been affected. **Livestock crossings** will be	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising. **Any additional damage will be compensated for.** **Potential for accidents**

Social Impact Table 58 (Map 58C) (KPs 1050.0 – 1064.2): Cukurova Plain, Adana Province

jobs. There is a coalmine in operation. • ***Accessibility:*** the settlement is accessible but transportation is difficult in winter. The distance from the settlement to the district centre is 9km. • ***Information provision:*** There is a 100% literacy rate. Local information sources are TV, family, friends, and the Muhtar, national sources of information are TV, radio, newspapers, and the Muhtar. • ***Environmental & cultural sites:*** civilian architecture, forest • ***Services:*** coffee houses, market, transport and sports facilities. There are no schools. Health facilities are traditional, the facilities of Hamdilli town (4km) and Ceyhan (10km) are used. • ***Infrastructure:*** piped, although irregular water supply. There is no alternative water source. Electricity systems are present. There are no sewerage or waste systems, and waste is disposed of in the settlement dump. • ***Settlement problems:*** unemployment is the main problem and inhabitants do not think unemployment can be prevented. Other problems are lack of education and insufficient health conditions, frequent electricity cuts affecting water availability.	***animals*** Trench poses safety hazard for livestock. ***Accessibility to information*** Sectors of the population may not have access to project related information on employment opportunities, potential disruption to utilities, etc. ***Skills and resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials. ***Land*** Potential complications in expropriation process.	established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger for livestock. **Communication with settlement** must take into account settlement characteristics to ensure equal access to information for all residents. Asking residents or workers to translate as necessary. **Information is highlighted to contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints. **See Overview of the Land Acquisition Process in Appendix C9.**	**involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **Any change can highlight and exacerbate existing divisions** in communities. Mitigation measures will keep this to a minimum. **Potential positive benefits** to local settlements. **See Overview of the Land Acquisition Process in Appendix C9.**

Social Impact Table 58 (Map 58C) (KPs 1050.0 – 1064.2): Cukurova Plain, Adana Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Selimiye (L) **(T)**			
• ***Demographics:*** 260 inhabitants. 15% of inhabitants migrate seasonally. • ***Safety:*** settlement centre is 1.75km from the pipeline • ***Project attitude:*** a construction camp would be welcome. There is general awareness about the pipeline project and there are no major concerns. • ***Land ownership & use:*** 50% of land is owned by local residents and 50% is communal. There is no seasonal grazing. There are no fisheries or bee keeping. There is no irrigation. • ***Settlement livelihood:*** agriculture, mining, construction, trade and education. 85% of inhabitants are farmers, 5% are unemployed (<year) and 10% have regular paid job. • ***Availability & skills:*** previous experience eg the Tefken project. • Accessibility: settlement is accessible except in January and February. The settlement is 16.5 km to the nearest district centre. • ***Information provision:*** Literacy rate is 100%. Local sources of information are TV, family, friends, Muhtar, and national sources are TV, radio, paper, and the Muhtar. • ***Environmental & cultural sites:*** mausoleum. • ***Infrastructure:*** there is no piped water available, the settlement uses the settlement fountain. • ***Settlement problems:*** inadequate access to water, low income, unemployment.	***Land*** Potential complications in expropriation process. ***Accessibility of recruitment*** Decreased access to recruitment process.	**See Overview of the Land Acquisition Process in Appendix C9.** ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy	**See Overview of the Land Acquisition Process in Appendix C9.** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. **No residual impact expected.**

Environmental Impact Table 59 (Maps 59A and 59B) (KP 1064.2 - 1076, end of pipeline route): North-East of Sagirlar Settlement to the End of the Pipeline Route, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
Soils			
Thermic Orthic Calcixerolls, which are often truncated on steep slopes.	Main potential impacts include: • soil erosion; • sediment; • soil productivity.	• Topsoil removal and storage; subsoil removal and storage; and reinstatement of soils. • Permanent erosion control devices. • Sediment interception and sediment settling ponds where required by the landowner/occupier. • Bio-restoration.	**MINOR IMPACTS** Soil erosion will be short-term and is predicted to occur at approximately the same rate as soil formation. There will be no change in erosion class, or the change will be limited to less than a 100m section of the corridor.
Landscape and Visual			
The final reach of the Pipeline rises over a series of low rounded hills running more or less parallel to the coast (130m asl), the tops and valleys of which are cultivated with cereals and whose steep sides remain covered with maquis. The route then descends into the existing BOTAŞ Marine Terminal.	Some loss of trees and bushes particularly from areas of maquis. Short-term construction modifications of landscape.	Apply 'Soils' reinstatement specifications above.	**MINOR IMPACT** Small loss of bushes in denser areas of maquis leaving narrow straight gaps. Otherwise the agricultural landscape is considered resilient to change.
Groundwater			
Approximately 1.5km of the Cukurova (Adana-Ceyhan) Plain (unconfined aquifer) lies within the 500m Corridor but is not crossed by the pipeline route. Groundwater samples were taken from this aquifer at two wells sites, c. 1.6km east of route (Well Site No. 18 - Akpinar Settlement) and c. 1.5km east of route (Well Site No. 19 - Kurtpinar Settlement). Results indicate that groundwater quality is Class II.	Potential for minor and localised impacts to groundwater quality where activities such as re-fuelling, vehicle washing or maintenance occur in, over or adjacent to a drain or watercourse, (ie Kalebogazi Creek).	Apply standard mitigation measures in Section 6.5 to avoid reducing groundwater quality and conflicting with other users, including: • Fuelling, washing or maintenance of plant or machinery will not occur in, over or adjacent to a drain or watercourse. • No groundwater abstraction within 50m of springs or wells.	**MINOR IMPACT** With the application of the specified mitigation measures described, only minor impacts are expected to occur, which will be short-term in nature.

Environmental Impact Table 59 (Maps 59A and 59B) (KP 1064.2 - 1076, end of pipeline route): North-East of Sagirlar Settlement to the End of the Pipeline Route, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
		Groundwater will not be abstracted for use as hydrotest water.	
Ecology			
Important Ecological Factors At KP 1072 (near a provincial highway crossing), the Mehely's Horseshoe Bat (a globally-threatened species) was recorded. The protection status for this species is given in Table 5.21, Section 5.	Minor temporary disturbances are expected to globally-threatened mammals during seasonal sensitivities (see EMMP, Appendix C1): • the Mehely's Horseshoe Bat gives birth in late spring and hibernates in hollow trees, ruins, tunnels, garrets or caves from September/October to spring (May).	Preconstruction surveys during the summer months for the Mehely's Horseshoe Bat will establish the presence and abundance of the species and seek to identify summer colonies and potential winter hibernation roosts. Hollow trees within the RoW of the Pipeline will be removed during the late summer months to prevent their use as winter roosting sites and to allow construction to continue during the autumn, winter and early spring periods. Caves, ruins or underground cavities, which have been identified as hibernation roosts (particularly those close to camps and works sites), will be secured, and placed out of bounds, to avoid their disturbance by workers.	**MINOR IMPACT** at most to a globally-threatened mammal during the construction period where the specified mitigation measures are applied for the seasonal sensitivities identified.
Archaeology and Cultural Heritage			
There are three archaeological sites lying within the 100m Corridor that may be potentially impacted during pipeline construction: • Gokdere (3rd Degree Site*) – ancient settlement. There are traces of buildings at this site, dating back to the Roman period. • Maltepe South – 'Classical Site'. There are traces of buildings at this site, dating back to the Roman period.	Potential for direct impacts, such as ground disturbance, at these sites during pipeline construction. Indirect impacts may arise	The re-routing of the Pipeline around the site at Gokdere will be further investigated during field surveys prior to construction. Further investigation will delineate this site and identify whether a re-	**MODERATE TO MINOR IMPACTS** Residual impacts cannot be determined precisely for Gokdere at this stage since the re-route will be subject to

Environmental Impact Table 59 (Maps 59A and 59B) (KP 1064.2 - 1076, end of pipeline route): North-East of Sagirlar Settlement to the End of the Pipeline Route, Adana Province

BASELINE	POTENTIAL IMPACTS	MITIGATION	RESIDUAL IMPACTS
site, dating back to the Roman period. • Kurtkulagi Pasture (1st Degree Site*) – this is a megalithic monument. This type of monument is documented for the first time in this region. * These sites have not yet been registered by the MoC and are provisionally assigned these classifications. Gokdere and Kurtkulagi have been proposed for registration by the regional preservation council	from construction activities that will affect the visual/historical setting of these sites.	route is possible. Specific mitigation to be developed following site investigations. The pipeline has been re-routed to avoid Kurtkulagi Pasture. Potential impacts will therefore be avoided. Maltepe South will be fenced throughout the construction period to avoid accidental damage Construction will be carried out under the supervision of an archaeologist authorised BOTAŞ.	further investigation prior to construction. As further field investigations are expected to find a re-route to avoid this site, the ultimate scale of impact is likely to be minor and short-term in duration. **MINOR IMPACT** Assuming Maltepe South is fenced, impacts will be limited to the temporary disturbance of the site setting and peripheral features. **MINOR IMPACT** Impacts will be limited to the temporary disturbance of the site setting of Kurtkulagi Pasture and peripheral features.

Social Impact Table 59 (Map 59C) (KP 1064.2 – 1076.2, end of pipeline route): North-East of Sagirlar Settlement to the End of the Pipeline Route, Adana Province

MAP 59: PROJECT INFORMATION

There are no pump stations, construction camps or block valve stations in the area.

MAP 59: MAP HIGHLIGHTS

- Major land use is rain-fed agriculture, some pasture and irrigated agriculture.
- The pipeline crosses two unclassified roads and the Kalebogazi river.
- The Yuceoren Quarter lies within the corridor to the west of the route.
- Two Energy Transmission lines bisect the pipeline.
-

MAP 59: IMPACTED & SURVEYED SETTLEMENTS

- ***Impacted:*** seven settlements (Akpinar/ Kurtpinar, Kurkulagi, Tatarli, Sevkiye, Veysiye, Abdiye, Sarimazi) will be directly impacted by the pipeline project; all of these have land intersected by the proposed pipeline (L); no settlements are within 5km of a pump station and one settlement (Vesiye) is within 500m of the pipeline route (D). Settlements impacted by traffic have not yet been identified. There are no settlements downstream of a river/ creek crossing.

Surveyed: three settlements (Akpinar/ Kurtpinar, Kurkulagi, Catakli) were surveyed in the field (S) and six settlements (Tatarli, Sevkiye, Veysiye, Abdiye, Sarimazi, Burhanli) were surveyed by telephone (T).

- ***Not surveyed:*** Sagirlar (850m from the pipeline) and Barikecli.
- ***Not on map:*** Tatarli, Sevkiye, Veysiye (550m from the pipeline), Abdiye (1.25km from the pipeline), Catakli (2km from the pipeline) and Burhanli (1.2km from the pipeline).
- ***Disclosure Meeting Location:*** Akpinar

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Akpinar (Kurtpinar) (L) (S)			
• ***Demographics:*** 2,000 inhabitants with 550 households. Increase in population due to BOTAŞ and Toros Fertiliser facilities. The Settlement includes two neighbourhoods (both surveyed as part of the marine terminal baseline. These include the Karatepe neighbourhood (500 population, 80 households), Incirli neighbourhood (500 population, 100 households). • ***Safety:*** the settlement centre is 1.7km from the pipeline and the nearest house is 1km. Karatepe is within a few meters of oil storage tanks, and inhabitants are concerned about odour and fire outbreak. • ***Health:*** contagious diseases occur occasionally. • ***Project attitude:*** a construction camp would be welcome, there is	***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production.	**Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction	**No significant impacts** predicted if dust suppression and monitoring measures are fully implemented.

Social Impact Table 59 (Map 59C) (KP 1064.2 – 1076.2, end of pipeline route): North-East of Sagirlar Settlement to the End of the Pipeline Route, Adana Province

general awareness about the project although the attitude is predominantly negative, especially in Karatepe and Incirli where they have lost most of their livelihood including fishing, agriculture and pasture land due to previous projects. However, they do have expectations of jobs. • ***Land ownership & use:*** 17% of land is owned by local residents and 60% of land is communal. Karatepe and Incirli neighbourhoods lost all land in previous project expropriations. The key crops are grain, vegetables, cotton and watermelon. There is seasonal grazing in the summer and October. There is no irrigation. • ***Settlement livelihood:*** animal breeding is the main source of income. Other livelihoods include agriculture (soil is fertile), animal husbandry (cattle, sheep, goats, poultry), fishing, construction, trade and tourism. 7% of inhabitants are unemployed (for less than one year), 4% are unemployed (for more than one year), 3% have regular paid jobs, 1% are seasonal labourers and 25% are family labourers. Incirli has lost fishery as an income due to prevention of fishing in the BOTAŞ area. Both neighbourhoods need jobs. • ***Availability & skills:*** previous experience (Iraq-Ceyhan-Kirikkale pipeline). 10 out of 24 construction skills including a machine technician. There are a high number of experienced workers. 55% of inhabitants are willing to take on temporary jobs. There is also an inoperative stone quarry. • ***Accessibility:*** the settlement is accessible all year round and the distance from the settlement to the district centre is 18 km. • ***Information provision:*** Literacy rate is 85%. Local sources of information are TV, family, friends, Muhtar and the national sources are TV, radio, paper and the Muhtar. • ***Environmental & cultural sites:*** civilian architecture. • ***Services:*** phone and mobile networks, coffee houses, market and transport. There is a school, but there are no health facilities, except for traditional methods. Health facilities of Kurtkulagi town (4-5km) are used. • ***Infrastructure:*** there is piped water, although the supply is irregular. There is no alternative water source. Electricity is present. There are	***Construction hazards animals:*** Trench poses safety hazard for livestock. ***Land*** Potential complications in expropriation process. ***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2km downstream of a river crossing. ***Skills and Resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials.	**Livestock crossings** will be established at locations agreed with the community. Stock proof fencing will be erected in areas of danger for livestock. **See Overview of the Land Acquisition Process in Appendix C9.** **Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where necessary. The level of compensation will be facilitated by the Projects complaints procedure. **Information is highlighted to Contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and supplies within project constraints.	**Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of the Land Acquisition Process in Appendix C9.** **No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full. **Potential positive benefits** to local settlements.

Social Impact Table 59 (Map 59C) (KP 1064.2 – 1076.2, end of pipeline route): North-East of Sagirlar Settlement to the End of the Pipeline Route, Adana Province

There is no alternative water source. Electricity is present. There are no sewerage systems. Waste systems are present eg waste is collected by trucks. • ***Settlement problems:*** poor water quality, unemployment, water shortage, lack of sewer system, lack of health facilities.	***Health*** Potential health impacts on construction workers	**Information is highlighted to Contractor** so that they can ensure that their workers are protected.	**No residual impact.**
SITE SPECIFIC CHARACTERISTICS	**ADDITIONAL IMPACTS**	**ADDITIONAL MITIGATION**	**RESIDUAL IMPACTS**
Kurtkulagi town (L) **(S)**			
• ***Demographics:*** 3000 inhabitants with 450 households, there has been no change in population. 25% of inhabitants migrate to the Iskenderun-Payas region for employment and to the province and district centre for education. Seasonal workers also come to work in the town. • ***Safety:*** the settlement centre is 2km from the pipeline, and the nearest house is 1.6km. Occasional fires take place and are put out by fire extinguishers. • ***Disputes:*** minor land conflicts. • ***Project attitude:*** there is a general awareness of the project but the inhabitants want more information. The overall attitude is neither positive nor negative. Key benefits perceived are direct employment by 80% of the inhabitants, land compensation by 10% and indirect employment by 10%. There are some safety concerns. • ***Land ownership & use:*** 30% of land is owned by local residents and 40% of land is state owned. There are problems with title deeds and inheritance issues. There is temporary irrigation, and the key crops are grain, vegetables, cotton, fruit trees and grapes. • ***Settlement livelihood:*** agriculture, animal breeding (goats), beekeeping, transport, trade, education and tourism. 10% of the inhabitants are unemployed (for less than one year), 6% are unemployed (for more than one year), 2% have regular paid jobs and 27% are family labourers. • ***Availability & skills:*** there is previous experience, the Iraq-Ceyhan-Kirikkale pipeline passes 1km at the south of the town. 9 out of 24	***Conflicts over land boundaries*** Exacerbation of existing conflicts. ***Sensitive vegetation used by bees*** Dust may affect yields of vegetation (eg grey clover) essential for nectar production. ***Construction hazards animals*** Trench poses safety hazard for livestock. ***Land*** Potential complications in	**Land boundaries to remain clearly demarcated** at all times. **Effectiveness of dust suppression** methods to be monitored daily and increased if necessary. **Community liaison meetings:** issue to be discussed at meetings before and during construction. **Livestock crossings** will be established at locations agreed with the community. **Stock proof fencing** will be erected in areas of danger to livestock. **See Overview of the Land Acquisition Process in**	**No significant residual impacts.** **No significant impacts** predicted if dust suppression and monitoring measures are fully implemented. **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **See Overview of the Land Acquisition Process in**

Social Impact Table 59 (Map 59C) (KP 1064.2 – 1076.2, end of pipeline route): North-East of Sagirlar Settlement to the End of the Pipeline Route, Adana Province

construction skills including engineers, heavy vehicle drivers, heavy machinery operators, and qualified workers in the construction of utility infrastructure. 73% of inhabitants will accept a temporary job. There is also an inoperative stone quarry. • ***Accessibility:*** the settlement is accessible all year and the distance from the settlement to the district centre is 14km. • ***Information provision:*** Literacy rate is 99%. Local sources of information are TV, family, friends, Muhtar and the national sources of information are; TV, radio, newspapers and the Muhtar. • ***Environmental & cultural sites:*** Kazankeys site, civilian architecture, religious buildings, grave and a nursery. • ***Services:*** post office, transportation and agricultural credit cooperative. There is a primary school with 12 teachers and 207 students. In addition, 100 students are transported 14km to Ceyhan for high school education. There are health facilities including a midwife, health centre, doctor, and a nurse. • ***Infrastructure:*** there is a piped regular supply of water. There is no problem with drinking water due to recent construction of new wells. Electricity, sewerage systems and waste systems are present. • ***Settlement problems:*** unemployment, poverty, sewerage system not sufficient.	expropriation process. ***Irrigation*** Potential loss of flow from planned/ accidental disruption. Potential contamination of flow from spills or increase in sedimentation. ***Accessibility to recruitment*** Decreased access to recruitment process. ***Skills and Resources*** Increased opportunity to provide skilled or semi-skilled labour or to source goods or materials.	**Appendix C9.** ***Groundwater*** During land acquisition, any ground water within 50m of the working width and 100m down slope of the working width to be identified. **In event of a spill** settlement to be immediately warned and alternative sources of water to be provided. Contractor will **consult** with authorities to determine maximum acceptable time for disruption. Winter road closures, seasonal migration and poor transport will be **taken into account** in the recruitment strategy **Information is highlighted to Contractor** so that they can ensure that directly impacted settlements are given preferential treatment in recruitment and in sourcing of goods and	**Appendix C9.** **If there is any long term impact on water sources**, appropriate alternatives to be provided by the Project. **If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. **No residual impact expected.** **Potential positive benefits** to local settlements

decrease in cotton production recently due to a plant disease. Citrus fruits have been recently cultivated. Other settlement livelihoods are construction, transport and education. 7% of inhabitants are unemployed (<year), 4% are unemployed (>year), 1% have regular paid jobs, 1% are seasonal labourers and 30% are family labourers. • ***Availability & skills:*** there is no previous experience, although a few inhabitants have experienced infrastructure projects. 7 out of 24 construction skills including heavy vehicle drivers, heavy machinery operators and construction workers, the inhabitants seem to be very qualified in each area. 100% of the inhabitants are willing to take on temporary jobs. In addition there are abundant local sources of sand and pebbles. • ***Accessibility:*** the settlement is accessible all year. The settlement is 6km from the district centre. • ***Information provision:*** Literacy rate is 99%. Local information sources are TV, family, friends, Muhtar and the national sources are TV, radio, paper, and the Muhtar. • ***Services:*** there are no schools and facilities of neighbouring Tatarli settlement are used. There are no settlement health facilities, the inhabitants use the Mustafeybeyli town health facilities. • ***Infrastructure:*** there is piped water although the supply is affected by electricity cuts. There is no alternative water source. Water is sourced from this settlement and Tatarli settlement and is used by 30 other settlements in the neighbourhood. There are no sewerage systems present. There is a waste system, but source of waste disposal is not known. • ***Settlement problems:*** unemployment, low income, poverty. Inhabitants are unable to pay debt to Agricultural Credit Cooperative. Lack of sewerage, education, lack of health facilities and frequent electricity cuts.			

Social Impact Table 59 (Map 59C) (KP 1064.2 – 1076.2, end of pipeline route): North-East of Sagirlar Settlement to the End of the Pipeline Route, Adana Province

SITE SPECIFIC CHARACTERISTICS	ADDITIONAL IMPACTS	ADDITIONAL MITIGATION	RESIDUAL IMPACTS
Burhanli (T)			
• ***Demographics:*** 890 inhabitants. There is no seasonal migration • ***Safety:*** settlement centre is 1.2km from the pipeline, the nearest house is 650m from the pipeline. • ***Disputes:*** problems rarely occur and are resolved with the help of the settlement headman and elders. The settlement headman is very influential. • ***Project attitude:*** a construction camp would be welcome. There is awareness about the pipeline, the general attitude is positive and there are no major concerns.	***Construction hazards: humans*** Working areas pose safety hazard to residents, particularly small children	**Road safety training will be held** in schools prior to construction commencing. **Community liaison meetings held** prior to and during construction will include safety briefings.	**Continued attention** to mitigation measures will be critical to prevent injury. **Benefits** from health and safety awareness raising.
• ***Land ownership & use:*** 70% of land is privately owned, although 15 households do not have title deeds which are issued in the names of their heirs. There is no seasonal grazing. There is temporary irrigation and the key crops are wheat, soybeans, corn and cotton. • ***Settlement livelihood:*** agriculture is the main source of income, animal breeding is for subsistence and sheep breeding by some families is for commercial purposes (sacrificial sheep). Transport, trade, education are other livelihoods sources for the settlement. 25% of inhabitants have regular paid jobs and 65% are family labourers. There is fishing (three households, one of many sources of income), bee keeping (one household, one of many sources of income) and also hunting. • ***Availability & skills:*** there is no previous experience of a pipeline project. • ***Accessibility:*** the settlement is accessible throughout the year. • ***Information provision:*** literacy rate is 99%. Main local sources of information are TV, family, friends, Muhtar and the main sources of national information are; TV, radio, newspapers and the Muhtar • ***Environmental & cultural sites:*** Uzun Ahmets's traces, caves. • ***Services:*** there is a school but with only one teacher, which is insufficient, 60 students use the facilities at Tartali settlement. There are four groceries. There is also a settlement clinic, a doctor, a health	Land beyond that compensated for may be affected if mitigation measures not fully implemented. ***Construction hazards: animals*** Trench poses safety hazard for livestock. ***Fishing*** Potential reduction in fisheries yield or damage to fisheries habitats within 2km downstream of a river crossing.	**Community liaison meetings will be held** during and immediately following construction to identify any additional land that has been affected. **Livestock crossings** to be established at locations agreed with the community. **Stock proof fencing** to be erected in areas of danger for livestock. **Fisheries mitigation measures** including: verification of fisheries, fish characterisation, implementation of habitat restoration measures and compensation where	**Any additional damage to be compensated for** **Potential for accidents involving livestock.** Financial compensation will be given. The level of compensation will be facilitated by the Projects complaints procedure. **No significant impacts** if there is compensation for any reduction in yields, and if habitat restoration measures are implemented in full.

The level of compensation will be facilitated by the Projects complaints procedure.	**If irrigation water is disrupted** longer than time considered acceptable by authorities, or if there is unexpected loss of flow, affected land-users will be compensated. Significance cannot be established at this time.

12 MARINE TERMINAL - ONSHORE IMPACTS AND MITIGATION

12.1 INTRODUCTION

12.1.1 Basis for the assessment

This section identifies the terrestrial impacts associated with the construction, commissioning and operation of the onshore BTC Marine Terminal (including tank farm and jetty facilities). It assesses their significance in light of mitigation measures incorporated into its design and management. Where appropriate, specific control measures are described in greater detail.

The potential impacts have been derived through scoping and consultation activities and also through applied professional judgement. Assessment criteria on which professional judgement is based are detailed in Section 3 of this report.

12.1.2 Scoping

Preliminary details concerning the existing environmental baseline were established during initial scoping activities undertaken between September 2000 and January 2001. This overview highlighted potential areas of concern and established the need for areas of further investigation. Potential areas of concern included the following ecologically important areas.

- Coast near Golovasi (approximately 1.5km west of the proposed jetty location). The globally threatened Loggerhead Turtle (*Caretta caretta*), classified by IUCN as endangered, is known to nest on this stretch of coastline.

- Yumurtalik Lagoons Nature Reserve (approximately 20km southwest of the proposed terminal location). This reserve represents the only known wintering area in the Mediterranean of the globally threatened Green Turtle (*Chelonia mydas*) classified by the IUCN. This site is also important for internationally important populations of breeding birds.

No other areas of significant environmental concern associated with the marine terminal were identified through this initial scoping exercise. However, during the consultation, commencing in August 2001, a number of additional perceived benefits and concerns were raised. These issues varied between stakeholders (from local residents to NGOs and local authorities), but generally included the following:

Perceived benefits of the BTC Marine Terminal:

- generation of employment;
- contribution to regional development;
- improvement of infrastructure;
- improvement of regional security services.

Perceived negative impacts of the BTC Marine Terminal:

- decreased access to fishing grounds;
- increased traffic congestion during construction;
- increased pollution;

- generation of health and safety issues;
- potential for future expansion onto adjacent agricultural land;
- potential for future in-migration leading to pressure on local resources and infrastructure and services.

12.1.3 Potential impacts

While the possible interactions between the proposed terminal and terrestrial receptors are numerous, mitigations inherent in the design, combined with the relatively low number of sensitive receptors means that the potential impacts associated with the development of the proposed marine terminal facilities are limited in scope. The potential impacts identified in scoping, consultation and the EIA process in general are summarised in Table 12.1.

Table 12.1 Potential Impacts

MAIN ACTIVITIES	POTENTIAL IMPACTS
Construction	
• Land clearance • Construction traffic • Construction activity • Alteration to drainage regime • Establishment and enforcement of Security Exclusion Zone and Manoeuvring Area	• Temporary and permanent habitat loss • Habitat disturbance • Impacts to traffic and transport • Noise and light impacts to humans • Noise and light impacts to ecology • Landscape and visual impacts • Impacts to surface and groundwater quality • Impacts to air quality from dust and vehicle emissions • Soil compaction • Impacts to cultural heritage through construction disturbance • In-migration • Impacts from construction workers • Safety risks to neighbouring settlements • Employment, sourcing of local goods and skills training • Secondary impacts to livelihoods due to decreased access to fishing grounds • Decreased suitability for tourism activities • Disruption to infrastructure and services
Operation	
• Physical presence of marine terminal facilities • Operation of terminal facilities • Vehicle movements associated with terminal operation • Flaring • Alteration to drainage regime • Ongoing enforcement of Security Exclusion Zone and Manoeuvring Area	• Displacement of flora and fauna • Impacts to traffic and transport • Noise and light impacts to humans • Noise and light impacts to ecology • Landscape and visual impacts • Impacts to water quality • Impacts to hydrology • Impacts to air quality from flaring • Impacts to cultural heritage • Employment, sourcing of local goods and skills training • Secondary impacts to livelihoods due to decreased access to fishing grounds • Potential risk to environmental and social resources from oil spill (addressed in Section 14)

12.1.4 Structure of this section

The remainder of this section is organised as follows:

- soils;
- landscape and visual;
- surface and ground waters;
- geological environment;
- air quality;
- noise;
- traffic and transport;
- cultural heritage;
- demographics and migration;
- resource ownership and use;
- employment, livelihoods and skills;
- infrastructure and services.

12.2 SOILS

12.2.1 Introduction

This section identifies the potential for impacts to soils as a result of the construction and operation of BTC Marine Terminal. Impacts to soils have been identified when an activity results in a change to the existing soil conditions. Potential impacts to soils broadly fall into the following categories:

- soil compaction;
- loss of soil resource;
- soil contamination and solid waste handling and disposal.

Secondary impacts, which result from changes in soil conditions, have also been identified (eg changes to local hydrology). The significance of impacts has been determined using a suite of impact significance criteria, which are set out in Section 3 of this report. Mitigation measures have been identified and are also presented in this section.

The generation, storage, handling and disposal of solid wastes can have implications to several environmental aspects other than soil but is dealt with in this section since the primary receptor to impact is usually land.

12.2.2 Construction impacts and mitigation

12.2.2.1 Storage tanks, general facilities and accommodation

The terminal will be constructed on prepared ground. The underlying geology comprises igneous basalt rock.

Terminal site preparation will involve site levelling, which will result in the disturbance and compaction of soils in the vicinity of the proposed facilities. A number of best practice soil management measures will be used to ensure that compaction impacts are minimised. These measures are described in the Reinstatement Plan (Appendix C2).

Soil compaction, as well as progressive changes in the areas of hardstanding as the various facilities are built, will result in localised changes to the local drainage regime. This will alter

runoff and infiltration patterns, but given the very low rainfall, secondary impacts are considered to be minor.

Impacts to soils during construction will be minimised by the mitigation measures listed below.

- Compaction will be minimised during soil stripping use of appropriate machinery.
- Top and subsoils will be stripped, stored and replaced separately and any parent material removed.
- Topsoil that is removed from locations that are to become hardstanding and/or covered by a permanent structure will be removed and stored for later use in landscaping of the site.
- Soil stockpile heights will be restricted to a maximum of 2m to prevent compaction under the weight of the soil.
- Measures to reduce the mobilisation of silt from soil stockpiles will be taken, such as covering stockpiles.
- Any compaction in the construction areas or in other areas that might affect agricultural restoration will be relieved (for example by subsoil ripping).
- The beach profile will be restored to its pre-construction status.
- Arrangements will be made for the aftercare of the construction area.
- Purpose designed drainage procedures will be used.

Other measures will include the avoidance, wherever practicable, of areas of sensitive soils for use as storage facilities etc.

12.2.2.2 Loading lines to the jetty

The loading lines from the tank farm to the BTC Jetty cross some small areas of agricultural land. The loading lines pass through areas of Class III and Class VII Soil Capability (described in Section 10). As these soil types are not especially sensitive in terms of their potential for agricultural development, and the impacts from the installation of the loading lines are localised, impacts are anticipated to be minor. Any standing crops present will be cut, baled and removed from the construction areas and up to 1m outside the construction area. Should the owner/occupier not require the crop, the material would then be disposed of in accordance with Turkish legislative requirements. The siting of construction areas will take into account the nature of any crop and proximity to orchards will be avoided.

Topsoil stripping and storage for the loading line corridor will be undertaken in line with best practice methods described in the Reinstatement Plan (Appendix C2).

The loading line trench will be backfilled with the previously excavated spoil, which has been stored for that purpose. This will most likely be done with the help of backhoes/dozers. After clearing and removal of all material and waste, the topsoil, which has been stockpiled separately, will be replaced over the working corridor.

The causeway footing will be constructed on rock therefore anticipated impacts to the beach sediments and the beach profile will be minor at most.

12.2.2.3 Managing spills

Spills of fuel and lubricant oils will be prevented by ensuring that all fuel storage areas are located in secure bunded areas. Wherever possible, fuel handling will also take place in secure bunded areas. Adequate supplies of skimmers, dispersants and absorbent material will be available at all fuel storage and handling areas to cope with terrestrial spills as part of the Pollution Prevention Plan. Similar conditions will apply to lubricant oils, chemicals and liquid wastes. Should a spillage occur, contaminated soils would either be cleaned up or removed for appropriate disposal in accordance with Turkish legislation and World Bank standards. Guidance for the cleanup of contaminated soils is included in the Environmental Management and Monitoring Plan (Appendix C1) and the Waste Management Plan (Appendix C3).

12.2.3 Operational impacts and mitigation

12.2.3.1 Storage tanks, general facilities and accommodation

During normal operation, long term changes in soil function will be caused by the presence of new areas of hardstanding and the operational activities associated with them. The tanks will be located on soils with non-sensitive soil capability classes (Class III and Class VII). Soil retained from the hardstanding and the construction of these areas will be used in landscaping (see the Reinstatement Plan - Appendix C2).

During operation, general wastes (that is all other non process unit derived waste) will be produced from the offices, battery rooms, fire stations/garage, workshops, as well as from general maintenance generating material such as scrap wood and metal. Inadequate disposal of such wastes has the potential to cause contamination to soils.

There are currently several options for the disposal of solid wastes. The scope for incineration of combustible wastes will be investigated during the construction phase. Wastes that cannot be incinerated will be disposed of off-site by a licensed waste contractor. Potentially hazardous materials (eg paints, batteries etc) will be disposed of by a specialist contractor to a licensed site. Landfill disposal could be in existing (third party) landfill facilities constructed along the pipeline route specifically for the waste for the construction project. Impacts due to potential contamination from solid waste will therefore be minor at most.

12.2.3.2 Loading lines

Once reinstatement of the loading lines has been completed, recovery of the affected area is expected to be rapid. Long term impacts to soils are anticipated to be minor.

Nevertheless, especially in slopes, particular attention will be paid to implementing measures for land drainage and erosion control. Land drainage and erosion control issues are addressed in detail in Appendix C2.

12.3 LANDSCAPE AND VISUAL

12.3.1 Introduction

This Section identifies the landscape and visual impacts associated with construction and operation of the BTC Marine Terminal.

The methodology and criteria for assessing and determining the potential landscape and visual impacts is set out in Section 3. A discussion of the landscape and visual impacts and their

significance is presented in Sections 12.3.2 and 12.3.3 respectively. Mitigation measures are also included as appropriate.

12.3.2 Magnitude of landscape impacts

Operational impacts to landscape will arise predominantly through a combination of landscape features lost during construction and from the introduction of the facilities associated with the proposed marine terminal (tank farm, accommodation etc). It should be noted, however that many of the components of the proposed marine terminal will not be alien to the landscape due to the presence of the existing marine terminal facility, which acts as an industrial backdrop from many key viewpoints (eg the settlement of Kurtkulagi).

Some elements of the proposed terminal facilities, notably the loading lines, have no operational landscape impacts as they are subterranean.

A summary of the impacts on landscape for the operational phase is presented in Table 12.2.

Table 12.2 Landscape Impacts and Evaluation of Significance

FACILITY	RECEPTOR	RECEPTOR SENSITIVITY	MAGNITUDE OF IMPACT	SIGNIFICANCE (RESIDUAL IMPACT)
Tank farm	Elevated scrubland	Low	Moderate	Minor
Tank farm	Pine woodland – one tank would lead to the loss of some trees, which are in the possession of BOTAŞ	Moderate	Moderate	Moderate
General facilities and accommodation	Low lying scrubland	Low	Moderate	Minor
Jetty	Foreshore and beach area	Moderate	Moderate	Moderate

Landscaping, bunding and planting for areas of the site will mitigate impacts to some extent but will not address the jetty affect on the coastal landscape. It will, however, offset the moderate impacts resulting from the loss of some pine woodland, which is in the possession of BOTAŞ.

12.3.3 Visual impacts

12.3.1.1 Construction impacts

The impacts during construction are similar in nature to those identified during operation (see Section 12.3.1.2). The main receptors include local residents, BOTAŞ personnel, potential tourists, users of the main coastal roads and fishermen.

Some receptors are likely to be more susceptible than others during the construction phase, in particular, people that live along the sides of the access roads to the site and residents with a view of the site who will be subject to visual disturbance. Some areas in close proximity to the existing facilities may be screened by the existing facilities. Furthermore, construction impacts are temporary and thus potentially less severe.

Impacts during construction will be primarily mitigated through the limitation of the construction area to the minimum required for construction purposes in response to identified local sensitivities.

12.3.1.2 Operational impacts

Receptors that may be disturbed during operation include:

- local residents at settlements with both short-distance views (eg, Sahil Sitesi) and those with longer distance views (Kurtkulagi, Hamzali, Golovasi);
- BOTAŞ personnel at the existing facilities (both those living/working at the terminal and those using the leisure facilities which BOTAŞ operates for its nationwide staff);
- potential tourists and holiday home owners (eg Sahil Sitesi, Incirli, Golovasi and the BOTAŞ tourist facilities);
- users of the main coastal roads to Yumurtalik etc;
- fishermen.

Various receptors are likely to be more susceptible than others, depending on the visual aspect and scale of visual intrusion. Even in a given settlement, some households may have unobstructed views of the new facilities while others may have no view at all. Furthermore, some areas in close proximity to the existing facilities (eg the settlement of Karatepe) will effectively have no views of the new facilities due to screening by the existing tank farm (see Plate 12.1).

Views of the terminal will be partially screened by mitigation planting and the growth of existing intervening vegetation. In addition the removal of matured trees will be minimised.

Plate 12.1 Existing BOTAŞ Tank Farm and Karatepe Settlement

12.3.1.3 Zone of Visual Influence

The Zone of Visual Influence (ZVI) for the proposed marine terminal site at Ceyhan identifies the extent to which the facilities will be visible to surrounding receptors (see Figure 12.1).

The ZVI extends away from the coast and inland, although the landward spread is limited by the hilly landscape west of both Kurtkulagi and Hamzali.

Many of the surrounding settlements will be within viewing distance of the new tank farm, accommodation block, general facility area and jetty. These settlements include much of Kurtkulagi, the southern and eastern borders of Hamzali, the southern outskirts of Golovasi and the northern borders of Incirli. The southern outskirts of Karatepe settlement may be within view of the proposed facilities, although much of this will be screened by the existing tank farm. However, the ZVI for the proposed terminal lies within the footprint of the visual influence of the existing BOTAŞ site and therefore these settlements will already experience views of the area.

The existing Incirli and BOTAŞ beach tourist facilities are located within an existing industrial context, with tourism continuing regardless. As a result, the development of the marine terminal is not expected to impact tourism in these two sites. Sahil Sitesi is characterised by a sense of peacefulness, seclusion and natural beauty, in spite of the view of the jetty, less than 3km away, which attracts the high number of secondary homeowners (approximately 150) and other tourists. In terms of visual impacts, this is the only settlement that is likely to experience major visual intrusion from the marine terminal development. The potential impacts to tourism are discussed in Section 12.10.3.

During operation of the new terminal, the Enclosed Ground Flare (EGF) will be visible from parts of Sahil Sitesi. It is predicted that the visual impact to the receptors identified will be minor (see Figure 12.1).

Various different visual receptors will be affected by the longer term existence and operation of the onshore facilities (including jetty and EGF). The overall significance of visual impacts is summarised in Table 12.3.

Table 12.3 Visual Impacts and Evaluation of Significance – Operation

RECEPTOR	RECEPTOR SENSITIVITY	MAGNITUDE OF IMPACT	MITIGATING FEATURES	SIGNIFICANCE (RESIDUAL IMPACT)
Workers at existing BOTAŞ facilities	Low	Moderate	Existing industrial context	Minor
Recreational users at existing BOTAŞ facilities	Moderate	Moderate	Existing industrial context	Moderate
Residents at Golovasi	High	Low	Screening by terrain and vegetation	Moderate
Residents at Hamzali	High	Low	Screening by terrain and vegetation and backdrop of existing facilities	Moderate
Residents at Kurtkulagi	High	Low	Backdrop of existing facilities	Moderate
Residents at Incirli	High	Low	Backdrop of existing facilities	Moderate
Residents at Karatepe	High	Low	Screened by existing facilities	Moderate

RECEPTOR	RECEPTOR SENSITIVITY	MAGNITUDE OF IMPACT	MITIGATING FEATURES	SIGNIFICANCE (RESIDUAL IMPACT)
Residents at Sahil Sitesi	High	High	Screening by terrain and vegetation (main facilities). Backdrop of existing facilities (jetty)	Major
Road users	Low	Moderate	Transient view	Minor
Fishermen	Low	Moderate	Transient view and backdrop of existing facilities	Minor

Indicative photomontages of the BTC Marine Terminal from three different view points are presented in Plate 12.2 – Plate 2.4.

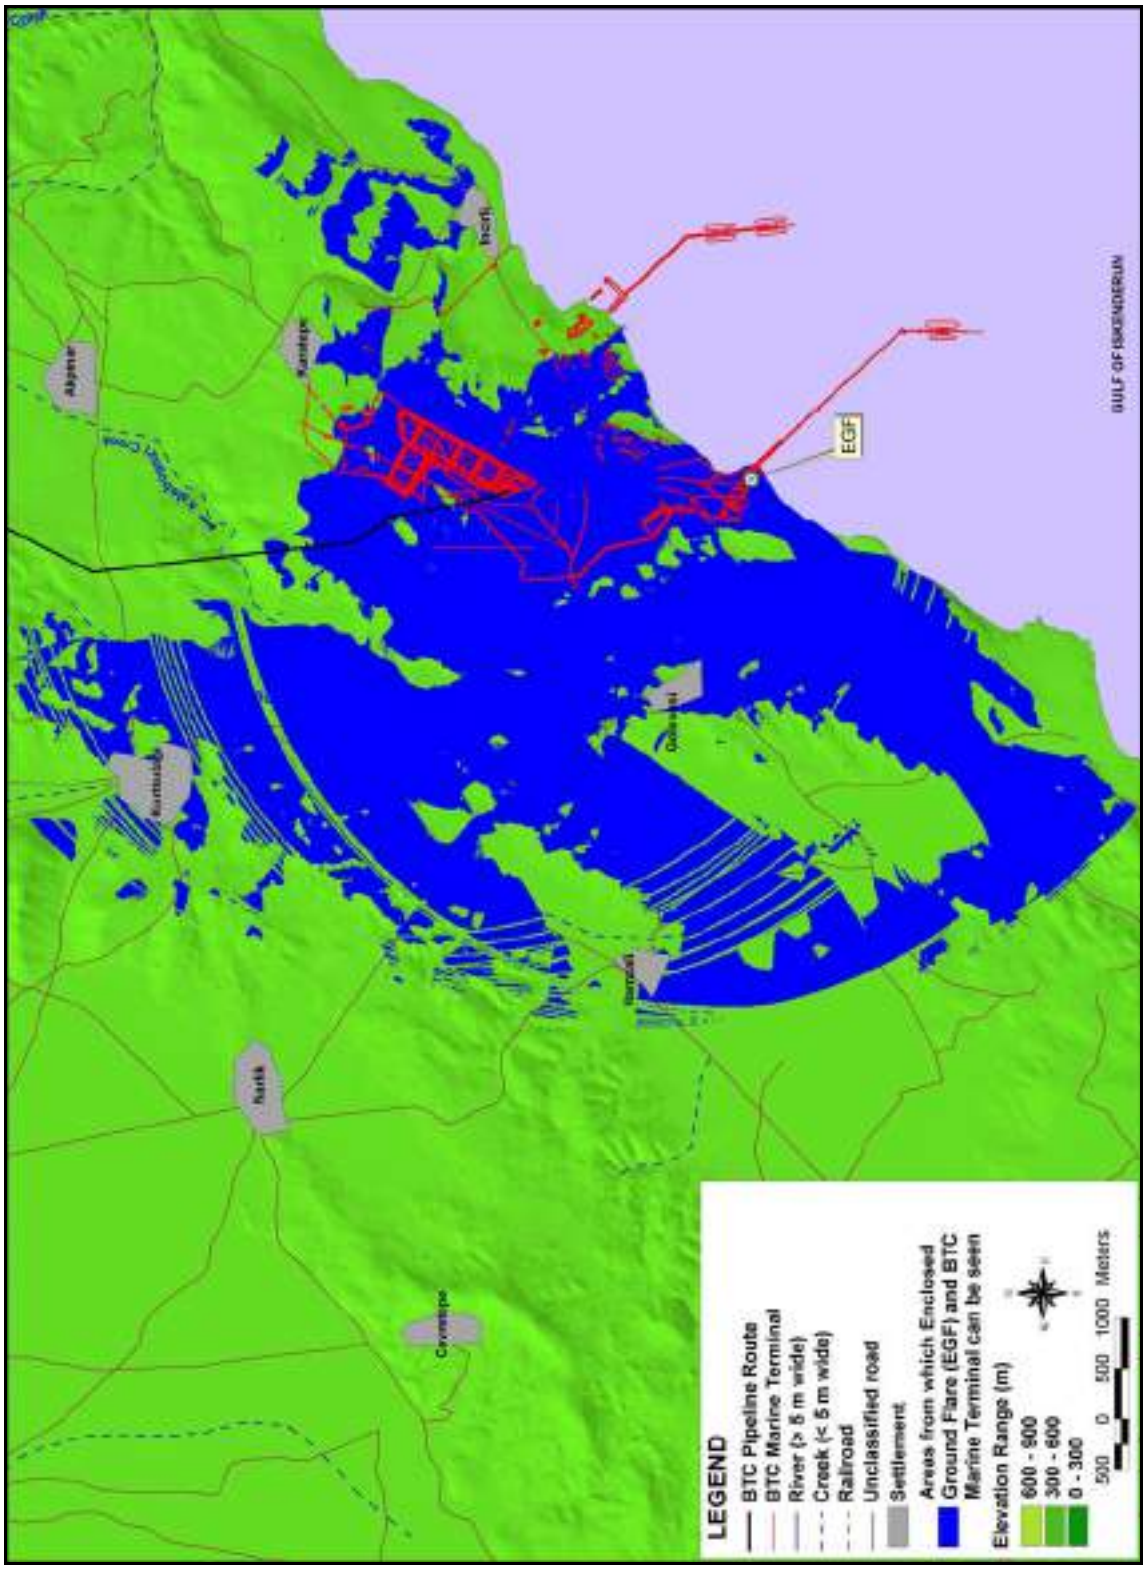

Figure 12.1 Zone of Visual Influence of BTC Marine Terminal and EGF

Plate 12.2 General View of the BTC Marine Terminal from Sahil Sitesi (Observation Point 1)

Plate 12.3 General View of the BTC Marine Terminal from Golovasi (Observation Point 2)

Plate 12.4 General View of the BTC Marine Terminal from Sahil Sitesi (Observation Point 3)

12.3.4 Mitigation

The mitigation strategy that will be employed to limit the extent of landscape and visual impact of the terminal will need to accommodate the varying characteristics of its component elements and the nature of the impacts associated with each.

The new tank farm will be particularly visible, especially at viewpoints to the north and west. Any opportunities to screen these structures risks accentuating their prominence by drawing attention to them. As skyline features, opportunities to provide comprehensive screening will be limited. Mitigation measures will focus instead on de-emphasising their apparent bulk. For example, sparse tree cover on the slopes below the existing tanks to the north and west helps to disrupt views of them. In the same way, clumped naturalistic tree planting will be introduced on the slopes at the base of the new tanks to the same effect. Any opportunities to employ landform screening (eg bunds) will be taken, so long as it can be integrated with existing landform features. This will ensure that any recognisable features at ground level, such as huts or vehicles, which might otherwise confirm the scale of these structures, are obscured. Planting schemes will utilise native species present on site in associations and densities similar to those of existing stands. This will ensure that the planting scheme blends harmoniously with the existing landscape and provides continuity of habitat. Furthermore, secondary ecological impacts associated with the introduction of alien species are thus avoided.

It is proposed that a mixture of shrubs and trees be planted at a spacing of approximately 1.5m for shrubs (eg hibiscus, oleander, myrtle) and 3.0m for trees (eg pine, olive or citrus). Trees and shrubs will be planted in irregular lines to provide a natural appearance in keeping with the surrounding landscape.

From the south, the new tanks will present a shortened profile. In addition, plantation woodland on intervening slopes helps to visually tie the tanks into the landscape. Some extension of this woodland may be needed to extend this effect so that it accommodates the new tanks. Other mitigation of the tank farm will concern the alignment and finish of the tanks. If feasible the tanks should be aligned to reduce the distance between them so that they appear as far as possible as a unified structure rather than (as it is) several different structures. In addition, the tanks' surfaces will be finished to emulate both the greys of the native soil and the colour of the existing tanks, again to help tie them visually into the landscape.

The other land-based facilities (housing compound and office compound), being much smaller, will employ more traditional mitigation, particularly using tree and shrub planting both at perimeter and, more importantly, within the compound. This will create a more pleasant environment for their users as well as landscape mitigation for the sites as a whole. Planting schemes will be devised to reflect existing planting in the locality and will avoid linear tree screens.

The new jetty presents limited opportunities for visual mitigation. Its structural appearance will be governed by practical needs although low-bulk designs, where feasible, would be favoured. Principal visual impacts from this structure will affect the residents and other occupants at the site-facing edge of Golovasi and Sahil Sitesi. If pertinent and appropriate, off-site screening will be provided at affected properties.

12.4 SURFACE AND GROUND WATERS

12.4.1 Introduction

This section identifies the potential for impacts to surface and groundwater resources as a result of construction, commissioning and operation of BTC Marine Terminal. Impacts to water resources have been identified when an activity is predicted to result in a change to the baseline situation. The significance of the impacts has been determined using the impact significance criteria set out in Section 3 of this report. The significance of any potential impact on surface water quality will ultimately depend on the use of the resource (eg for fishing, bathing, drinking supply) or its importance to ecology or amenity and the magnitude of the change caused by the project. The significance criteria are largely based on World Bank and Turkish standards (see Appendix D) for each category of impact. Where no standards are available, professional judgement has been used.

Mitigation measures have been identified and details are presented in this section.

12.4.2 Construction and commissioning impacts

12.4.2.1 Scope of impact

The BTC Marine Terminal is located on basalt rock. An unconfined aquifer is located approximately 1.4km to the south. Surface water features comprise ephemeral watercourses appearing only during periods of high rainfall. The principal impacts of construction and commissioning relate to groundwater and marine receiving waters. The potential for impacts to surface waters is low.

Impacts to groundwater may arise from changes in infiltration and runoff patterns due to compaction or increased hardstanding during construction. In addition, potentially contaminated drainage streams may pollute groundwater if not properly treated and disposed of. Construction mitigation measures described in Section 12.4.2.2 have been designed to minimise impacts to surface and groundwater resources. As a result, impacts are predicted to be minor at the most.

Releases to the marine environment are confined to the possible discharge of loading line hydrotest solution during commissioning. As these impacts relate to the marine environment, this is discussed in Section 13.

12.4.2.2 Mitigation

All necessary precautions to prevent the pollution of inland surface and groundwater resources will be taken. In order to achieve this, specific method statements/procedures for the control of relevant construction activities will be developed by the Contractor, and approved by BOTAŞ, the Ministry of Environment and the Department of State Hydraulic Works as appropriate.

Key environmental requirements include the following:

- measures for the control of refuelling and vehicle washing activities;
- measures for the control of vehicle movement in the vicinity of irrigation channels, field drains and ephemeral watercourses;
- measures for the control of runoff from the construction area and other areas;
- measures for the safe disposal of waste waters and other liquid effluents;

- measures for emergency response in the event of a pollution incident.

The above measures are addressed in detail in the Environmental Management and Monitoring Plan (EMMP) (Appendix C1), together with the Waste Management Plan (WMP), Pollution Prevention Plan (PPP), and Traffic Management Plan (TMP) (Appendices C3, C4 and C5). These management plans represent the technical basis for the development and maintenance of key environmental management systems and procedures during the implementation of the scheme and will evolve and adapt as the implementation of the BTC Marine Terminal progresses.

The measures for the safe storage and handling of all fuels, lubricant oils, chemicals and liquid wastes will also apply to the protection of groundwater resources.

During loading and line construction, every precaution will be taken to prevent silting, erosion and pollution of ephemeral watercourses, irrigation channels and drainage ditches. If, notwithstanding the following precautions, such as silting, erosion or pollution does take place during the construction phase, emergency procedures in accordance with the PPP will be put in place and immediate action taken to minimise the effect on the watercourse and to prevent any reoccurrence of the event.

All construction wastewaters arising (eg run-off from potentially contaminated areas, from vehicle wash areas, canteens, sanitary facilities) will be treated to the standards described in Appendix D. Approvals for any discharge from the sites will be obtained from the Authorities. Provisions, such as pre-discharge monitoring, settlement lagoons, grass plots or sediment filter systems will be used to ensure that pollution does not occur. Since final discharge locations have not yet been identified, further investigations will be carried out to assess the most appropriate option or options for treated discharges, including reuse for irrigating land on the BOTAŞ site and discharge to soakaway.

12.4.3 Operational impacts and mitigation

12.4.3.1 Surface water

Aqueous discharge from the operational marine terminal are summarised in Table 12.4. These apply to normal operations; ie they do not include storm events when run-off volume flows will clearly increase and be highly variable.

Table 12.4 Approximate Operational Discharges from the BTC Marine Terminal

Discharges	Primary holding pond	Treated wastewater	Irrigation and/or soakaway	24 m^3 per day
	General facilities	Treated wastewater	Irrigation and/or soakaway	24 m^3 per day
	Housing compound	Treated wastewater	Irrigation and/or soakaway	38 m^3 per day
	Jetty	Treated wastewater	Irrigation and/or soakaway	1.5 m^3 per day
	Guardhouse	Treated wastewater	Irrigation and/or soakaway	1.5 m^3 per day
	Tank farm	Treated wastewater	Irrigation and/or soakaway	2 m^3 per day

A central wastewater treatment plant will be provided to process all wastewater from the terminal facilities as described in Section 9. The wastewater treatment plant will comprise a primary holding pond, biological wastewater treatment plant and storm water pond. Following treatment, effluent that meets the standards required by Turkish legislation and the World Bank (see Appendix D) will be discharged at a controlled flow rate to the environment.

Drainage from contaminated areas (vehicle washing, machinery etc) will be connected to the oily water system. This will gather potentially contaminated water streams that will be then routed via an oil separation unit to the primary withholding pond and then to the stormwater pond. Oily water sources at the marine terminal will include the following:

- storage tank bunds (tank roof runoff, tank drain, storm water in the bund area etc);
- process area bunds at the receiving station and the relief tank bund;
- fiscal metering station bund.

All marine terminal waste streams will therefore discharge to the environment via the stormwater pond, at a controlled flow rate. At present the preferred option is to use the treated wastewater for irrigation on the terminal site. The water will be treated to a quality that allows this. However, should this prove infeasible then discharge will be to soakaway (see below). There will be no discharge to surface waters and therefore no impact to them.

12.4.3.2 Groundwater

The presence of the proposed BTC terminal facilities will result in an increase in hardstanding. This will result in greater runoff from the hardstanding to the surrounding areas altering the drainage regime locally. In addition, the tanks will be bunded with an impermeable bentonite clay, also resulting in similar impacts to those described above. These alterations to local hydrology could cause impacts to groundwater, however as there are no significant groundwater resources at the site, predicted impacts to groundwater are minor at most.

Operational discharges have the potential to cause impacts to groundwater quality. There are two options for the disposal of treated wastewater as follows:

- irrigation of orchards on the terminal site;
- soakaway.

The preferred disposal option is the re-use of treated wastewater as irrigation water, however provision is also being made for soak away. The discharge location would be situated approximately 1.5km from the unconfined aquifer to the west and south west and approximately 500m from the nearest on-site accommodation.

The feasibility of discharge to soakaway at the terminal site is still to be examined. Ensuring the discharge has no more than a minor impact to water resources will require a two-phased investigation:

- In the first instance the capacity of the ground to physically accommodate the water flows will be investigated. Trial pits will be excavated and percolation tests will be undertaken of the surface strata at the site to establish their characteristics (porous versus fissured) in terms of capacity to accommodate the waste flows.

- Secondly, simple dispersion modelling (using analytical solutions similar to those recommended for the RBCA of contaminated sites) and risk assessment will be undertaken to establish potential impacts to the nearest groundwater resource. This

may feed back into further ground investigations, in the event for example that a decision to opt for fissured flow then raises an unacceptable level of risk.

In the event that the discharge is to either soakaway or irrigation, impacts to groundwater will be minor on the basis that (a) the wastewater is treated to the standards required by Turkish legislation and World Bank (described in Appendix D) and (b) there is no valuable groundwater resource put at risk.

12.4.4 Abstraction of water

Means of supplying the construction camp and operational terminal are being investigated since current supplies used in the BOTAŞ Marine Terminal will need to be supplemented. A one-off large volume supply of water (approximately 150,000m^3) will also be required to test the tanks. The tanks will be tested in series, reducing the volumetric requirement.

The main option under investigation is abstraction of groundwater from a location 15km east of the terminal, near to Burnaz Springs. Pumping tests and sampling will be undertaken to establish:

- whether the water is of acceptable quality;
- whether the water can be sustainably abstracted at the rate required without impacts to other users.

On the basis that feasibility is established according to the above criteria then approval from DSI will be required.

The loading lines will be tested using seawater; resource use impacts for this operation will therefore be minor.

12.5 BIOLOGICAL ENVIRONMENT

12.5.1 Introduction

This section identifies potential impacts to the biological environment as a result of construction and operation of the proposed BTC Marine Terminal. Impacts to ecology have been identified when an activity is predicted to result in a change to the baseline situation. The significance of an impact has been determined using the impact significance criteria set out in Section 3 of this report. The significance of any potential impact on ecology will ultimately depend on the status of the habitat or species and the predicted change as a result of an activity. The scale of an impact is generally subjective and often difficult to quantify. Mitigation measures have been identified and details are presented in this section.

Impacts to coastal and marine habitats and species are dealt with in Section 13.6.

12.5.2 Construction impacts and mitigation

The construction of the BTC terminal facilities will result in disturbance to the following areas of habitat, which are in the possession of BOTAŞ:

- approximately 32ha of maquis scrubland associated with the construction of the tank farm;
- approximately 0.6ha of maquis scrubland associated with the construction of the loading lines;

- approximately 2.4ha of agricultural land associated with the construction of the loading lines;
- approximately 3.0ha of woodland associated with the construction of the loading lines;
- approximately 1.2ha of gardens and orchards associated with the construction of the loading lines.

Only the landtake associated with the tank farm will be permanent, long term impacts associated with habitat loss are discussed in the Section 12.5.3. Once the loading lines have been installed, the habitats will be reinstated, thus disturbance impacts will be short term in nature.

Approximately 83% of the disturbed area is associated with Anatolian maquis scrubland, whose faunal assemblage includes eight Turkish Red Data Book species (see Section 10.7.2). Although these species have not been assigned categories by the IUCN, they have been identified as meeting the criteria for the IUCN 2000 Red List and as such could be assigned categories in the future (Yusuf Gemici, *pers. comm.*). Pre-construction botanical surveys will be undertaken and if species of conservation value are found, strategies to minimise their loss or disturbance will be developed. This will include, as appropriate:

- transplanting;
- fencing off;
- avoiding use of such areas for construction laydown, temporary soil storage etc.

Impacts to maquis habitat within the overall BOTAŞ boundary are predicted to be moderate, however given that maquis is a widespread habitat in the wider area, overall impacts are considered to be locally minor. Some pine trees may be lost due to the positioning of one of the tanks. This is not ecologically significant and has been addressed above in a landscape value context.

Bird surveys carried out during spring/summer 2001 and Autumn 2001 identified a number of internationally and nationally protected bird species at or near the site. The birds observed are known not to be breeding in the area. The majority of the birds observed were raptors and were observed to be wide ranging, feeding both in the Study Area and on the surrounding agricultural land. Several dove species probably range between the terminal site and surrounding woodland. Disturbance to birds is unlikely to cause significant effects due to the fact that the birds are not breeding in the area and are observed to be wide ranging and highly mobile. Impacts to birds during construction are therefore predicted to be minor.

Reptile surveys were also carried out at the terminal site; these identified a number of internationally and nationally important species. Disturbance to these species will depend on the relative mobility of the species. As the mobility of some reptile species is limited, impacts are likely to range between minor and moderate, but are not considered significant in the long term (ie once the tank farm and loading lines have been installed).

Mammals of note were recorded during the Phase II habitat survey. As well as large numbers of small rodents, the Brown Hare (*Lepus capensis*) and bats were also observed. The scope for impacts to mammals is low due to the following:

- the habitats with which these species are associated (maquis and woodland) are widespread in the wider area;
- these species are relatively mobile and wide ranging.

Since a number of protected bat species are present in Turkey, specialist pre-construction surveys will be undertaken to ensure that bat roosts, if present on the site can be either protected or removed without harm to the bats themselves (see also Annex A of the Environmental Management and Monitoring Plan in Appendix C1).

The goitred gazelle (*Gazella subgutturosa*) has recently been reintroduced at the existing BOTAŞ terminal site. As this species is confined in pens on the existing BOTAŞ facilities in an area that will not be required for temporary construction, no impacts are anticipated.

As well as traversing maquis habitat, the loading lines will also traverse agricultural land, woodland and gardens/orchards as mentioned above. It should be noted that the site avoids the more sensitive and valuable dune habitants between the proposed and existing jetty alignments. The EIA scoping exercise did not identify the need for detailed ecological surveys of the loading line route to be undertaken. However, bird and reptile species are known to be similar to those identified during the tank farm surveys, as the species are wide ranging and have been observed to use a range of habitats in the area. The key potential impacts are disturbance or loss of rare or otherwise noteworthy species during trenching activities.

Pre-installation surveys by appropriate specialists will be carried out prior to trenching, and any sensitive species noted. Where appropriate, mitigating measures will be taken, including the following:

- working areas (eg loading line laydown areas etc) will be sited to avoid ecological sensitivities;
- reinstatement and/or transplantation plans will be developed for any notable species identified in the loading line working width;
- any seasonal sensitivities (eg breeding birds) will be noted, and works scheduled appropriately;
- waste will be disposed of according to guidance outlined in the Waste Management Plan (Appendix C3);
- dust will be controlled using dust suppression methods outlined in the Pollution Prevention Plan (Appendix C4);
- mitigation measures outlined in the Pollution Prevention Plan will be adopted to minimise impacts to aquatic habitats.

By carrying out the surveys and applying the mitigation measures outlined above, impacts are anticipated to be minor to moderate.

12.5.3 Operational impacts and mitigation

Operation of the BTC Marine Terminal will result in long term habitat loss wherever there are permanent structures and hardstanding surfaces and the generation of operational noise and light, which have the potential to cause impacts to terrestrial ecology.

Approximately 32ha of maquis scrubland will be permanently lost as a result of the presence of the tank farm. This habitat is widely distributed in the vicinity of the proposed terminal and impacts to faunal communities are predicted to be minor. The bird, reptile and mammal species observed during ecological surveys of the site already co-exist with the existing BOTAŞ terminal facility. The pre-existing conditions greatly reduce the scope for impact.

Observations at the existing facilities show that the terrestrial ecology of the site is not significantly adversely impacted by terminal operations. For example, birds and bats, which may be considered sensitive to disturbance, are numerous and frequently observed. Clearly these species must be fairly acclimatised to the levels of existing human activity, movement noise and night lighting. Impacts are therefore anticipated to be minor during operation.

No permanent habitat loss is associated with the loading lines as the trenches will be reinstated following installation. Best practice reinstatement methods will be followed (Appendix C2).

Some planting is planned for landscaping purposes. This will utilise only species that are native to the area and, based on observations of existing conditions, are thriving in the local climatic and soil conditions.

The long term impacts are considered to be minor.

12.6 AIR QUALITY

12.6.1 Introduction

This section identifies the potential impacts to air quality as a result of construction and operation of the BTC Marine Terminal. Impacts to air quality fall into two categories, fugitive emissions and point source emissions. An impact has been identified when an activity is predicted to result in a change to the baseline situation. The significance of an impact has been determined using the impact significance criteria set out in Section 3 of this report. The significance criteria are largely based on World Bank and Turkish standards, however EU standards and World Health organisation standards have also been referred to for each category of impact. Where no standards are available, professional judgement has been used.

Mitigation measures have been identified and details are presented in this section.

12.6.2 Construction impacts

12.6.2.1 Dust emissions

Dust generated during construction can be significant locally. The following activities have the potential to result in the generation of dust during construction:

- earthmoving operations on site (excavation and removal of surface soils);
- earthworks engineering;
- site stripping;
- wind blow;
- movements of vehicles and trucks for the import of construction materials, for the export of excavated soil, for the transport of the workers and the delivery of site equipment.

Dust impacts, even without mitigation, would not be experienced at the nearest community, which is in excess of 500m from the site boundary. Some agricultural landuses in closer proximity could potentially be exposed to minor or moderate short term impacts depending how close they are to working areas. Standard dust mitigation measures (outlined below and described in the EMMP) will be employed when working within 250m of sensitive land uses, subject to soil moisture and weather conditions.

12.6.2.2 Other emissions

The movements of vehicles will also result in the emission of airborne pollutants, from their exhausts. The quantity of such emissions will depend on the number of the vehicles concerned, vehicle type, their state of maintenance and the volume of traffic. The main pollutants of concern from road traffic are PM_x and NO_x. EC Air quality standards for these pollutants can be exceeded when traffic flows are in the order of those experienced during an urban rush hour. Traffic to and from the marine terminal will be a small fraction of such levels and impacts to air quality will therefore be minor.

12.6.2.3 Mitigation measures during construction

A series of measures will be used as required to control dust and other emissions to air including, but not be limited to, the following:

- measures for the storage and handling of spoil, sub-soils and top-soils;
- measures for the control of vehicle movements on site;
- measures for the control of site operations (including trash burning);
- measures for the avoidance of nuisance from exhaust emissions.

These are described in more detail in the EMMP and PPP.

12.6.3 Operational impacts

12.6.3.1 Introduction

Operational emissions to atmosphere are important both in the context of:

- the impacts and mitigation for the BTC Marine Terminal itself;
- the impacts it will have in combination with other existing and planned industries on the northern coast of the Gulf of Iskendurun.

The latter issues are also addressed in Section 16 (Cumulative Impacts). The complete operational air quality assessment and dispersion modelling results are presented in Appendix B2 and are summarised in the following sections.

The underlying approach to the air quality assessment was:

- to identify and quantify all emission sources, including existing ones, the BTC Marine Terminal and proposed future industry;
- to use atmospheric dispersion modelling to predict ground level concentrations of atmospheric pollutants of concern for all sources combined:
- to establish the BTC Marine Terminal contributions to ground level concentrations;
- to compare predicted concentrations with applicable air quality standards and evaluate the significance of the BTC Marine Terminal's impacts on air quality.

Mitigation measures are not addressed discretely, but where mitigation and design considerations have been made in an air quality context these are highlighted below.

12.6.3.2 Pollutant sources

The main pollutant sources considered in the assessment are summarised in Box 12.1.

Box 12.1 Summary of BTC Marine Terminal and Other Main Pollutant Sources

BTC Marine Terminal

- Storage emissions: will occur as fugitive releases from the seven external floating roof tanks. These were selected in favour of fixed roof tanks as having lower emissions but minor VOC releases will result comprising 25te per annum, approximately 12kg of which will be benzene.
- Tanker loading emissions: approximately 59,000te per annum VOCs will be generated during tanker loading and will be collected and piped to an enclosed ground flare (EGF) with a VOC combustion efficiency of approximately 99.5%. The EGF was selected as the optimum option in terms of local air quality impacts for the reasons explained in Section 2. Its operation will annually introduce approximately: 215te VOC; 295kg benzene; 36te No_x; 387te SO_2; and 152,450te CO_2.

Existing BOTAŞ Marine Terminal

- Tanker loading emissions: the existing terminal has no VOC emission controls and emits approximately 3,000te VOC, including 3te benzene, per annum, during loading operations at the end of the jetty.
- Storage emissions: these occur from the tank farms serving the Iraq and Kirikkale pipelines at an approximate rate of 74te per annum, including 115kg benzene.

Existing Industry

- The Toros Gubre Fertiliser Facility (5km to the northeast) emits approximately 643te NO_x per annum.

Proposed Industry

- The Sugozu coal-fired Power Plant, due to commence operation in 2003, will emit approximately 10,600te NO_x and 6,500te SO_2 per annum.

Other Sources

- Other sources include local road traffic and shipping. These cannot be reliably quantified and were not included in the assessment, but can be regarded as having minor influences in comparison with the major industrial sources.

12.6.3.3 Assessment methodology

VOC fugitive emission rates from the storage tanks were characterised using the Tanks-4 emission software developed by the US Environmental Protection Agency (USEPA). Emissions from the flare were estimated using mass balance and engineering calculations. Emissions from the other sources (existing BOTAŞ Jetty, Toros Gubre Fertiliser Facility and Sugozu Power Plant) were estimated using USEPA emission factors.

Ground level pollutant concentrations were predicted using the USEPA's ISCST3 air quality dispersion model, with meteorological input data from the nearby Yumurtalik meteorological stations.

Full details of the approach are given in Appendix B2, along with the results. The scenarios modelled are summarised in Box 12.2.

Box 12.2 Pollutants and Emission Scenarios Modelled

- Annual Average VOC concentrations due to combined emissions;
- Percent concentration of BTC emissions to annual average VOC concentrations;
- Predicted 95th percentile VOC concentrations due to combined emissions;
- Contribution of BTC emissions to 99th percentile VOC emissions;
- Predicted annual average benzene concentrations due to combined emissions;
- Predicted annual average NO_x concentrations due to combined emissions;
- Predicted 95th percentile NO_x concentrations due to combined emissions;
- Predicted 99th percentile NO_x concentrations due to combined emissions;
- Contribution of BTC emissions to 99th percentile NO_x concentrations;
- Predicted annual average SO_2 concentrations due to combined emissions;
- Predicted 95th percentile SO_2 concentrations due to combined emissions;
- Predicted 99th percentile SO_2 concentrations due to combined emissions

Of the scenarios identified in Box 12.2, the results of the predicted annual average NO_x and SO_2 concentrations due to combined emissions are presented as Figure 12.2 and Figure 12.3 respectively. Graphic outputs of the other scenarios modelled are presented in Appendix B2.

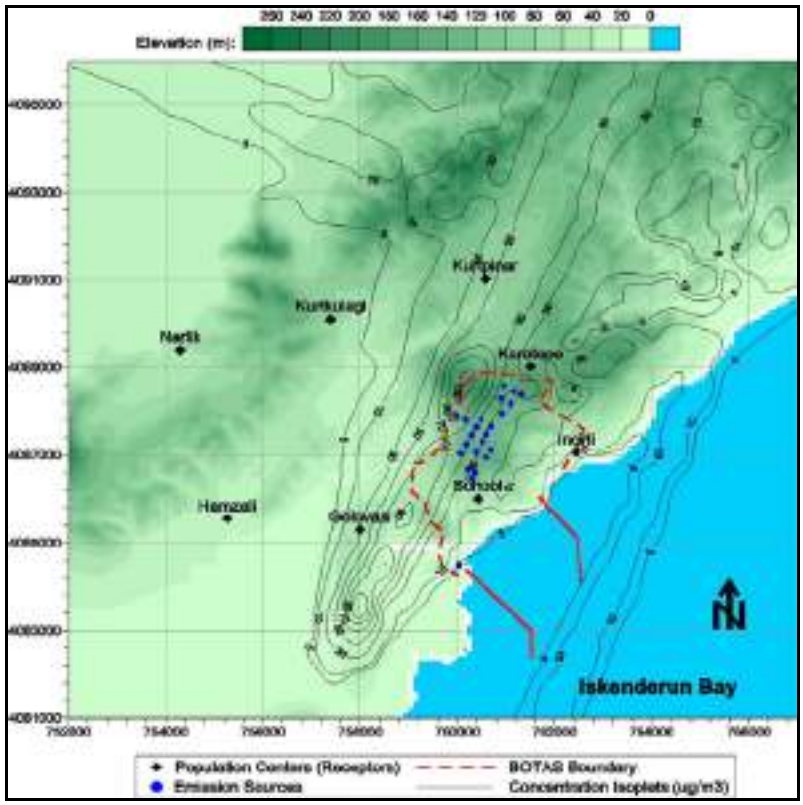

Figure 12.2 Predicted Annual Average NO_x Concentrations Due to Combined Emissions

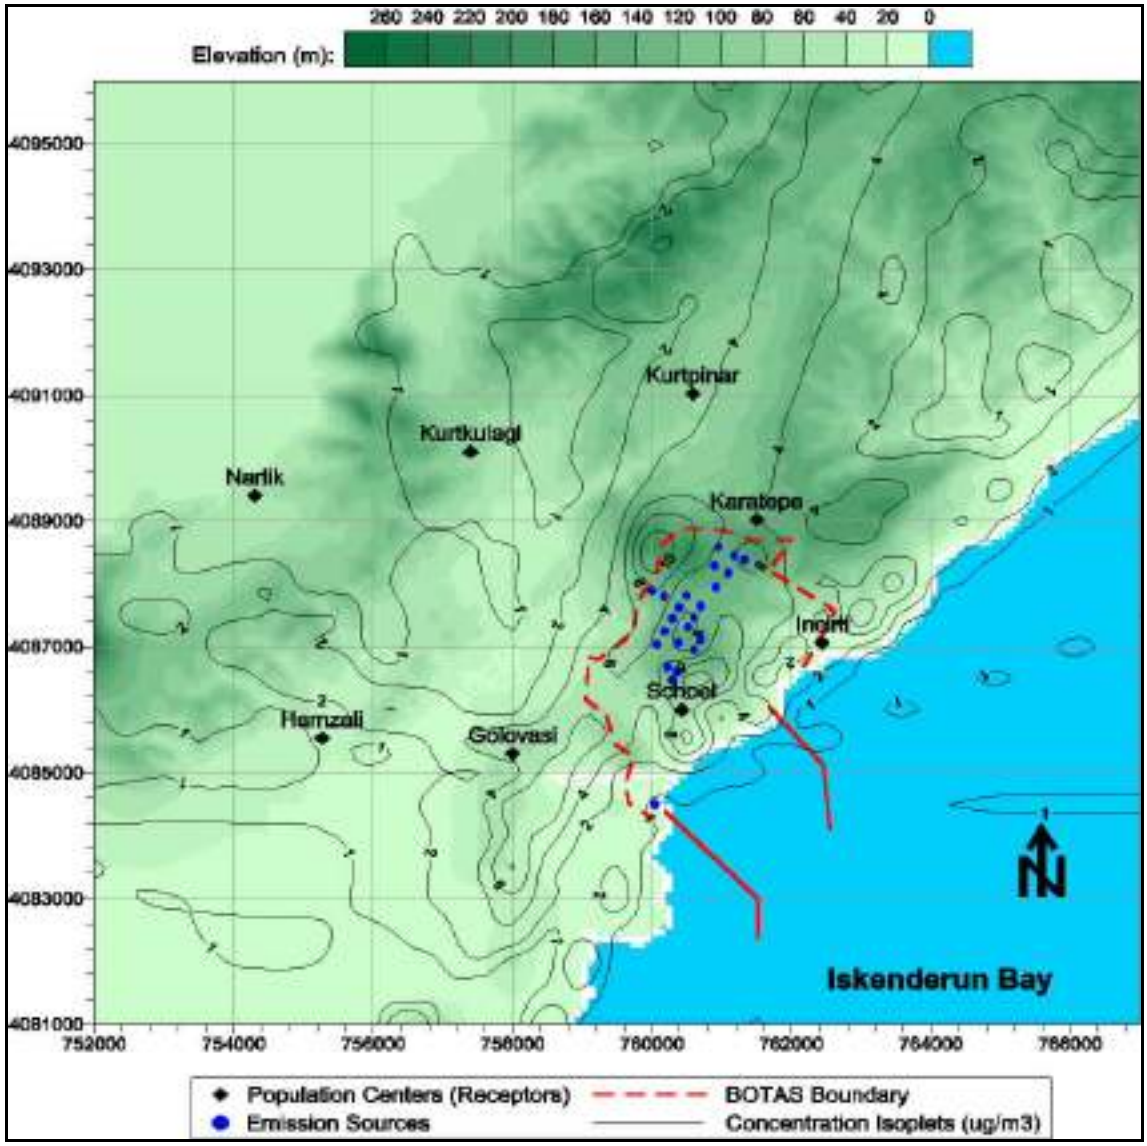

Figure 12.3 Predicted Annual Average SO_2 Concentrations Due to Combined Emissions

12.6.3.4 Summary and evaluations of air quality impacts

The findings of the air quality modelling study can be summarized as follows:

- The proposed BTC emissions will constitute approximately 7% of the total VOC emissions in the project area. The existing BOTAŞ crude oil loading facility is the largest VOC emitter comprising 88% of the total emissions.

- There are occasional existing short-term (hourly) VOC-related air pollution episodes due to the existing BOTAŞ facilities. Turkish hourly and 95th percentile VOC standards are exceeded during certain meteorological events (eg low wind speed and stable atmospheric conditions) in a strip of land west of the BOTAŞ facilities and on the BOTAŞ facility shoreline. The main cause of these exceedances is the existing BOTAŞ crude oil loading (jetty) operations which have uncontrolled emissions released under poor dispersion conditions (ie low release elevation).

- The contribution of the BTC emissions to the short-term VOC atmospheric pollution episodes will be minimal, if not zero. The contribution of the BTC Marine Terminal to hourly maximum concentrations will be less than 1μg/m^3. During the predicted episodes, most of the BTC sources will be located downwind from the areas experiencing the air pollution, and therefore, will not have any influence on them.

- The predicted annual average benzene concentrations are at safe levels, which are approximately three orders of magnitude lower than the EU standard and the WHO guideline.

- The proposed BTC emissions will constitute 0.5% of the total NO_x emissions in the project area. The Sugozu Power Plant, which is currently under construction, will be the largest NO_x emitter (93.8%) in the project area.

- The predicted annual and 95th percentile NO_x concentrations are in compliance with the ambient air quality standards. However, EU hourly standards are exceeded occasionally on the hills immediately north of the existing BOTAŞ facility due to the existing industries. The contribution of the BTC emission to these hourly pollution episodes will be less than 0.5μg/m^3.

- The proposed BTC emissions will constitute 10% of the total SO_2 emissions in the project area. The predicted annual and short-term SO_2 concentrations are in compliance with the ambient air quality standards.

Based on the findings of the air quality modelling study, it can be stated that the impacts of the proposed BTC complex on the local air quality will be minor, localised and within established national and international standards/guidelines. Cumulative impacts and impact interactions are discussed in Section 16.

12.7 NOISE

12.7.1 Introduction

The construction and operation of the proposed onshore facilities will generate noise levels that could potentially impact nearby noise sensitive receivers. This section assesses the potential for such impacts by considering the proximity and nature of the surrounding land uses and the likely levels of noise emitted during construction and operation of the onshore facilities. The significance of any impact has been assessed using the significance criteria outlined in Section 3.

Mitigation measures have also been identified and are presented in the following sections.

12.7.2 Construction impacts and mitigation

12.7.2.1 Sources of noise

Construction of the BTC Marine Terminal will encompass a variety of activities that will potentially generate noise as follows:

- General civil works involved in constructing the tanks, general facilities and accommodation blocks will include the requirement for earth moving machinery, diesel generators, air compressors etc. In addition, blasting and piling may be required.

- Trenching and laying the loading line will involve specialist heavy equipment, including side boom cranes, as well as generators for welding equipment.

All construction activities will have associated noise from traffic relating to the delivery of materials and workforce.

12.7.2.2 Mitigation

The mitigation measures described in the following sections will be employed during construction in the vicinity of noise-sensitive receptors, eg residential dwellings to ensure that adverse noise impacts are avoided.

Hours of Work

Construction working hours will be agreed with the relevant authorities and BOTAŞ prior to mobilisation, with a view to minimising the disturbance to local residents, both in the existing BOTAŞ facilities and offsite, where impacts might be experienced.

Limited construction activities may have to continue on a 24-hour basis. Approval of the relevant authorities and BOTAŞ will be obtained prior to commencement of any night-time works. Night-time working will be kept to a minimum and will be discussed and agreed in advance with BOTAŞ and the relevant authorities, including Muhtars as part of the Community Relations Strategy, discussed in Section 12.10.2.

Construction Plant

- Noise levels expected from the agreed method of working and chosen plant and equipment will be identified and specific measures appropriate to the selected plant will be implemented to minimise the impact of noise.

- All plant will be adequately maintained to minimise noise emissions and only inherently quiet plant will be selected for use on site. Where plant has been designed to operate with engine covers to reduce noise, these will be used and remain closed at all times whilst the plant is in operation. All items of plant operating on the site in intermittent use will be shut down in the intervening periods between uses. Routine checks will be undertaken to identify equipment that is emitting unacceptably high noise levels or particular tonal characteristics, which, through appropriate repair or general servicing, could be reduced. All equipment on site will be properly maintained to prevent unnecessary noise emissions.

- For types of plant and equipment whose noise emissions are governed by the Turkish Regulation on Noise Control or World Bank standards, only plants bearing an appropriate conformity mark will be brought to and used on the site.

- Any item of plant or equipment found to be emitting excessive noise levels due to a faulty silencer, broken or ill-fitting engine covers or other reasons, will immediately be taken out of service for repair or replacement as required to ensure it operates within its designed noise envelope.

- Noisy plants will be located as far from inhabited buildings as possible. Advantage will be taken of natural screening (eg trees etc) where practical to further attenuate noise. Where practical, the stockpiling of site materials, soil or spoil will be located where it can provide some additional screening provided that any plant associated

with this does not in itself generate nuisance. Noise barriers will additionally be used where significant noise impacts are anticipated. Plants known to emit directional noise will be orientated so that the noise is directed away from sensitive receptors.

- Site personnel will be trained in the proper use and maintenance of tools and equipment, and the positioning of machinery on site to reduce noise emissions to neighbouring settlements.

Piling and Blasting

- Piling activities will be subject to rigid safety, noise and vibration control procedures including procedures to ensure adequate warning is given to anyone who may potentially be affected.

- Blasting activities (if any are required at the BTC Marine Terminal site) will be subject to rigid safety and noise and vibration control procedures including procedures to ensure adequate warning is given to anyone who may potentially be affected.

It is considered that the above measures provide adequate protection from noise and vibration, as piling and blasting activities will only take place during the daytime.

Noise limits from the Turkish Noise Control Regulations (NCR) for noise levels to be achieved at receptors during construction are presented in Appendix D. The distances at which the noise criteria are met for each category of construction activity is also provided, in Section 6.

The closest noise sensitive receptors to the BTC Marine Terminal site are as follows:

- fishermen's settlement (south) 700m;
- housing compounds 900m;
- BOTAŞ lodges 1000m.

As the critical distances for all categories of construction activity are well within the distances for the nearest noise sensitive receptors, impacts to these receptors during construction are anticipated to be minor.

The potential impacts may be greater at some specific locations due to factors such as the proximity of works or the necessity of night-time activities and specific noise controls may be necessary at these locations. Specific mitigation measures, such as the use of noise barriers will be identified and implemented at the required locations prior to the commencement of noisy activities.

Traffic Noise

Construction traffic, especially heavy vehicles, has no potential to cause noise impacts, since in accessing the site it will use roads that pass through or close to residential areas. There will be existing traffic and noise but the marine terminal construction may substantially add to it. In the absence of fixed routes for construction traffic into and out of the site, it is not possible to state which roads and settlements will be most vulnerable. However, impacts will be mitigated to the maximum extent through implementation of the Traffic Management Plan (see Appendix C5), including such measures as:

- Sensitive routing of heavy loads;

- Observation of vehicle speed limits;
- Vehicle maintenance;
- Avoidance of passage through and near to settled areas during night time hours.

These are other measures will ensure that traffic noise impacts are predominantly minor, or at most moderate as locations where traffic flows are greatest.

12.7.3 Operational impacts and mitigation

12.7.3.1 Main noise sources

The main noise source from the operational BTC Marine Terminal will be the transfer pumps to be located in the tank farm and flare system (flare and blower) to be installed onshore near to the jetty.

Because of the distance of receptors such as housing compounds of the new terminal and nearby settlements from the noise source, it is anticipated that operational noise impacts from the pumps will be minor. This is a reasonable prediction since loading operations at the present facility do not result in noticeable noise impacts to the aforementioned receptors. Accordingly, the assessment of operational noise is focused on the flare system.

12.7.3.2 The flare system

Flares are generally categorized in two ways:

- by the height of the flare tip (ie ground or elevated);
- by the method of enhancing mixing at the flare tip (ie steam-assisted, air-assisted, pressure-assisted, or non-assisted).

An enclosed flare's burner heads are inside a shell that is internally insulated. The shell reduces noise, luminosity, and heat radiation and provides wind protection. Enclosed, or ground-based flares are generally used instead of elevated flares for aesthetic or safety reasons (EPA, Air Pollution Technology Fact Sheet). Enclosed flare and elevated flare options were compared in order to determine the one to be proposed for the BTC Marine Terminal in terms of both noise and air pollution. As a result, the proposed BTC Marine Terminal flare is an enclosed ground flare. Its enclosure will have a height of about 25m. In addition, the diameter is planned as 10m.

Combustion noise is created by the conversion of some of the thermal energy available in the fuel gas to acoustic power. As illustrated in Figure 12.4, the frequency of this energy is typically in the audible range, from 32 Hz to 10000Hz, exhibiting a peak between 250 and 500 Hz) (www.natcogroup.com).

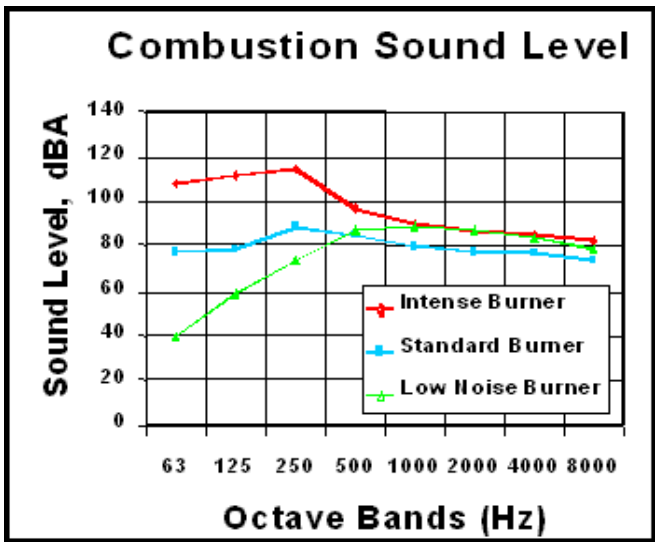

Figure 12.4 Combustion Sound Level and Octave Bands

The flare system proposed for the BTC Marine Terminal will be equipped with a silencer to reduce noise.

According to manufacturers information, a sound power level (PWL) of approximately 110dB(A) is expected to be generated by a large EGF as mentioned above at a waste gas flow rate of 20,000 m³/h.

Figure 12.5 provides information on the location of the noise sensitive receptors in the vicinity of the proposed BTC Marine Terminal and presents the results of the noise modelling study. This study considered actual site-specific conditions at the BTC Marine Terminal such as topography, meteorology and vegetation cover, all of which provide a level of noise attenuation. Noise contours predicted from this study indicate that noise levels at the receptors are much lower than the limit values stipulated in the World Bank guidelines (ie 55 dB(A) daytime and 45 dB(A) night-time, the latter being the most critical). According to the significance criteria in Section 3, this is a minor impact.

12.7.3.3 Air Blower

When blowers are enclosed with a sound attenuating enclosure, the generated noise decreases to less than 70 dB(A) at 21 feet (ie 6.5m) (www.polarpowerinc.com). Using the equation below, it is calculated that at 100-150 m away from the source, the noise level will be less than the World Bank limit values of 55 dB(A) daytime and 45 dB(A) night time. Impacts at all residential receptors are therefore predicted to be minor.

$$SPL_2 = SPL_1 - 20 \times \log \frac{D_2}{D_1}$$

where,
SPL_1: Sound pressure level (reference value used for calculation) at distance D_1 (reference distance)
SPL_2: Sound pressure level (calculated value) at distance D_2

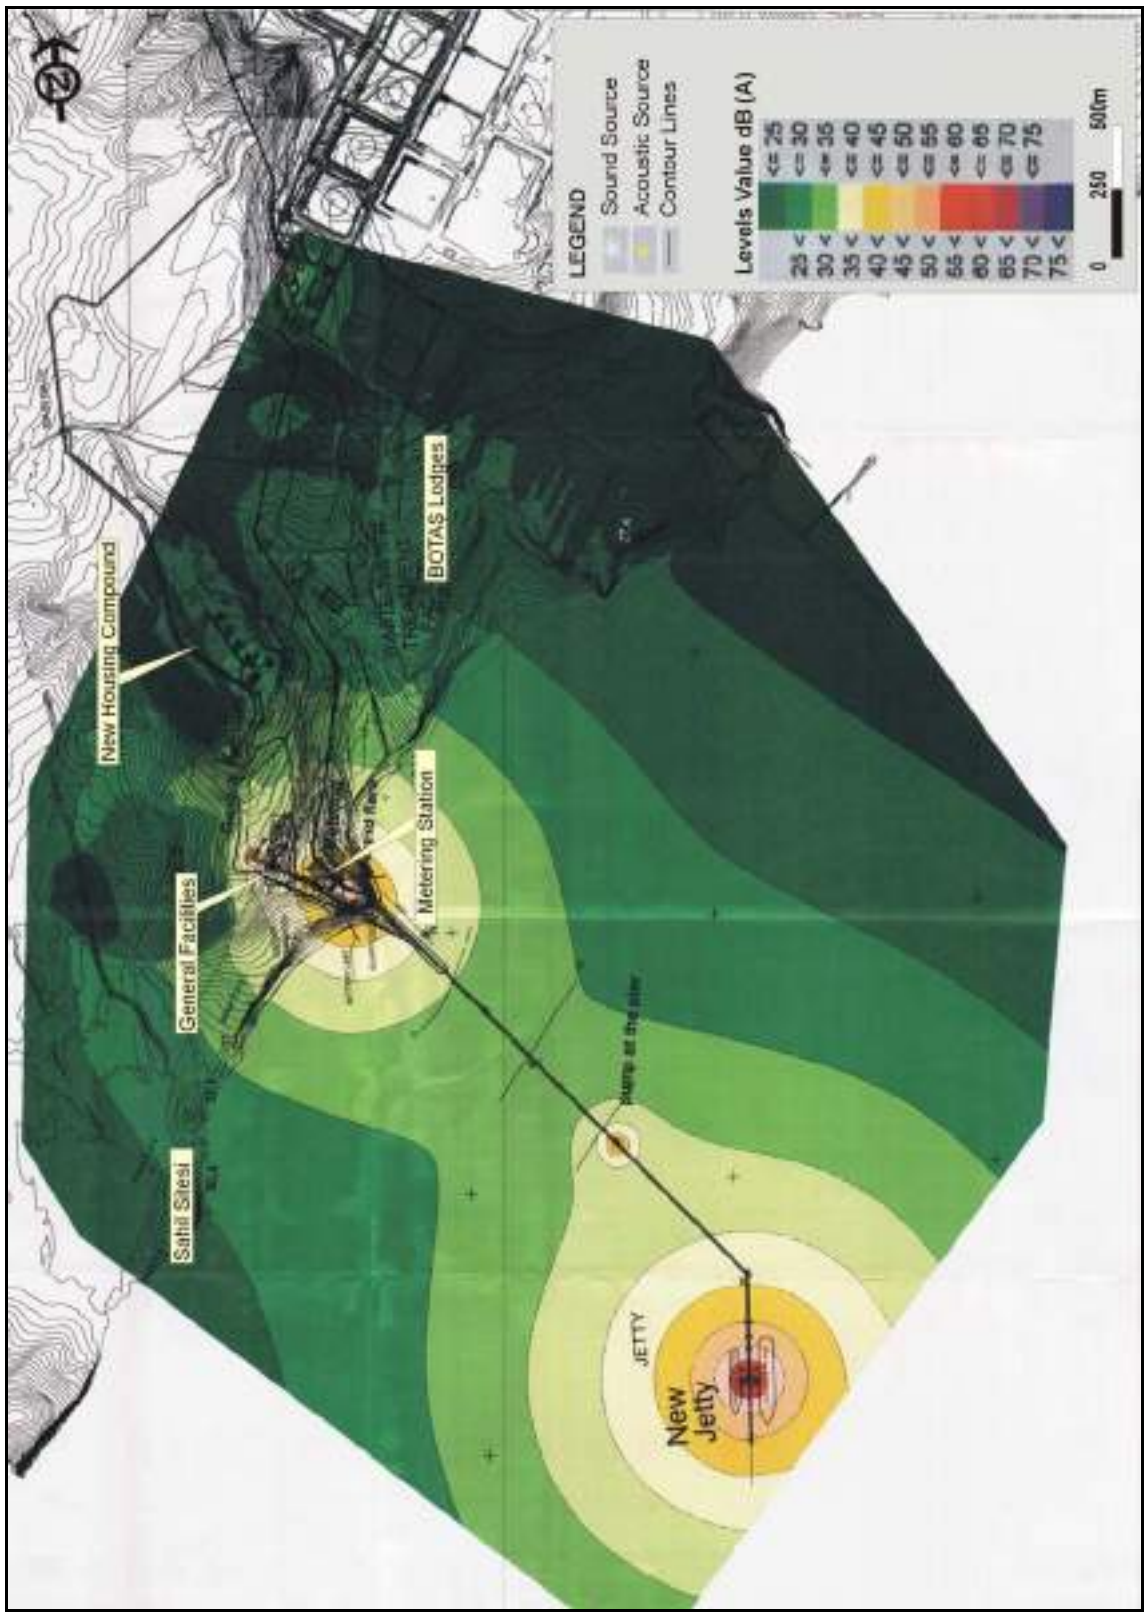

Figure 12.5 Noise Sensitive Receptors in the Vicinity of the BTC Marine Terminal

Loading lines

Pigging and scraping operations will create noise along the loading lines at different times of the year. However, this noise source will be transient and temporary. Low levels of noise are expected to occur during launching PIGs and scrapers. Furthermore, as the loading lines will be buried until they reach the jetty, noise impacts to nearby noise receivers are anticipated to be minor at most.

12.7.3.4 Mitigation

Additional mitigation has been developed to minimise operational noise impacts, including the following:

- equipment will be furnished with noise reduction devices to meet regulations where required;
- connecting pipes will be acoustically lagged where necessary;
- air intakes at furnace burners will be equipped with silencers where necessary;
- large motors will be specified to comply with noise regulations;
- control valves and piping will be designed to comply with noise regulations, with or without insulation.

12.8 TRAFFIC AND TRANSPORT

12.8.1 Introduction

The construction and operation of the BTC Marine Terminal and associated infrastructure may lead to impacts on existing road users and other sensitive receptors. This section discusses the assessment of such impacts and identifies measures to mitigate them.

The assessment was undertaken with reference to the requirements of the World Bank's Environmental Assessment Sourcebook [Ref 1] and UK guidance on Transport Assessments and according to the criteria in Section 3.

The main potential impacts associated with the terminal may include:

- increases in traffic flows on the road network and their potential for delays and congestion;
- conflicts between motorised and non-motorised forms of transport (eg delays to pedestrians and cyclists);
- visual intrusion, increased roadside litter and traffic-related noise and emissions;
- the loss of vegetative cover brought about by the construction of new roads;
- water pollution from spills or accumulated contaminants on road surfaces and potential modifications to natural drainage patterns brought about by construction of new roads;
- traffic accidents, which may result in death, injury or environmental damage.

Traffic also leads potentially to noise and air quality impacts. These impacts are addressed in Sections 12.7 and 12.6 respectively.

12.8.2 Potential construction impacts

Equipment, material and waste will have to be transported to/from the site. Personnel movements will also contribute to increased traffic volumes during the construction phase. Until the Construction Contractor develops a detailed programme, the exact volumes of traffic and how they will vary through the construction phase cannot be quantified.

Some of the items that need to be transported to the site will constitute abnormal loads, eg the steel piles for the jetty, the steel plate for tanks, turbines, compressors for firewater pumps and the oil loading arms for the jetty. These are likely to result in significant effects on local roads.

Other potential impacts include:

- increases in traffic flows on the road network and their potential for delays and congestion to local agricultural vehicles, especially during harvest time;
- impacts on the existing residents of the on-site BOTAŞ property.

Generic measures to mitigate these and other potential impacts are summarised below and discussed in detail in the Traffic Management Plan in Appendix C5.

12.8.3 Generic mitigation measures

A number of mitigation measures will be incorporated to reduce the temporary traffic-related impacts of constructing the terminal. These are discussed below.

12.8.3.1 Consultation/liaison

The relevant authorities will be consulted to agree on specific routes for use by construction traffic to avoid to the maximum extent possible any sensitive residential areas and unsuitable parts of the road network. In addition, advance warning will be given of construction works, including details of any proposed diversions and road closures. These details will be communicated to the authorities (including the emergency services) and affected residents in advance, via the pre-construction community meeting, and will be properly signposted.

The police will be consulted regarding heavy plant movements.

For residents that are located immediately adjacent to the BTC Marine Terminal, within BOTAŞ property, or those that are likely to experience a substantial increase in heavy vehicle traffic, additional efforts in consultation will involve the following.

- Meetings will be held with settlement Muhtars and residents; these will be organised at a location accessible by all sectors of the community prior to construction. The local residents will then be informed of the nature and length of activities in the area and provide other site specific information, for example: the construction schedule; the line list of sensitivities within the BOTAŞ property; road diversions and disruption to other services; construction staff code of conduct; dates of future community meetings; the Complaints Procedure.

- A notice board will be established in each settlement and all relevant project information will be posted and kept up to date.

- A safety briefing will be provided at settlements adjacent to the marine terminal development, residents within the BOTAŞ property and residents that will experience a substantial increase in heavy traffic. This will cover safety aspects of the construction, including road safety. All sectors, or representatives thereof, of the community will be invited to the briefing.

- Monthly meetings will be held with community leaders and members to provide information on progress and to provide a channel for issues and queries regarding construction to be raised.

- As part of the dispute resolution procedure, a key contact point for resolution of specific disputes with local residents if/when they arise, will be notified to the local residents.

- A fortnightly community impacts report will be submitted to the Employer's Community Relations Supervisors.

- As part of the implementation of the Traffic Management Plan, a monthly report on traffic related issues will be prepared and distributed.

12.8.3.2 Access roads

Existing access roads will be used to transport personnel, material and equipment wherever practicable. This will reduce the need to construct new projects roads, and will help reduce possible impacts of the removal of vegetation on the environment. However, the new facilities will need to be constructed without undue traffic-related conflict with the existing terminal. As a result, both temporary and permanent access roads will be constructed, operated and where necessary, reinstated in accordance with the provisions of the Traffic Management Plan. Where the requirement for temporary access routes proves necessary, they will be set up to maintain appropriate access for pedestrians, cyclists, motorists and livestock. Access to commercial and residential properties will be maintained.

12.8.3.3 Personnel movements

Construction workers will be drawn from the local workforce to the maximum extent practicable in order to minimise impacts from personnel movements. An employment strategy is outlined in Section 12.10, which identifies that the settlements most likely to be affected by the project will be employed first, including those living in the Ceyhan and Yumurtalik districts and the Adana province.

12.8.3.4 Oversized loads

All transport activities requiring 'Long and Heavy Vehicle Transport' will be in accordance with the requirements of General Directorate of Highways and Turkish Highways Traffic Regulation.

12.8.3.5 Other issues

- Traffic flows will be timed to avoid periods of heavy traffic flow along main roads.
- Statutory vehicle limits will be complied with (eg width, height, loading, gross weight and speed).
- Clear signs and signals will be set up where necessary.
- Any road damage will be repaired.

- The spread of dust will be minimised by measures including the sheeting, surfacing of temporary roads and wetting of such areas.

12.8.3.6 Traffic Management Plan

The project's Traffic Management Plan (TMP) identifies the generic measures to be adopted throughout the project to mitigate impacts associated with the project (see Appendix C5). The TMP identifies:

- relevant traffic management policies and standards;
- the potential traffic impacts of the project;
- appropriate measures and procedures for mitigating the impacts.

The TMP addresses the following broad areas:

- access to construction areas;
- routing of construction traffic;
- temporary traffic control and management;
- road crossings;
- parking facilities;
- keeping highways clean of mud and dust;
- reducing the probability of traffic accidents.

The Construction Contractor will be required to use the TMP as the basis for undertaking a detailed Traffic Assessment (TA) and preparing an updated TMP identifying specific measures to mitigate any predicted impacts. The ultimate TMP produced will include detailed procedures that demonstrate how the impacts of traffic on local residents have been taken into consideration.

The TMP will be reviewed and regularly updated as the construction programme is developed and vehicle movement requirements are identified in detail and then on an ongoing basis through the construction phase.

12.8.4 Operational impacts

The existing on-site traffic flows resulting from operation of the existing BOTAŞ Marine Terminal are low. The BTC Marine Terminal interface will comprise approximately 100 persons and the majority of this workforce will be resident on site. Currently, approximately 780 employees travel to and from the BOTAŞ Marine Terminal each day. The BTC Marine Terminal operation will add a very small increment to this number; hence, traffic impacts during operation of the expanded terminal will therefore be minor.

12.9 CULTURAL HERITAGE

12.9.1 Introduction

Dedicated archaeological studies carried out for the BTC Project have identified no significant sites at or adjacent to the proposed BTC Marine Terminal. As such, the potential for impacts to cultural heritage is considered to be low.

However, it is widely acknowledged that the potential exists for unknown sites or features to be revealed during ground disturbances, even in areas where desktop research and non-

intrusive field surveys have identified no evidence of the presence of buried archaeological resources. As a consequence this section outlines mitigation designed to minimise impacts to cultural heritage in the event of an unexpected find.

12.9.2 Construction impacts and mitigation

Although it is not currently anticipated that archaeological remains will be encountered during construction of the terminal, the chance find procedures contained within the Cultural Heritage Management Plan (CHMP) (see Appendix C7) will be applied, as necessary. In addition, the CHMP makes provision for further archaeological surveys (intrusive, geophysical etc), which will be undertaken prior to construction to minimise the potential for unknown finds, to conduct the salvage excavations of identified archaeological sites and significant archaeological features possibly encountered during construction.

Key features of the CHMP include the following measures:

- Archaeological advisors will monitor all topsoil stripping and a 'watching brief' will be kept. Appropriately qualified and experienced archaeological specialists will fulfil this role. In addition, BOTAŞ will appoint archaeological supervisors who will oversee and monitor the implementation of the CHMP.

- Should archaeological remains be encountered, work will be stopped and the finds will be reported immediately to the relevant Museum Directorate and to BOTAŞ' archaeological supervisor, who will advise on the necessary course of action.

- Where archaeological discoveries are made, and by instruction of the relevant Museum Directorate representative, parts of the construction area may be demarcated to allow safe working for archaeological recording. This will normally be undertaken within the normal construction programme. In some areas, this may involve restriction of the construction area.

- If significant remains are discovered that cannot be recorded within the normal programme, it may become necessary, by instruction of the relevant Museum Directorate representative, for the Contractor to provide protection of deposits by provision of 'bog mats' or stone tracks.

- The use of metal detectors will only be allowed with the written permission of BOTAŞ. No unauthorised use of metal detectors will be tolerated.

- Archaeological briefings will be given for all construction personnel working in archeologically sensitive areas.

12.9.3 Operational impacts and mitigation

There is no scope for impact to archaeological resources during operation of the terminal. This is due both to the absence of identified receptors, as well as the nature of terminal operations, which are non-intrusive.

12.10 WASTE MANAGEMENT

During construction and operation of the BTC Marine Terminal, a variety of solid wastes will be generated and will require appropriate management.

An inventory of wastes classified by source, type and hazard is given in the Waste Management Plan (WMP) (see Appendix C3). At this stage the likely volumes of wastes arising have not been quantified. Improper waste management can lead to a number of potential impacts, including:

- soil contamination;
- surface and groundwater contamination;
- visual and aesthetic impacts due to trash and litter;
- health and safety hazards to humans, livestock and wildlife;
- air quality impacts through inappropriate combustion;
- pressures on existing waste management capacity.

The WMP (see Appendix C3) has been developed for marine terminal construction and operation and aims at avoiding the above impacts or reducing them to an acceptable (minor level).In the first instance the WMP is based on a management hierarchy whereby the priority will be to:

1. avoid generating the waste in the first place;
2. minimise the amount that is produced;
3. recover wastes through recycling and reuse;
4. treat and process the waste, without causing secondary impacts to soils, water resources and air quality;
5. dispose of the waste in a controlled way (ie to a licensed facility), without compromising existing waste management capacity.

Solid waste management is controlled in Turkey through several legal instruments:

- Solid Waste Regulation;
- Regulations Regarding the Control of Hazardous Waste;
- Regulations on the Control of Medical Waste.

Implementation of the WMP will be fully in accordance with the requirements of Turkish Legislation.

Full implementation of the WMP will ensure that potential impacts will be minor. However, there are uncertainties to be resolved mainly associated with the volumes of wastes that will arise and current capacity of existing waste management facilities to accept them. To address this, in advance of construction commencing the Marine Terminal Construction Contractor will finalise the WMP, especially taking into consideration the following matters:

- The Construction Contractor will quantify waste volumes by type and the rate at which they will arise.

- The Construction Contractor will demonstrate that to the maximum practical extent avoidance, recycling and reuse will be fully applied.

The Construction Contractor will determine that use of off-site waste disposal facilities is sustainable and will not compromise capacity and conflict with other users.

12.11 DEMOGRAPHICS AND MIGRATION

12.11.1 Community relations

12.11.1.1 Impacts

Good relations with neighbouring residents is increasingly recognised as essential to the overall success and smooth functioning of a project, during both construction and operation. Efforts to establish good relations is consistent with the philosophy that the Project (including workers) are guests in the project area and the local residents their hosts.

The feedback from the surveyed settlements was largely positive towards the Project, although expectations of employment and other project benefits are high. Although mechanisms for managing expectations will be adopted, the key to establishing and maintaining good relations with local residents lies in minimising the negative impacts of the Project through the implementation of the mitigation measures identified in this report. However, on a construction project of this scale, unexpected events will always occur. Establishing and maintaining good relations with local residents, within a framework of on-going communication, will enable these events to be rapidly identified and resolved. Plate 12. to Plate 12.8 illustrate the proximity of neighbouring settlements and the existing BOTAŞ Marine Terminal and Box 12.3 describes the nature of relations.

Box 12.3 Relationship between the Existing BOTAŞ Marine Terminal and Neighbouring Settlements

The existing BOTAŞ Marine Terminal is largely self-contained and the extensive grounds include housing for staff and their families, recreation facilities, a shop and a primary school. However, there is interaction with the neighbouring settlements, namely:

- local residents are able to send their children to the primary school;
- a BOTAŞ bus transports children from neighbouring settlements (along with BOTAŞ Marine Terminal children) to secondary schools in Ceyhan and Adana;
- local residents are permitted to cut grass inside the fence of the BOTAS Marine Terminal to use as animal fodder;
- BOTAŞ management are in contact with local Muhtars and, when possible, assist with the provision of equipment for settlement projects.

However, during consultation local residents expressed concerns regarding the lack of employment of local people at the existing BOTAŞ Marine Terminal and limited opportunities to provide the terminal with goods and services. Very few locals are amongst the 940 people currently employed at the existing BOTAŞ Terminal and most services are contracted out, further limiting the opportunities for locals to secure employment at the facility. This is a growing frustration for the local people, many of who report having invested in their children's education in the hope that this will enable them to secure employment.

(Source: Consultation meetings and existing BOTAŞ Marine Terminal staff)

12.11.1.2 Mitigation objectives: during construction

The objective of the Community Relations Programme in the construction phase will be:

- To provide settlements affected by the Project with regular information on the progress of work and implications for local residents;
- To inform the Project/contractors of any settlement related issues that may impact on construction;
- To monitor implementation of mitigation measures and the impact of construction via direct monitoring and feedback from local residents;
- To identify any significant new issues that may arise during the construction period;
- To manage any disputes between the Project/contractors and local residents;
- To take advantage of opportunities for construction activities to deliver benefits to local residents.

Box 12.4 Settlements Directly Affected by BTC Marine Terminal Construction

Settlements directly affected by marine terminal construction are those that are:

- directly adjacent to the marine terminal development (this excludes residents within the BOTAŞ property);
- likely to experience a substantial increase in heavy traffic as a result of construction activities;
- within 5 km of a construction camp/s.

Those settlements that are directly adjacent to the marine terminal are Golovasi (and Sahil Sitesi), Incirli and Karatepe. Location of the construction camps and access roads will be finalised in negotiation with the Contractor. Affected settlements are therefore not currently known.

Plate 12.5 Karatepe Settlement and the BOTAŞ Tank Farm and Property Boundary

Plate 12.6 BOTAŞ Jetty Support Vessels and Incirli Settlement in the Background

Plate 12.7 BOTAŞ Main Gate and Incirli Settlement in the Background

Plate 12.8 View Towards Golovasi / Sahil Sitesi Port from BOTAŞ Property Boundary

12.11.1.3 Mitigation measures: during construction

To meet the mitigation objectives, a Community Relations Programme will be established for implementation by the Contractor, BOTAŞ and BTC Co. Aspects of the Programme for implementation by the Contractor will be developed in more detail in the Contractor's Community Relations Plan. Aspects of the Programme for implementation by the Project will be implemented on the basis of the Community Liaison Management Plan in Appendix C8.

Division of responsibilities

The responsibility for the community liaison programme and employment of community liaison staff will be divided between BOTAŞ, the BTC Co and the Contractor.

The Contractor will have day-to-day responsibility for community liaison and will be the principal point of contact with affected settlements. The Contractor shall appoint a full-time dedicated Community Liaison Officer(s) (CLO) for the co-ordination of project public relations and external liaison needs. The Contractor shall appoint additional CLO(s) as required in order to fulfil the Scope of Work detailed in the Social Management and Monitoring Plan (SMMP). (see Appendix C8). Furthermore, the CLO(s) will manage the good reputation of both BOTAŞ and the Contractor. This position shall report directly to the Contractor's Project Manager including regular, on-going liaison with the BOTAŞ Community Relations Manager. In addition, the CLO(s) shall liase with third parties who are or may be affected by the execution of the Works, as well as interface with landowners.

At the present time it is envisaged that there will be one contract for both the construction of the onshore facilities and the offshore facilities.

BOTAŞ and BTC Co will also appoint staff with responsibilities for Community Relations. (see Table 12.5) in accordance with the role of BOTAŞ as the Turnkey Contractor and the assurance role of the BTC Co, the team will consist of the following:

- **BOTAŞ:** One Community Relations Manager (CRM), supported by a Community Relations Supervisor(s) (CRS), responsible for overseeing all works carried out by the contractors during construction of the marine terminal. There will also be one CRS based in the BOTAŞ office full time in order to deal with free-phone inquiries related to the marine terminal, the pipeline and associated Above Ground Installations (AGIs)

- **The BTC Co:** A Community Relations Manager (CRM) who will oversee all community relations activities for the BTC Project (marine terminal and pipeline), supported by seven environmental and social inspectors

The Community Relations Team of the Project will be empowered to stop works if they are of the opinion and can demonstrate that the requirements of the SMMP have been deviated from.

In order to carry out the required pre-construction activities, the Community Relations Manager has been appointed. The Community Relations Supervisors will be appointed immediately following contract award. The CLOs will be appointed no later than one month prior to construction (ie during the construction mobilisation phase of the Project).

The CLOs will be Turkish speaking, preferably with an understanding of the project area. They will preferably be graduates with a degree or diploma that has a social focus, with proven field skills in communications and a minimum of two years relevant experience, preferably in community relations. A minimum of one in every three CLOs will be female. The Contractor shall assign CLOs of adequate competency.

Table 12.5 Roles and Responsibilities with regard to Community Relations

Contractor: Responsible for Adhering to Requirements of SMMP

- Provide primary interface between Project and affected settlements.
- Coordinate and implement required pre-construction activities, namely:
  - produce management plans for community relations, construction camps and transport;
  - train staff with community relations responsibilities;
  - implement induction training workshops for all construction staff.
- Assist in local recruitment process.
- Ensure on-going communication with affected settlements through the following activities:
  - Meet with settlement leaders and hold community meetings prior to arrival of construction teams in a given locality to inform local residents about construction activities, work schedule, construction staff Code of Conduct, Complaints Procedure, safety issues, dates of future meetings and contact details of Community Liaison staff.
  - Hold regular meetings with directly affected settlements during construction to provide information on progress and provide a channel for issues and queries to be raised.
- Liase with contract representatives on major issues arising and ensure that local residents are kept informed of any expected or unexpected disruption through leaders and by maintaining a community notice board.
- Provide a focus for negotiation and resolution of specific disputes with residents if/when they arise, using the Complaints Procedure.
- Submit fortnightly and monthly community impacts report to the Project.

BOTAŞ: Overall Accountability

- Assist the contractors to develop community relations procedures prior to construction start-up, including required management plans, recruitment procedures, contracting procedures, CLO recruitment and training.
- Agree dispute resolution process with the Project, Contractor and settlements.
- Monitor implementation of/adherence to all relevant management plans through liaison with the Contractor and meetings with affected settlements.
- Identify breaches of management plans and recommend corrective action. Stop the work in the event of breaches that may cause serious impacts on local settlements or on the reputation of the project.
- Track the social impact of the project against the BTC Objectives and Key Performance Indicators (KPIs) as stipulated in the SMMP and work with the contractors where amendments to the mitigation measures are required.
- Monitor processing and resolution of complaints and ensure alignment across the project with Complaints Procedure.
- Provide regular information to the BTC Co on performance.
- Represent the Project at community meetings.

BTC Co: Monitoring and Assurance

- Review all community relations procedures compiled by contractors.
- Monitor performance through review of information provided by BOTAŞ (including performance against KPIs and targets), field observations and community meetings and submit recommendations for amendments or additions to community relations procedures.
- Make information on the project available to the public, including performance against KPIs.
- Monitoring and assurance of the processing and resolution of complaints.
- Monitor working practice of project security team.
- Monitor recruitment and contracting processes.
- Provide regular information to BOTAŞ Site Managers on performance.
- Assist at community meetings where necessary.

Complaints procedure

The Contractor will aim to prevent formal complaints through the community liaison mechanisms outlined above. In addition, a formal complaints procedure will be set up to enable any complaints to be made directly to the Contractor's CLO. Details of the free-phone telephone number and complaints procedure will be distributed to all settlements, landowners and occupiers in the vicinity of the marine terminal site and construction camps and close to roads that will experience significant increases of traffic movements (see Appendix A1, the PCDP, for more detail on the Complaints Procedure).

The telephone shall be answered in person and details of the complaint, source, location and date/time of offending event recorded. The Contractor's CLO will investigate the complaint in the first instance. All complaints received by community members or local authorities will be processed and resolved within seven days.

To accommodate those that do not have access to a telephone, the Complaints Procedure addresses both written and verbal complaints (if delivered in person). Responses will be provided in writing or verbally, depending on what is more appropriate (eg if the complainant is illiterate, a verbal response will be provided).

Projected affected settlements will also be provided with contact numbers for BOTAŞ in the event that the Contractor does not satisfactorily handle a complaint within seven days. The complaints procedure will include the right to third party arbitration, funded by the Project.

12.11.1.4 Mitigation objectives: during operation

The objective of the community relations programme in the operational phase will be to:

- maintain constructive relationships between local residents and the marine terminal operators, to assist in the operation of the terminal;
- maintain awareness of safety issues among local residents neighbouring the marine terminal and those along the access roads likely to experience a substantial increase in traffic;
- monitor attitudes of local residents to the marine terminal and operating company.

12.11.1.5 Mitigation measures: during operation

Community liaison activities undertaken during operation will be developed during the construction phase based on experience during this time. However, it is likely that they will consist of the following:

Ongoing community liaison

An employee at the marine terminal will be responsible for community liaison activities. Their responsibilities will include holding regular meetings with settlements to identify any issues and concerns. They will also be responsible for identifying appropriate ways for the terminal to be a good neighbour. This could include, for example, working with the local settlements to maximize local sourcing of goods and materials, having open days to explain how the terminal functions, providing briefings in schools or using available equipment to carry out small tasks as part of wider settlement projects.

Community relations hotline

A free-phone number will be displayed in all settlements neighbouring the marine terminal to report any grievances, concerns or suggestions for improvement. It will also be provided to the Jandarma (local security forces) and emergency services. Telephone calls will be answered by a person who will take the details of the caller and of the issue. The caller will be informed of the actions taken.

To accommodate those that do not have access to a telephone, the dedicated community relations employee will be available to receive both written and verbal complaints. Responses will be provided in writing or verbally, depending on what is more appropriate.

Reporting and availability of information

The operating company will develop short annual briefings that identify any issues associated with the marine terminal and its operation.

Prior to decommissioning

The operating company will carry out a study prior to de-commissioning to identify and mitigate any negative impacts resulting from de-commissioning.

12.11.1.6 Residual impacts

Maintaining good relations offers the following key benefits for both the Project and neighbouring settlements:

- Increased cooperation from local residents;
- Early warning of potential problems, with the Project more likely to be given the benefit of the doubt when problems arise;
- A cooperative approach to problem solving;
- Refinement of mitigation measures and resolution of complaints;
- Decreased cause for protest action from neighbouring settlements.

12.11.2 Construction workers and construction camps

12.11.2.1 Impacts

Overview

The preferred location for the construction camp is within the existing BOTAŞ property (see Box 12.5). Should alternative locations be investigated or additional camps proposed, it is the responsibility of the Construction Contractor to review key criteria guiding site selection prior to the finalisation of the construction campsite. The criteria will be included in the agreement of the Contractor.

Box 12.5 Size of Construction Camp

Only semi-skilled and skilled workers will be housed in the construction camp. Unskilled workers will be sourced from the local settlements and will therefore not require housing. The total number of workers housed in the camp will be 300 (225 workers for on shore construction and 75 workers for off shore construction). A total area of 700m x 250m of land within the BOTAŞ property will be required for the establishment of the construction camp.

(Source: BOTAŞ, Ankara office)

On the whole, the community consultation process indicated positive attitudes to a construction camp neighbouring local settlements, with residents expecting to secure project benefits as a result (eg preference for employment and provision of local goods to construction staff) (see Box 12.6). However, residents did raise concerns regarding the conduct of the workforce and the potential for this to conflict with the socio-cultural values of local residents.

Box 12.6 Attitudes of Local Residents to Location of Construction Camps[1]

The preliminary results of consultation indicated that, on average, 72% of surveyed households welcomed the location of a construction camp nearby, while 28% of the surveyed households indicated that they would not. Among the settlements directly adjacent to the existing BOTAŞ Marine Terminal, 50% of respondents in Golovasi were not in favour of a construction camp nearby, followed by Incirli (35% of respondents), Sahil Sitesi (13% of respondents) and Karatepe (11% of respondents). Among the indirectly impacted settlements, Sugozu recorded the highest percentage of respondents not in favour of a construction camp (44%). All respondents interviewed in Karayilan were in favour of neighbouring a construction camp.

(Source: Household Survey)

Settlements neighbouring the construction camp, namely Karatepe, Golovasi, Incirli and Sahil Sitesi will be targeted for preferential employment (and sourcing of goods and services, where possible), and will benefit from increased clientele for local retailers, including convenience stores, local markets and restaurants. However, in spite of these benefits, the possibility of tension and conflict developing between local residents and the workforce does exist. This tension could be caused by the following factors:

- Impacts of project activities on local infrastructure and services;
- Higher standards of living enjoyed by construction workers and resultant resentment from poorer neighbouring settlements;
- Incidence of prostitution in the vicinity of the construction camp;
- Spread of communicable diseases brought in by the outside workforce.

[1] Current findings on attitudes to the location of construction camps are considered preliminary, as this issue was not a specific focus of consultation. Additional consultation on this issue is therefore required once a potential site/s has been identified.

Box 12.7 Factors Mitigating Against Additional Tensions

The settlements neighbouring the proposed BTC Marine Terminal have already experienced the development of the existing BOTAŞ Marine Terminal and are located within an area subject to increasing levels of industrialisation. These settlements are no longer isolated from outside influences and are becoming increasingly familiar with large-scale development projects. As a result, disturbance due to socio-cultural differences (between the workforce and resident population) is not expected to be a common source of tension. Furthermore, settlements within the project area (eg Golovasi, Sahil Sitesi and Incirli) are currently engaged in tourist activities and are therefore accustomed to an influx of Turkish tourists and the differing socio-cultural values that this sometimes brings.

(Source: Settlement Level and Household Questionnaires)

The potential area of influence of the construction camp can be divided into three categories of settlements. These are:

- Settlements that fall within a 5km radius of the construction camps (including directly adjacent) and are therefore accessible on foot from the camp. Factors such as topography, road network and access to settlements from the construction camps will affect the likelihood of these settlements being reached. Settlements in this category include: Golovasi, Sahil Sitesi, Hamzali, Kurtkulagi, Kurtpinari, Karayilan, Karatepe and Incirli.

- Settlements located within driving distance (assumed to be within a one hour car journey) of the construction camps. This could be an issue during days off when construction staff have the opportunity to drive further distances. This is likely to apply only to larger towns/district centres which have the potential to attract construction staff for purchasing of supplies, entertainment etc. Settlements include: Ceyhan, Yumurtalik, Yakapinar, Imamoglu, Osmaniye, Yesilkent, Dortyol and Adana.

- Settlements located along the access roads (this applies to access roads that fall outside of the 5km radius specified above), which include Ceyhan, Adana, Osmaniye etc.

Infrastructure and resources

Impacts of Project activities on local infrastructure and resources are a possible source of tension between the workforce and the resident population, in particular, increased traffic congestion. The Project will, however, be largely self-sufficient, thus mitigating against any tensions developing in this regard.

Higher standards of living in the construction camp

The community consultation process highlighted resentment among local residents regarding the high standards of living enjoyed by residents (employees and their families) within the existing BOTAŞ Marine Terminal. This resentment needs to be understood within the following context:

- The low standards of living currently experienced in neighbouring settlements.

- Discontent regarding the low proportion of local residents employed during the construction and operation of the existing terminal. Dissatisfaction on this issue was

fuelled by the lifestyle changes experienced by BOTAŞ employees and witnessed by residents of neighbouring settlements.

Given the history, the relatively high standards of living in the construction camp has the potential to impact on relations between neighbouring residents and the construction workforce and/or the Project, and could affect relations during the operational phase.

Prostitution

The potential for increased prostitution as a result of the BTC Project is considered to be low, particularly in the vicinity of rural settlements where local residents are generally conservative and thus unlikely to tolerate such activities. In the district and provincial centre, brothels are controlled by the government and include the implementation of regular health checks for all sex-workers.
Communicable diseases

All personnel, including sub-contractors, will be required to undergo health screening. No-one suffering from a transmittable disease will be allowed to work on the project The Contractor will also be required to conduct regular health awareness training and personal health programmes (including check-ups and immunisations) in order to prevent illness occurring or spreading among the workforce. This will include awareness on HIV and STDs. These efforts will assist in ensuring that an increase in communicable diseases among neighbouring settlements, as a result of the construction workers, is kept to a minimum. It should also be noted that previous exposure to an outside workforce, as a result of existing developments in the project area, is expected to have increased the resistance of local residents to communicable diseases.

12.11.2.2 Significance criteria

Tension between construction staff and local residents will be considered significant if the conduct of the workforce is perceived by local residents to be offensive or giving cause for complaint. In addition, such tensions will be considered significant if they result in any one of the following:

- any legal action initiated by local residents against the Project and/or the construction company;
- disruptions to construction works by local residents;
- outbreaks of conflict and violence, including injury or damage to property.

Although unlikely, an increase in communicable diseases will be considered significant if local health services are not able to effectively treat or contain the outbreak of such diseases.

12.11.2.3 Mitigation objectives

In order to address the potential impacts that might be caused by construction workers, the following mitigation objectives have been agreed to by the Project:

- To ensure that construction crews behave in a way that is consistent with the recognition that the local population are their hosts and the contractors are guests in the project area.

- To prevent any negative impacts that could potentially accrue as a result of the presence of construction workers in the project area.

- To maintain effective dialogue between Construction Contractors and local residents such that potential issues can be rapidly identified and resolved (See Section 12.10.1, Community Relations).

12.11.2.4 Mitigation measures

The majority of the measures required to prevent impacts associated with construction workers are the responsibility of the Contractor and will be included in their contract for incorporation into their management plans. These requirements, plus additional mitigation measures that are the responsibility of the Project, are identified below.

Location of Construction Camps

The camp will be placed within the existing BOTAŞ property, therefore the impact on local infrastructure and utilities will be minimal. In the event of alternative locations being considered or additional camps proposed, they will be located at least 2km from any settlement, wherever possible. Settlements within 5km of the construction camp will be consulted to assess and/or verify their levels of acceptance regarding the nearby location of the camp during the public disclosure process. This consultation will be coordinated and facilitated by the Project. If settlements show strong resistance to the proximity of a construction camp, camps will not be located within 5km of these settlements, where practicable.

There will be on-going community liaison by the Contractor as part of their community liaison responsibilities (See Table 12.5).

Code of conduct

In order to minimise social disturbance from the behaviour of construction workers, a worker Code of Conduct will be drawn up. This will include:

- respect for local people and customs;
- zero tolerance of bribery or requests for gifts from local residents;
- no hunting, fishing or unauthorised gathering of products;
- zero tolerance of illegal activities by construction personnel, including illegal prostitution, illegal sale or purchase of alcohol, and sale, purchase or consumption of drugs, illegal gambling or fighting;
- no use of camp vehicles for non-work business and no use of personal vehicles for work business, unless authorised by the camp manager;
- limitations on hours of movement and use of security passes;
- no access to camps for non-authorised personnel;
- no purchase of goods or services at the camp gate;
- an alcohol and drugs policy (both in and out of work hours);
- rules on access to and use of camp entertainment facilities;
- country wide speed limits (10% lower than those legally imposed).

The Code of Conduct will include disciplinary measures for those that break the requirements. The Code will be publicised in settlements potentially affected by the construction workers to help ensure that local residents are aware of the behaviour expected of construction workers. A system for submitting complaints about the behaviour of workers is included in the Complaints Procedure.

Entertainment facilities

The Contractor will provide adequate recreation and entertainment facilities at all permanent camps in order to minimise the potential for 'unruly' behaviour amongst construction workers outside the camp. A limited volume and selection of alcoholic drinks may be available to workers in camps to discourage them seeking alcohol outside the camps. Decisions regarding the enforcement of alcohol free camps will be left, however, to the discretion of the Contractor, as this practice is common in Turkey.

Induction training

Training will be provided to all staff, both national and expatriate, on camp management rules, overall discipline and cultural awareness. Induction training will include:

- a briefing on Camp Rules;
- training on BP Health, Safety and Environment (HSE) policies and procedures;
- a community relations orientation. The objective of this orientation will be to increase awareness about the local area and about the Code of Conduct.

Workforce health strategy

The Project will develop and implement a Disease Awareness and Prevention Strategy in liaison with government health authorities and other expert health organisations in Turkey. This will include:

- health screening for all personnel;
- health awareness training for workers (including HIV/AIDS and other STDs) at induction and then periodically throughout their employment;
- a personal health programme for workers including check-ups and immunisations, if required;
- awareness-raising on health issues for settlements close to camps (via posters, leaflets, through health clinics, community meetings etc);
- condoms will be available, without charge, from the camp doctor [1] ;
- on-going liaison with local health authorities.

Use of camp facilities and services

Entry to construction camps will be strictly limited to the workforce. In the event of a medical emergency being brought to the camp, the medical staff will offer immediate emergency medical support and lend reasonable assistance in organising transport to health services.

Benefits to local settlements

By way of mitigation against possible resentment towards workers enjoying relatively higher standards of living in the construction camps, the Project will seek to bring benefits to local settlements. This will be done through:

1 The camp doctors recruited by the Construction Contractor will be recognised members of a Chamber of Medicine associated with the Turkish Medical Association.

- linking project infrastructure needs into existing infrastructure and service plans (eg road upgrades, sewerage treatment, waste management and water supply), thus resulting in long-term benefits for local settlements;

- the implementation of a Community Investment Programme by BTC Co, the objective of which is to have a positive impact on settlements most affected by construction activities by providing direct benefits, and by engaging with and adding value to local settlements in a sustainable way. This will be done via Sustainable Development Projects and Local Community Projects;

- the Employment Strategy, which will require the Contractor to maximise the use of local workforce on the project. Settlements directly affected by the marine terminal will have priority, followed by workers in Ceyhan and Yumurtalik districts and then Adana province.

12.11.2.5 Residual impacts

Even with full implementation of the mitigation measures, it is likely that there will be negative residual impacts arising from specific incidents or disputes between construction workers and local residents. However, the Project is committed to identifying and resolving incidents and disputes in order to maintain the confidence of the local settlements and the discipline of the workforce. This should ensure that any negative impacts are short-term.

With regard to health, the implementation of the identified migration measures will ensure that the residual risk of an increase in communicable diseases is very low. This low risk will also be offset by the training that the Project will deliver to approximately 400 workers in health and safety (including hygiene, HIV/AIDS awareness) as well as to settlements neighbouring the BTC Marine Terminal.

12.11.3 In-migration Impacts

Overview

Large-scale developments can directly or indirectly attract temporary or permanent in-migration into the area. The main drivers of in-migration will be the following:

- People travel to the project site in search of direct employment or to sell goods or services to the workforce.

- Non-local workers bring their families to nearby locations and remain after the end of the project.

The likelihood of in-migration as a result of the proposed BTC Marine Terminal should be assessed in light of the fact that the existing BOTAŞ Marine Terminal has been in operation for 26 years[1], employing approximately 1,000 people. In spite of this development and potential employment opportunities (perceived or actual), the project area shows very little sign of in-migration. Only Incirli has slightly higher male ratios, which could reflect previous in-migration. The absence of large-scale in-migration under the existing conditions indicates

[1] The Ceyhan Marine Terminal commenced operation in 1976, with the first tanker being loaded on the 25 May 1977 (http://www.BOTAŞ.gov.tr).

that a sudden influx of job seekers to the project area[1] is unlikely to occur as a result of the BTC Project.

What is expected, however, is a more gradual influx of job seekers to the Iskenderun Gulf area, including the project area, as a result of on-going industrialisation. With the identification of the Iskenderun Gulf area as an industrial zone, the way of life is expected to change from a predominantly subsistence based to an increasingly industrial and urban based one. There are already a number of developments (existing and proposed) in the immediate vicinity of the project (see Section 11).

Any in-migration and associated impacts are therefore likely to be caused by cumulative industrialisation, of which the BTC Project is a part, rather than as a result of the marine terminal development itself. However, as a precautionary principle, impacts associated with possible in-migration to the project area have been assessed and associated mitigation measures developed.

Impact description

The potential impacts of in-migration are directly related to the capacity of the existing services and resources to support an increased population, and the ability of the resident population to adapt to any changes to standards of living and sources of livelihood. An overview of conditions in the project area indicates that the existing services and resources are not sufficient to meet the needs of either the current or additional populations.

Conditions within the project area are summarised below:

- Services in the project area (piped water, sewerage, waste and health facilities) are insufficient for the existing residents and, based on their current capacity, will not be able to accommodate a substantial increase in population.

- The project area is also characterised by a low availability of sources of livelihood (income and subsistence based). In particular, there is limited availability of agricultural land (due to uneven distribution), and thus limited options for agriculture, and decreasing fish stock in the Iskenderun Gulf. Results from the settlement and household level surveys indicate that these conditions are already manifesting themselves in a deterioration in standards of living and high debt levels, with an associated increase in the incidence of depression and alcoholism among men.

The extent to which these conditions will be exacerbated by an in-migration of job seekers is dependent on three factors:

- Whether or not the migrants are able to secure formal employment.

- Whether or not the migrants, in the absence of formal employment, attempt to secure a subsistence livelihood, thus competing with local residents.

- Whether existing residents are able to secure formal employment, thus becoming less dependent on subsistence based livelihoods.

It is expected that the migrants, if failing to secure a wage income, will mostly return to their place of origin. For those that remain, the limited avenues for participation in

[1] For the purposes of this assessment, the project area refers to those settlements that neighbour the proposed marine terminal,ie Golovasi (and Sahil Sitesi), Karatepe and Incirli. Where the assessment goes beyond this geographical boundary, this will be highlighted.

subsistence-based livelihoods will limit the extent to which they impact local resources in the area. The most likely impact is therefore expected to be increased pressure on services in the project area[1] as a result of both unemployed migrants who remain in the hope of later employment, as well as employed migrants who choose to reside in the project area.

12.11.3.1 Impact summary

The likelihood of a large influx of job seekers to the project area as a direct result of the BTC Marine Terminal is *low*. However, the likelihood of a gradual influx of job seekers to the Iskenderun Gulf area, including the project area, is considered to be *high*. In-migration to the project area could potentially result in a loss of the following types of assets:

- **Natural capital**: if migrants undertake fisheries based activities this will put additional pressure on already over-stretched resources.

- **Physical capital:** additional people will increase the pressure on services that are already overstretched.

- **Financial capital:** increased competition for subsistence and wage-based livelihoods could impact on the amount of income generated from these activities.

- **Social capital:** competition for subsistence-based and income-based livelihoods could also result in tension and possible disputes between residents and newcomers, and/or between existing residents.

- **Human capital:** no change predicted.

In-migration may, however, result in improved financial capital due to increased clientele and expenditure in the project area. These benefits will mostly go to local retailers and farmers, and possibly to fishermen, although their benefits might be less as they reportedly have to sell the majority of their catch through local traders.

In the absence of mitigation, the ability of residents within the project area to absorb any potential loss of capital is likely to vary between individuals. Those dependent upon resource based livelihoods (eg fishing) are likely to have a *low* ability to cope with changes, whereas those involved in commercial and/or retail activities are expected to benefit from an increase in clientele. Their ability to adapt is therefore considered to be *high*. However, an ability to cope with a deterioration in service provision is considered *medium* for residents that can afford alternatives (eg purchase of alternative fuel sources, transportation to district centres for health care, sending children to more distant schools) and *low* for the poorer households, who cannot afford these alternatives.

12.11.3.2 Significance criteria

The occurrence of in-migration will be considered significant if:

- the ratio between number of people and capacity of local services exceeds levels considered acceptable by the relevant authorities;

[1] Although the potential for the development of informal settlements in the wider Iskenderun Gulf area does exist (as a result of in-migration), this is unlikely to take place in the project area due to the high security that would be in place for both the existing and proposed terminal.

- there is a recorded increase in levels of unemployment. (key indicators are decreased salary income and decreased numbers of hours worked within settlements neighbouring the proposed BTC Marine Terminal[1]);

- incidents of conflict over access to resources are reported to have occurred within settlements neighbouring the proposed BTC Marine Terminal.

12.11.3.3 Mitigation objectives

- In order to address the potential for in-migration to the project area, the Project has committed itself to discouraging in-migration in search of employment or other project benefits (eg provision of local goods).

12.11.3.4 Mitigation measures

Employment Strategy

The Project will actively discourage informal in-migration in search of employment opportunities. They will develop and publicise an employment strategy in appropriate media, and via direct notification of sub-governors and Muhtars within Adana Province and governors within Turkey. It will contain the following procedures:

- preference for local labour;

- no recruitment at the construction camp or work site. Locations for registration for unskilled work will be within a three-hour journey by public transport for all directly affected settlements (eg Ceyhan district centre or Yumurtalik district centre). Semi-skilled workers to be recruited from provincial centres (eg Adana) or more locally (eg Ceyhan or Yumurtalik district centre). Skilled workers to be recruited in Adana and other national centres.

Purchasing Strategy

The Project will publicise the fact that the contractors will not purchase goods at camp locations or work sites. (See Section 12.13 for more details on purchasing strategy).

Camp Rules

Illegal activities near to camps will not be tolerated. Authorities will be informed and any employees implicated will face disciplinary procedures.

Worker Training

The Project will develop a Disease Awareness and Prevention Strategy in liaison with government health authorities and other expert health organisations. This will include:

- health screening for all personnel, including sub-contractors;

- health awareness training for workers (including HIV/AIDS and other STDs) at induction and then periodically throughout their employment;

[1] State Institute of Statistics, 2002 (www.die.gov.tr)

- a personal health programme for workers including check-ups and immunisations, if required;

- awareness raising on health issues for settlements neighbouring the BTC Marine Terminal (via posters, leaflets, through health clinics, community meetings etc);

- condoms will be available, without charge, from the camp doctor;

- on-going liaison with local health authorities.

The Contractor will be prepared, at the request of the Project, to utilise the camp medical facilities and site medical personnel to provide training and support to local settlements.

12.11.3.5 Residual impacts

The successful implementation of the above mitigation measures will assist in minimising the potential for uncontrolled in-migration to the project area (ie in-migration in the absence of adequate resources, infrastructure and services). However, Turkish citizens are free to move within their own country. As a result, there is a *low* likelihood that there will be limited in-migration directly related to the project and a *high* likelihood that there will be higher levels of in-migration over time due to industrialisation of the Iskenderun Gulf area. In-migration associated with cumulative industrialisation is further discussed in Section 16.

The project will, however, benefit local settlements by raising the awareness of up to 400 workers in health and safety, including HIV and other STDs, many of whom will be from settlements within the project area, as well as residents in settlements neighbouring the marine terminal.

12.11.4 Safety of local residents and BTC workers

12.11.4.1 Impacts

The main safety hazard posed by the construction phase for local residents is the increased traffic on neighbouring roads. This is considered in Section 2.8.

Other safety hazards relate to the construction of the pipeline through BOTAŞ property. Within the property, there is a residential population of approximately 640 people, including facilities for guests. There are no livestock on the property, with the exception of a herd of deer that are kept in an enclosed area.

During construction, there will be an open trench of up to 2.5 meters deep crossing roads within the property. It is likely that the trenches will be left open for about one week at a time. Other hazards include heavy machinery and sharp or otherwise dangerous wastes.

The construction phase also poses safety risks for the BTC workers. However, these risks will be minimized through the compulsory adherence by both contractors and subcontractors to all BP HSE policies and procedures.

12.11.4.2 Significance criteria

Any injuries to local residents and BTC workers will be considered significant.

12.11.4.3 Mitigation objectives

Safety of the workforce and local residents is a priority for the Project. The Project has therefore committed to preventing injury to residents and BTC workers as a result of construction activities associated with the project:

12.11.4.4 Mitigation measures

The hazards posed by construction will be mitigated through a combination of communication with local residents and by implementing good working practices as summarised in the following sections.

Community liason meetings

In the weeks prior to construction, the community liason team will hold meetings with residents within BOTAŞ property and those affected by significantly increased transport loadings. A priority topic will be safety, including both road safety and also an explanation of the hazards posed by construction activities on the working width.

Women's meetings

Particular effort will be made to brief women on safety measures. As the primary caretakers, women are well positioned to pass on safety information to their children. Separate women's meetings will also assist in addressing the sometimes low attendance and participation of women at community meetings These meetings will be held in local schools or in other appropriate locations. In settlements identified as traditional or conservative, efforts will be made to ensure that a female CLO will run the meeting. Information will be provided orally with written material only used to back up key messages.

Roads used for access to schools

The Contractor will identify those roads that are used by children to reach schools. Where these roads are to be used by construction traffic, road safety awareness information and briefings will be provided in local schools. Vehicle traffic will be minimised during hours that children are travelling to and from school.

Securing the worksite

During construction, appropriate measures will be undertaken to ensure the safety of people and domestic animals from accidents caused by machinery or falling into the trench. Hazards will be dealt with on an individual basis. A risk assessment for all construction activities will be carried out prior to the start, especially where heavy equipment is involved. This will ensure that appropriate safety measures are taken to reduce the risks to acceptable levels. Mandatory security measures will include:

- demarcating open trenches with luminous temporary fencing that will act as a warning of the hazard;
- erecting protective barrier fencing on sections that come within 500m of residential areas and in areas where the trench is deeper than 2.5m;
- fencing all crossing points over open trenches;
- securing heavy machinery in an agreed location over night;

- properly store wastes overnight to avoid attracting animals.

BP HSE Training

As part of induction training, all staff (both national and expatriate) will be trained in BP HSE policies and procedures.

12.11.4.5 Residual impacts

The measures identified will minimise the likelihood of serious injury to local residents and the BTC workforce. There may be a residual, although very small, likelihood of injury. In the event of injury caused directly by the project, the Project will be responsible for necessary medical treatment and any compensation, if required.

12.12 LAND OWNERSHIP AND USE

Impacts on land ownership and use will occur if expropriation of land is required for alternative or additional construction camps (ie in addition to the proposed camp within the existing BOTAŞ property). Procedures for this will be dealt with separately as part of land acquisition process.

12.13 EMPLOYMENT, LIVELIHOODS AND SKILLS

12.13.1 Employment

12.13.1.1 Benefits during Construction

Direct employment

The project area is characterised by limited opportunities for wage income, high levels of underemployment and limited opportunities for agriculture. Employment is thus considered to be the most important source of potential benefits that the BTC Marine Terminal development can directly bring to local settlements.

One Contractor will be appointed, for construction of the on-shore facilities and off-shore facilities of the marine terminal. It is estimated that this Contractor will employ a total of between 700 – 1100 workers over a 2-2.5 year period (the peak of the construction phase). This will include those required for construction activities and those required to construct and run the construction camp/s and the overall operation. Each team will require skilled, semi-skilled and unskilled labour.

Table 12.6 provides further information on opportunities for employment during the construction phase. However, it should be noted that the number of workers and the division of skilled, semi-skilled and unskilled labour will depend on the exact construction methods used. These specifics will be determined by the Contractor. The figures provided should therefore only be taken as a guide.

Table 12.6 Estimates of Employment Opportunities during Construction

Task	Numbers of Workers	Skills Mix % (unskilled: semi-skilled and skilled)	Duration (peak employment for semi-skilled and skilled employees only)
BTC Marine Terminal – offshore			
Construction	120 workers	20:80	24 months
BTC Marine Terminal – onshore			
Construction	250 workers	40:60	30 months

Security of livelihoods

Those individuals that secure permanent or long-term employment on the marine terminal will experience increased security of livelihoods. This is particularly relevant for individuals dependent on the following: 1) availability of marine resources; 2) rain as a source of irrigation; 3) seasonal employment; and 4) other sources of livelihood that are vulnerable to climatic conditions and/or economic fluctuations (in terms of selling prices of products). However, these benefits will not be widespread, as employment opportunities associated with the project are relatively low.

Skills upgrade

Construction will require skilled, semi-skilled and unskilled labour. The skilled workers will include welders and machinery operators and workers who will typically require recognised qualifications and 10-15 years experience in pipeline/marine terminal construction in order to ensure the required quality of work. The semi-skilled workers will require more than 5 years experience. Unskilled workers will require no prior construction experience, but are likely to be required to be literate.

Given the relatively long duration of the construction phase, it is expected that there will be opportunities for skills transfer within the workforce. Skills development will, however, be given additional priority during the operational phase. All workers will receive additional skills such as health and safety training and job specific training (eg defensive driver training). All workers will have a minimum of five days HSE awareness training. In addition, Site Foremen/supervisors will receive an extra 3-5 days training on HSE.

Procurement of goods and services during construction

The construction of the marine terminal will require a variety of goods and services. The goods and services that each contractor will require will not be known until after the contracts are awarded, but will typically include:

- catering services to camps and construction sites;
- laundry services to camps;
- security services at camps and construction sites;
- supply of vehicles[1] (including dump trucks, font-end loaders, tractors, trailers, bulldozers and cranes);
- provision of food supplies (indirectly through catering services);

[1] All vehicles will be required to meet the BTC Project standards.

- supply of construction equipment including: compressors; back hoes; bending, bevelling and cutting rigs; drills; generators; ground breaking equipment; road rollers; side booms; pumps; welding machines; X-ray equipment; water tanks etc;
- provision of construction materials including: aggregates/sand; concrete; building materials; local produce; timber and equipment hire.

Indirect benefits and impacts

This employment of local labour will generate the following indirect benefits:

- increased demand for goods and services as a result of increased available income;
- generation of skills and experience that may assist people to secure other employment;
- demonstration that employment can be managed in a fair and transparent manner;
- reduced cost to the project, as local workers do not need to live in construction camps;
- improved community relations.

There are a number of potential negative impacts associated with the employment of local labour. These impacts (listed below) are however considered to be insignificant alongside the benefits that will be delivered to local settlements.

- Workers may give up their normal employment (formal, self-employed or informal) for higher-paid temporary employment during construction of the marine terminal. This can result in the loss of longer-term livelihoods. However, households are considered best able to make decisions about their future wellbeing. The responsibility of the project will be to provide clear information on the limited timescales of employment opportunities.

- Other family members such as children may take over work (eg agricultural work) during the construction period. If children do take over work responsibilities, this could affect school attendance.

- Employment may change the socio-economic status of individuals and disrupt relationships within a settlement. The magnitude of this would depend on the relative size of the income earned by the worker. However, this potential impact is considered insignificant in contrast to the tension that would result should recruitment practices not be open to all.

- Wage levels could potentially be pushed up where there is a shortage of labour, making the contracting of seasonal cultivators too expensive for local landowners. This is not considered to be a significant impact, given the low percentage of temporary labour that will potentially be employed on the project.

- Increased spending power of employees may temporarily increase the cost of local supplies. Again, given the relatively low percentage of the local population that will be employed on the project, this is not considered to be significant.

12.13.1.2 Optimisation objectives

The Project aims to maximise the opportunities for local employment while recognising the varied skill sets necessary for the construction and operation of a marine terminal and other limitations such as the project timetable, financial constraints and safety of the project.

In order to maximise opportunities for employment, the Project have committed to the following objectives:

- to increase employment of country nationals, and in particular, directly affected settlements and residents of the district and province in which the project is being developed. This will be subject to availability of appropriate skills;

- to establish recruitment procedures that are transparent, public and open to all regardless of ethnicity, religion, gender or sexual orientation;

- to manage expectations on employment opportunities, by providing information on the level and duration of employment requirements.

12.13.1.3 Optimisation measures

The following optimisation measures will increase the prospects for the employment of and procurement of local goods and services by Turkish nationals, particularly those living in settlements directly affected by construction and residents of Ceyhan and Yumurtalik districts and Adana province. There are six types of optimisation measures, namely:

- those that will optimise local employment opportunities;
- those related to the integrity of the recruitment process;
- measures to deliver skills to employees;
- measures needed to manage public expectations on employment;
- measures for sourcing local goods and services;
- measures for employment during operation.

Optimise local employment opportunities

Contractors will be required to maximise the use of local workers on the project. Priority for unskilled work will be given to settlements directly affected by the marine terminal. Semi-skilled workers to be sourced from Adana Province, where possible. Skilled workers will be sourced from within Turkey. Expatriates will only be used where their particular skills and experience are required.

Opportunities for direct employment will be constrained by the availability of appropriate skills and levels of experience. Taking into consideration the apparent lack of skilled workers in the vicinity of the marine terminal, the focus of the employment strategy will be on the unskilled and semi-skilled workforce. The Project expects that:

- the majority of the unskilled workforce (target of 90%) will come from the settlements directly affected by marine terminal construction;

- a high proportion of the semi-skilled workforce (target of 80%) will come from districts within Adana province;

- a high proportion of the skilled workforce will be Turkish nationals (target of 80%).

Should the Contractor feel that these targets cannot be met, then s/he must provide a thorough explanation and justification, to BOTAŞ, of the reasons why this is not possible.

The Project will agree on an Employment Strategy with the Contractor that will include the expected level of local input for all categories (skilled, semi-skilled and unskilled). This strategy will be written into the agreement of the Contractor and providing levels are acceptable to the Contractor such that financial and contractual limitations are not impaired, performance will be monitored against these targets. This information will be made available to third parties upon request. If these targets are not met, the Contractor will be required to provide justification to the Project.

12.13.1.4 Integrity of recruitment and employment process

The Project will develop an Employment Strategy. This strategy will be discussed and agreed with each Contractor. It will then be publicised and used as a benchmark for recruitment practices throughout the project. All sub-contractors employing more than 50 staff will be required to apply a similar strategy.

The employment strategy will include the following:

- Recruitment Principles explaining how they contribute to the Project Objectives;
- Mechanisms by which preferential recruitment of local workers will be achieved (refer to Box 6.8 in Section 6) for the currently preferred process for recruitment of workers);
- Mechanisms to ensure that the recruitment procedure is transparent and that there is no discrimination;
- Procedures to monitor the compliance of the construction Contractor with employment principles.

The Project will develop an employees' policy to cover employees and contractors involved in the project. This will include commitments to pay and conditions, collective bargaining, working hours, wage levels, maternity leave etc, that is in accordance with Turkish regulations and all relevant international standards (eg International Labour Organisation Conventions). Skills development and an alcohol and drug policy and disciplinary procedures will also be included. The policy shall ensure that wages for local workers are equivalent to what would have been paid to those doing similar work in Turkey and are above the statutory minimum wage.

Information provision

Providing information on employment opportunities and the recruitment process is an essential component of the employment strategy. It is required in order to manage expectations and allow individuals to decide whether they wish to apply for temporary employment. It is also required to ensure that all those eligible have access to the recruitment process.

The Employment Strategy will be distributed to all affected settlements, at least one month prior to the date of recruitment. This will include information on the projected number and duration of employment opportunities, recruitment procedures, pick-up points, the location of recruitment centres and dates of recruitment. This will be done via the following: distribution of leaflets and posters via local representatives (eg the Muhtar or mayor and sub governor);

placing information in public locations (eg bus stops, markets and coffee houses) and distributed orally (eg through the mosque). The Employment Strategy will also be disclosed in local and national media and on the Project web page.

The employment strategy will also be publicised to sub-governors and Muhtars in Ceyhan and Yumurtalik districts, as well as to all sub-governors throughout Adana province. All governors throughout Turkey will be informed. This will help to ensure that the employment strategy for the project is publicised as far a field as possible.

Procurement of local goods and services

As far as possible, the Contractor will source goods from local suppliers both through preferential letting of sub-contracts to local firms (subject to availability and cost) and purchasing of goods from local retailers.

The Contractor will be required to develop a purchasing strategy that outlines the percentage cost of goods to be sourced from suppliers in the districts and province in which the proposed BTC Marine Terminal is located. An outline of the way in which the Contractor will monitor the actual goods and services purchased at the district and provincial level will also be included. Agreed targets for local content will serve as key performance indicators against which the Contractor's performance will be monitored. The purchasing strategy will be required to adhere to all BP HSE policies and procedures.

Advance information on contracting opportunities will be provided to local businesses through trade and industry chambers and local business organisations in Adana Province, particularly Ceyhan and Yumurtalik districts.

Skills enhancement

Induction will be required prior to construction. The Project will carry out training of Contractors on the Project HSE and social policies and on requirements and plans including the SMMP for this project. All workers will have a minimum of five days HSE awareness training. In addition, Site Foremen/supervisors will receive an extra three to five days training on HSE.

The Contractors will be required to develop training strategies for potential employees. Training strategies will include provision for both pre-construction skills training and on-the-job training and identify the contribution that this strategy will make to the local content of employment (directly affected settlements, district, provincial and national levels), and also how it will improve the future employability of workers. The strategy should therefore focus on skills that are transferable, such as language and management skills, or where there is a future market in the local area (eg construction, driving etc).

12.13.1.5 Benefits during operations

The employment strategy for operations will be developed during the construction phase. It will be based on the objective of increasing the proportion of local staff employed in the operating company in line with a long-term view of 100% local operation. Expatriate and non-local staff will be selected for their training and coaching skills as well as their proven HSE and technical expertise.
The employment strategy for operations will be made public through the Project web site and through disclosure in settlements close to permanent facilities.

During operation, it is currently estimated that a total of 200 workers will be employed; of this total, approximately 90% will be skilled and semi-skilled workers and 10% will be unskilled workers.

12.13.1.6 Residual impacts

Expectations regarding employment on the BTC Project are high. The number of people who will gain employment on construction of the BTC Marine Terminal (approximately 400) although substantial, is low when compared to the population of the directly affected settlements and surrounding area. Residents in directly affected settlements who are unsuccessful in their job applications to work on the marine terminal construction, or within the camps, may become frustrated when they do not gain employment. It is also likely that residents of settlements just outside the directly affected project area will be frustrated that they will not get priority access to jobs despite their relative proximity to the proposed BTC Marine Terminal. These unmet expectations could create resentment towards those who succeed in getting jobs, and also towards the Project.

Measures to manage expectations regarding employment opportunities through the disclosure process of the EIA and also a wider communication strategy will help to reduce this potential impact.

12.13.2 Decreased access to fishing grounds

12.13.2.1 Impacts

Overview

The proposed BTC jetty development requires the establishment of a Security Exclusion Zone and a Manoeuvring Area, enforceable for the full life of the project. The exact coordinates and extent of these restricted areas is still being finalised. Any decreased access to marine resources within the restricted areas will, in the absence of mitigation, undermine the ability of fishing households to maintain their existing levels of livelihood.

Studies to assess the impacts of the Security Exclusion Zone and Manoeuvring Area on local fishermen are on-going. The fieldwork for these studies has recently been completed and the results thereof are undergoing final review. Compensation measures still need to be determined and the final results disclosed. The impact assessment results are, however, broadly in line with the conclusions reported in this document.
Causes of the Impacts

Loss of access to fishing grounds is a direct result of the establishment of the Security Exclusion Zone and Manoeuvring Area for the proposed BTC jetty. However, this restricted area is located within a larger 'Area of Operation' for the Toros Gubre Fertilizer Facility, operated by Tekfen Holding. This operating area, declared in 1983, encompasses the northern half of the Iskenderun Gulf and gives Tekfen Holding the sole right to undertake business operations in this area. Within the 'Area of Operation' a small zone is designated around the existing BOTAŞ jetty, referred to as the BOTAŞ Operating Zone (or Ceyhan Port Area)[1], where BOTAŞ holds the operating rights. The new jetty will require the Ceyhan Port Area to be extended in negotiation with Tekfen Holding.

[1] To prevent confusion between the Toros Gubre Operating Area and the BOTAŞ Operating Zone, the latter will be referred to by its other name, the 'Ceyhan Port Area'.

According to the Regulation of BOTAŞ (Ceyhan) Harbour (which designates the 'Area of Operation'), net fishing is not permitted in the following areas: existing BOTAŞ Marine Terminal, BOTAŞ Dortyol facility and Toros Gubre Fertiliser Facility zones. In theory, the extension of the Ceyhan Port Area does not therefore have any implications for net fishing, as the activity is already prohibited within this area. However, the reality is that net fishing (the main fishing method used among local fishermen) occurs regardless of the regulations (except in the Security Exclusion Zone and the Manoeuvring Area for the existing BOTAŞ jetty[1], see Box 12.8 and Box 12.9). Therefore, the establishment of the new BTC Security Exclusion Zone and Manoeuvring Area, where the prohibition on net fishing will be enforced, will bring to an end an activity, within this area, that constitutes an important source of livelihood for local settlements. This assessment therefore considers the impact on existing activities, regardless of legality.

Box 12.8 BTC Security Exclusion Zone

In accordance with Article 20 of Law No. 2565, a Security Exclusion Zone of 400m from the physical borders of the jetty will be proclaimed. This exclusion zone is an essential tool in ensuring the security of the jetty. As such it is considered a high security area falling under the protection of the Turkish Coast Guard. No unauthorised vessels will be permitted in this area.
(Source: BOTAŞ, Ankara office)

Box 12.9 BOTAŞ Manoeuvring Area

The borders of the Manoeuvring Area for the existing BOTAŞ jetty are stipulated in the Regulation of BOTAŞ (Ceyhan) Harbour. In order to ensure the safe manoeuvring of tankers approaching and leaving the jetty, the CMT Port Captains have recommended that the Ceyhan Port Area be increased to encompass a distance of 1.8 km (one nautical mile) from the physical borders of the new jetty. This will require an amendment to the existing port regulation. The Ceyhan Port Area will stretch along the full length of the Golovasi coastline. The following key conditions apply to the Manoeuvring Area:

- Marine traffic (eg local fishing vessels) will be permitted to travel in transit through the Manoeuvring Area. However, when tankers approach the jetty from the direction of Golovasi, all marine traffic will be halted for at least 2 hours.
- In accordance with the Regulation of BOTAŞ (Ceyhan) Harbour, fishing by line and net will be prohibited in the Manoeuvring Area.

(Source: BOTAŞ Ankara office and existing Marine Terminal)

Direct impacts

Understanding the impacts of decreased access to marine resources requires an assessment of the following:

- the relationship between the location of the Security Exclusion Zone and Manoeuvring Area and the fishing grounds used by local residents;

[1] In the Manoeuvring Area (for the existing BOTAŞ MarineTerminal), line fishing is currently being allowed as it poses less of a safety risk than the nets, which are harder to move out of the way in the event of a tanker arriving or an unexpected emergency.

- the importance of the impacted fishing grounds for the settlement/s concerned (ie frequency with which they are used and type and extent of marine resources found within the fishing ground/s);

- the extent to which fishing contributes to livelihoods on the household, as well as the role it plays as a 'way of life'.

Discussion of these issues is based solely on information gathered from local fishermen. As such, the findings outlined below are considered to be preliminary, and will be revised on completion of the additional studies currently underway.

Loss of Fishing Grounds Due to the Security Exclusion Zone and Manoeuvring Area: the fishing grounds in the Study Area can be divided into four main zones (as defined by fishermen from Golovasi, Sahil Sitesi and Incirli):

- **Zone 1:** between the Sugozu Thermal Power Plant and the existing BOTAŞ jetty exclusion zone (approximately 4.5km along the coast and up to 1km offshore from Golovasi). Used primarily by fishermen from Golovasi and Sahil Sitesi.

- **Zone 2:** between the existing BOTAŞ jetty exclusion zone and the Sugozu Thermal Power Plant (approximately 4.5km along the coast and from 1km to 3.5km offshore. Used primarily by fishermen from Golovasi and Sahil Sitesi.

- **Zone 3:** between the Toros Gubre Fertiliser Facility jetty exclusion zone and the existing BOTAŞ jetty exclusion zone (approximately 1km along the coast and up to 3.5km offshore). Used primarily by fishermen from Incirli and Karatepe.

- **Zone 4:** over 3.5km offshore and is used primarily by non-local fishermen.

A map illustrating the zones identified by local fishermen as the main fishing grounds is provided in Section 10, Figure 10.29.

The restricted areas (see Box 12.10) associated with the new jetty will impact on Zones 1 and 2, both of which are used almost solely by fishermen from Golovasi and Sahil Sitesi.

Box 12.10 Establishment of Restricted Areas: Feedback from Local Residents

During consultation, the fishermen expressed concerns about the impact of new restricted areas on their fishing activities. Based on experiences of the Security Exclusion Zone for the existing BOTAŞ Terminal, one fisherman stated that *"the Ceyhan Marine Terminal exclusion zone makes net fishing impossible … if another jetty is established here, the fishing will die"*.
(Source: Fishermen from Incirli and Golovasi)

Value of Impacted Fishing Grounds: the value of the impacted fishing grounds for Golovasi and Sahil Sitesi is reported to be high. This is linked to the following factors, as defined by local fishermen:

- Zones 1 and 2 are used solely by fishermen from Golovasi and Sahil Sitesi. This is based, in part, on an informal agreement with fishermen from Incirli that both settlements will fish predominantly in areas off their own coast. Fishermen from Incirli and Karatepe therefore fish mostly in Zone 3 (See Figure 10.22). Zone 4 is too deep for fishing with the nets used by local fishermen.

- Zone 2 is the most important fishing ground for Golovasi/Sahil Sitesi. It is here that they catch shrimp (*karides*), which have higher market value than other marine species[1]. Shrimp are also a localised species, thus adding to the value of Zone 2. *Lahos*, the most expensive type of fish, was only reported to be caught by fishermen from Golovasi/Sahil Sitesi, although it is not clear whether they are caught in Zone 1 or 2. Although shrimp are also caught in Zone 3, the sizes of the catches are reported to be much lower in this area.

- Zone 1 is the second most important fishing ground for Golovasi and Sahil Sitesi as it is here that fish can be caught all year round, even though the fish caught are not as valuable as the shrimp caught in Zone 2.

- Zone 1 and 2 offer the advantage of being much closer to Golovasi/Sahil Sitesi than Zone 3. This saves on fuel costs and enables the fishermen to throw their nets in the early evening (between 17h00 and 19h00), returning home for the night, and collecting their nets the following morning (between 7h00 and 10h00).

In summary, Zone 1 and 2 are of high value to the fishermen from Golovasi and Sahil Sitesi, both in terms of their respective resources, their nearby location and the near-exclusive use that they have of these fishing grounds. Based on information currently available, a reduction of the total area of Zone 1 and 2 is therefore considered significant in terms of the potential impact on livelihoods.

Implications for Securing a Living: according to local authorities and fishermen, the Iskenderun Gulf has experienced a decrease in fish stock since the early 1980s, due to increased environmental pollution, trawling and over fishing. Although the current fish stock is reported to be low, people still depend heavily on fishing as a main source of income. This is due, in part, to limited alternative forms of livelihood and the role fishing plays as a 'way of life'. Thus, in spite of decreased stock and the impact this has on fishing as a viable form of livelihood, the loss of fishing grounds in Zones 1 and 2 are likely to result in the following:

- **Decreased percentage contribution of fishing to household income:** fishing was reported as a main source of livelihood (subsistence and income-based) for 10 of the 26 households surveyed in Golovasi. Alternative sources of livelihood are limited within the project area due to limited and unevenly distributed agricultural land, decreased agricultural productivity and limited wage income opportunities.

- **Decreased ability to pay back debt owed:** high levels of debt were consistently reported among fishermen. This is understood to be a result of high equipment and fuel costs. As a result, profit margins from fishing are low. Already, decreased sources of livelihoods and the inability of the household head to care for the family is being linked to an increase in depression and alcoholism in the Study Area (as reported in the settlement and household surveys).

- **Increased fuel costs:** diminished fishing grounds are likely to force fishermen from Golovasi and Sahil Sitesi to travel further a field in search of alternative fishing grounds. This will result in increased fuel costs. In the context of high debt levels and low profit margins, the increased fuel costs may contribute to a loss of income earned from fishing, thus potentially impacting on levels of livelihood within the household.

[1] There is a river inlet at Golovasi which increases nutrient levels near the river mouth, creating a better environment for shrimp production. The fishing grounds off Golovasi are also considered to be less polluted than Incirli, where local residents complained about the environmental impacts of the Toros Gubre fertilizer facility.

Box 12.11 Impact on Livelihoods: Feedback from Local Residents

During consultation fishermen expressed concern about not being able to fish as a result of the proposed Security Exclusion Zone and Manoeuvring Area and how this would prevent them from meeting their families' needs. In the words of one fisherman *"how will we be able to look into the face of our children if we cannot feed them?"*

"Even though we do not profit much from fishing we still have the hope that the sea will continue to feed us. Even if we catch one or two fish a day we can give food to our children. This is not possible from any other place".
(Source: Fishermen from Golovasi)

Implications for Way of Life: for many of the villagers, fishing is a 'way of life' not only a source of income. For many families, fishing has been a family business for generations. Fishing is an activity in which the whole family is often involved (women and adolescents fix and clean nets). Loss of fishing as a form of livelihood could undermine cohesion of the family as a working unit. Furthermore, each boat has, on average, 3-4 fishermen from different households. This allows for a sense of community and helps establish relationships and support networks essential for survival among poorer settlements.

Box 12.12 Impact on Way of Life: Feedback from Local Residents

"We have grown up on boats and have been on the sea since childhood. Fishing allows us to have a different lifestyle to those that are occupied by agriculture."

"Sea is love to me; I am addicted to it; I cannot live on the land."

(Source: Fishermen from Golovasi)

Suitability of Available Fishing Alternatives

Formulating appropriate mitigation requires consideration of a range of options and an analysis of their suitability. Table 12.7 provides a summary of two options, including key constraints that need to be taken into account in the development of mitigation measures.

Table 12.7 Development of Mitigation Measures

Option A: USE OF ALTERNATIVE FISHING GROUNDS WITHIN 5 NAUTICAL MILES OF THE PROJECT AREA	
KEY CONSTRAINTS	• Size of catches reported to be lower in Zone 3 due to pollution from existing developments (eg Toros Gubre Fertilizer Facility) and lack of river inlet encouraging breeding of shrimp. • Gentleman's agreement with fishermen in Incirli that settlements will focus on fishing grounds closest to their stretch of coast. • Increased fuel costs due to diversion around existing and proposed jetty on route to Zone 3 or further up the coast. • Increased time required to travel to alternative fishing grounds. Preliminary findings suggest that the fishing boats are able to travel, on average, 3.5km per hour. • Boats do not have cabins for over-night purposes. As a result, fishermen need to return home for the night (after throwing nets) and return in early morning to bring in the catch. • There are reportedly a high number of fishermen already fishing off the coast of Yumurtalik (eg fishermen from Haylazli, Deveciusagi and Yumurtalik).
Option B: TRAVEL FURTHER AFIELD, BOTH OFF-SHORE AND/OR FURTHER UP OR DOWN THE COAST	
KEY CONSTRAINTS	• Boats are small and not considered sufficiently sea-worthy or powerful to travel long distances. • Fishermen do not have the necessary equipment for fishing in deeper seas. Nets used by the local fishermen cannot be used in deep seas. • Fishermen are concerned about travelling further a field in case of bad weather and due to the lack of docking facilities (for security reasons, boats are prohibited from docking at the BOTAŞ and Toros Gubre jetties, regardless of weather conditions. The same is likely to apply for other jetties in the Iskenderun Gulf). • Increased fuel costs associated with travelling further a field. • Boats do not have cabins for over-nighting purposes, thus limiting the distance they can travel. • Fishing grounds of Sarigol, Adalar, Arap bogazi and Dalyan (south-west of Yumurtalik) already utilised by Haylazli and Deveciusagi.

12.13.2.2 Impact summary

Direct impacts

Diminished access to marine resources as a result of the establishment of the Security Exclusion Zone and the Manoeuvring Area is considered to be certain, although the extent of this impact is yet to be confirmed. These impacts will mostly affect fishermen in Golovasi and Sahil Sitesi, although a decrease in their fishing grounds may force them to fish in Zone 3 (in spite of the gentlemen's agreement with Incirli and Karatepe), thus putting pressure on the livelihoods of other fishermen[1]. Decreased access to marine resources, as a result of the BTC Jetty, is considered to be *long-term*.

Impacts on livelihood assets

An assessment of the livelihood assets within Golovasi and Sahil Sitesi, shows that decreased access to marine resources will result in a loss of the following types of assets:

[1] The occurrence of this impact depends on the extent to which fish in Zones 1 and 2 are localised species and therefore likely/unlikely to inhabit other fishing grounds. Shrimp, as a localised species, will be put under additional pressure in Zone 3, if the fishermen from Golovasi/Sahil Sitesi fish increasingly in this area.

- **Natural capital:** although marine resources could increase as a result of the breeding refuges created, access to resources within the existing fishing grounds will be decreased. In the absence of suitable alternatives (eg use of other fishing grounds with equivalent resources), this will result in a loss of natural capital.

- **Financial capital:** decreases in the size of daily catches will impact on revenue earned.

- **Social capital:** loss of earnings and decreased access to a subsistence livelihood has the potential to result in: 1) decreased social cohesion at the household level (as a result of increased pressure to secure a living and potential increases in depression and alcoholism); and 2) decreased social cohesion on the settlement level (as a result of increased conflict over scarce resources, and changes to distribution of wealth within the settlement, with associated changes to existing power structures).

- **Human capital:** a deterioration in health as a result of emotional stress (possibly including depression and alcoholism) and decreased levels of nutrition (in the absence of disposable income for food provision and possibly decreased fish for consumption).

In the absence of appropriate mitigation, a loss of capital assets will occur, resulting in a reduction in the current levels of livelihood for fishermen in Golovasi and Sahil Sitesi. Based on information currently available, households can be divided into two groups according to their ability to adapt to this change.

- Ability to adapt is predicted to be *very low* for fishermen/households where fishing is their main or sole source of income, for poorer households (with less savings and higher debt levels), for older fishermen (who are less able to pursue alternative livelihood options) and for fishermen lacking transferable or alternative skills.

- Ability to adapt is predicted to be *low to medium* for fishermen/households for whom fishing is a secondary source of employment, who have accumulated savings as a financial buffer, who are younger and therefore more able to start anew or who have transferable or alternative skills. The current lack of alternative sources of livelihood is a crucial factor in this rating.

12.13.2.3 Significance criteria

A decrease in access to marine resources will be considered significant if the proposed mitigation measures are insufficient to maintain the original standards of living of the affected households[1].

12.13.2.4 Mitigation objectives

The Project has committed themselves to the following mitigation objectives:

- To ensure that appropriate compensation is provided to fisherman affected by the establishment of the Security Exclusion Zone and Manoeuvring Area, as determined in the land acquisition process;

[11] Following completion of the additional studies, appropriate methods and targets for monitoring standards of living will be developed. These will take consideration of other factors contributing to decreasing fish stock, and ensure that monitoring activities address BTC related issues.

- To ensure continued access to port facilities;
- To prioritise local residents for employment opportunities, subject to availability of appropriate skills.

12.13.2.5 Mitigation measures

The following mitigation measures have been developed to meet these objectives:

Compensation Strategy

A procedure for compensation will be developed and targeted at registered fishermen who incur a loss of livelihood as a result of the construction and operation of the BTC Marine Terminal.

Continued Port Access

The Project will maintain access to the Golovasi Port throughout construction and operation.

Employment Strategy

Contractors will be required to maximise the use of local workforce on the project. Settlements directly affected by the marine terminal will take priority, followed by workers in Ceyhan and Yumurtalik districts and then Adana province.

Training Strategy

Contractors will also be required to develop a training strategy for potential employees, thereby maximising the opportunities for employment of local residents.

12.13.2.6 Residual impacts

The successful implementation of the above mitigation measures will assist in minimising the impact of the Security Exclusion Zone and the Manoeuvring Area. In keeping with World Bank requirements, the land acquisition process will include procedures for internal and external monitoring, as well as measures for addressing any feedback received.

12.13.3 Tourism

12.13.3.1 Impacts

Although tourism is not a major economic activity in the project area[1], there are households that do rely on it as a source of income, notably in the settlements of Golovasi, Sahil Sitesi, Incirli, Sugozu and Hamzali. There are also recreational facilities at the existing BOTAŞ terminal[2], although these are only accessible to BOTAŞ employees, their families and guests.

Factors that could affect the suitability of the project area for tourism activities include visual impacts of the marine terminal, including tanker traffic (operation phase), minor noise impacts (construction phase), and increased industrialisation in the project area (permanent).

[1] Only 8% of the total households surveyed identified tourism is a source of income.

[2] These facilities include a private beach, a guesthouse with approximately 50 rooms and a restaurant.

These predicted impacts (with the exception of increased industrialisation) are likely to affect the settlements of Incirli, Golovasi, and Sahil Sitesi and the BOTAŞ tourist facilities. However, both Incirli and the BOTAŞ tourist facilities are located within an existing industrial context, with tourism continuing regardless. As a result, the development of the marine terminal is not expected to impact on tourism in these two areas. Incirli will also be shielded from the new jetty by the existing offshore facilities.

Although a similar continuation of tourism could be predicted for Sahil Sitesi, this area is currently secluded, quiet and relatively unspoilt, in spite of a view of the existing jetty less than 3km away. This reportedly has attracted a high number of secondary homeowners (approximately 150) who have built holiday houses in Sahil Sitesi, and who use the location as a retirement and holiday retreat (see Plate 12.9).

In terms of visual impacts, Sahil Sitesi has been identified as the only settlement likely to experience major visual intrusion from the marine terminal development. The concern therefore exists that the visual impact will make the area less desirable as a tourist destination and reduce the number of tourists and amount of revenue generated.

Factors mitigating this concern include the following:

- the small proportion of surveyed households that identified tourism as a source of income (only one household in Sahil Sitesi and four in Golovasi) (this includes fishermen who occasionally earn money by taking tourists on boat-rides).

- a limited number of tourist facilities that stand to be impacted upon (two restaurants on the beachfront, both in the process of being completed, and a restaurant and small camping ground in Golovasi) (see Plate 12.10 and Plate 12.11).

- although an annual estimate of between 600-1,500 visitors come to Golovasi and Sahil Sitesi, including secondary home owners, there is a possibility that the increased industrialisation will not deter them.

In spite of these mitigating factors, the possibility exists that, as a result of the construction of the new jetty, secondary homeowners will not frequent Sahil Sitesi for as long or as frequently as they currently do[1]. This could have implications for revenue spent in Sahil Sitesi and Golovasi. However, increased industrialisation in the area will increase the size of the clientele for restaurants and local retailers, thereby compensating for the potential decrease in tourist and secondary homeowner trade. Furthermore, with the construction camp currently located within BOTAŞ property and therefore within commuting distance of Sahil Sitesi, the construction workers could also add to revenue spent in this settlement, although this would need to be in agreement with local residents[2]. Revenue from construction workers would, however, be a short-term benefit.

12.13.3.2 Impact summary

There will *definitely* be a permanent change to Sahil Sitesi as a result of the visual impacts associated with the proposed BTC Marine Terminal and increased industrialisation in the broader project area. The extent to which this will negatively affect tourist activities is currently unknown. However, using Incirli as a precedent (where tourism has continued in

[1] Results of the survey indicate that secondary homeowners come to Sahil Sitesi weekly or monthly, most commonly in summer between June and September.

[2] In the event that local residents agree to construction workers having access to local retail services, the behaviour of construction workers will need to be monitored by the community relations officers in order to ensure compliance with the stipulated Codes of Conduct for construction workers (see Section 12.8.2.4).

spite of adjacent industrial development), it is likely that tourism in Sahil Sitesi will carry on regardless. Should tourism and/or numbers of secondary homeowners decrease, this will only affect a very small proportion of households in Sahil Sitesi and local retailers in Golovasi. Increased industrialisation is, however, likely to bring additional clientele to the area, thus assisting households dependent on the tourist trade to adapt to this change.

12.13.3.3 Significance criteria

Impacts on tourist activities will be considered significant if there is a dramatic reduction in tourism activities following the construction of the proposed BTC Marine Terminal. The significance of any reduction will however, be assessed against the ability of these households to secure alternative forms of livelihood.

12.13.3.4 Mitigation objectives

In order to minimise any potential impacts on tourism activities, the Project has committed to minimising noise levels to legally acceptable standards, as presented in Section 12.7. No measures exist for mitigating the visual impacts associated with the jetty.

12.13.3.5 Mitigation measures

Specific measures that will be carried out regarding noise levels are included in Section 12.7.

The Projects Participants have also committed to a number of mitigation measures that enhance the procurement of benefits by local residents. These measures will assist in ensuring that local residents are compensated for any loss in tourism revenue. These measures include the following:

Employment strategy

Contractors will be required to maximise the use of local workers on the project. Settlements directly affected by the marine terminal will have priority, followed by workers in Ceyhan and Yumurtalik district and then Adana province.

Training strategy

The Contractor will also be required to develop a training strategy for potential employees, thereby maximising the opportunities for employment of local residents.

12.13.3.6 Residual impact

No residual impacts are expected.

12.14 INFRASTRUCTURE AND SERVICES

12.14.1 Impacts

This section addresses impacts to infrastructure and services as a result of the construction of the on-shore and offshore facilities, including the construction of the pipeline through BOTAŞ property. The main focus is on utilities (telephone, energy, water and sewage treatment) and access to services. Traffic and waste are dealt with in the TMP and WMP. Impacts on infrastructure and services, as a result of in-migration to the project area, are discussed in Section 12.8.3.

12.14.1.1 Utilities

Project plans can be summarised as follows:

- **Telephone:** during construction the project will use both landline and mobile networks. During operation, the project will be largely self-sufficient.

- **Energy:** energy requirements during construction will be relatively limited and will not impact on local settlement needs. Energy requirements will be sourced from the existing terminal supply. If surplus capacity is not available, the Project will apply for an extension to the supply serving the existing BOTAŞ Marine Terminal through the relevant authorities or use mobile generators.

- **Water supplies:** water requirements for the BTC Terminal will be supplied from a well, located approximately 20km east of the existing BOTAŞ Marine Terminal. Water will be transported via a 6-8 inch water pipe to the BOTAŞ property. An additional well and pipeline to transport water to the BOTAŞ property is currently under consideration. The main requirements for water will be for hydrostatic testing of the tanks and pipeline. Additional water will be required for the construction camp and construction site.

- **Sewage Treatment:** a domestic sewage treatment system is currently utilised by the existing BOTAŞ Marine Terminal. This system has spare capacity and will therefore be used to service the construction camp within the BOTAŞ property. In the event that existing capacity is exceeded, separate sewage treatment package units will be used, thus ensuring that the project is self-sufficient.

- **Waste:** waste management arrangements and provisions will be prepared by the Construction Contractor in compliance with the BTC Project Waste Management Plan (See Appendix C3).

Potential impacts of the use of utilities during construction are the following:

- An overload of the existing service in particular for water supply and electricity (impacting on regularity of electricity supply).

- Accidental or planned disruption to utilities during construction.

- Potential for ‘spin-off’ benefits to local settlements from infrastructure required by the project.

12.14.1.2 Services

There will be no direct impacts on the education services, as all construction workers will be employed on a single status basis. The construction camp will also have its own health facilities and will not use the health services of the local settlements. Nevertheless, there are potential impacts associated with health provision and the perception of health provision by the local residents. These include the following:

- a strain on community relations close to construction camps due to the superior health provision provided to the construction workforce;
- diseases brought to the area by construction workers;
- blocked roads (as a result of traffic congestion) preventing access to health care or extended time to reach health care.

The first two of these impacts have been considered under community relations (see Section 12.8.1).

12.14.2 Significance criteria

Infrastructure and services have been identified as being of poor quality by the local residents: the telecommunications network is underdeveloped, electricity and water supply is irregular, and sewerage and waste facilities have limited coverage.

Given these factors, impacts on infrastructure and services are considered to be significant if:

- there is a permanent loss or improvement in the quality of the infrastructure or services that are used by local residents;
- there is a temporary disruption in infrastructure or services that impacts adversely on the ability of local residents to undertake subsistence or economic activities;
- there is a temporary or permanent change in access to emergency services.

Significance criteria used during the assessment are provided in Table 12.8. As for all aspects of the environment, mitigation was developed with the objective of preventing all significant impacts.

Table 12.8 Criteria for Identifying Significant Impacts on Infrastructure and Services

Infrastructure / Services	Significance Criteria
Roads	• Closure of roads that prevent public transport services from continuing. • Diversion of more than 500m for pedestrians or livestock.
Transport	• See TMP (Appendix C5).
Utilities (including telecommunications, water supply, sewerage, electricity)	• Any reduction in the quality of the services without three days prior notice. • Any planned reduction in the services for more than 12 hours without appropriate alternatives where risk assessment has shown this to be detrimental to health or livelihoods.
Emergency services	• Any reduction in the quality or access of the services, including time to hospitals.
Benefits	• Improvement to infrastructure or services, either temporary or permanent.

12.14.3 Mitigation objectives

The Project has committed to the following mitigation objectives:

- 'No permanent net loss' of infrastructure and services to local settlements;
- No significant temporary impacts on infrastructure or services;
- No reduction in services available to local settlements due to the use of that service by the Project.

The Project will seek opportunities for settlements to mutually benefit from the activities undertaken, and infrastructure required, by the Project.

12.14.4 Mitigation measures

12.14.4.1 General mitigation measures

The majority of the measures to be implemented are the responsibility of the Contractor. As such, detailed requirements will be included in the agreement of the Contractor. The Contractor will be required to incorporate them into their management plans and ensure that they are included in any sub-contracts. These requirements, plus additional mitigation measures that are the responsibility of the Project, are identified in this section.

The mitigation strategy is fundamentally the same for all types of infrastructure and services.

To minimise disruption to infrastructure and services, the Project will:

- use appropriate construction techniques, examples of which have been identified in Section 9. Although the contractors will be able to suggest alternate or additional measures, they will be required to demonstrate that these measures will achieve the mitigation objectives as efficiently as those specified in this EIA;

- work within specified working areas. These will be determined prior to construction and demarcated using fencing, marker posts or signs for roads. Any failure to stay within the terminal site and temporary construction areas will be a serious disciplinary offence that may result in termination of employment.

To avoid significant temporary impacts on infrastructure or services the project will:

- identify potential disruption in advance;

- where the planned disruption will last beyond 12 hours the Project will carry out a risk assessment in consultation with the affected settlements and appropriate authorities to identify the impacts that this disruption would cause. Where the risk assessment shows that there will be a risk to health or impact on livelihood of affected settlements, appropriate alternatives will be put in place, or the job will be re-planned;

- communicate the timing and duration of any disruption to infrastructure to settlements at least three days ahead of the disruption (see Section 10.10.2).

Should infrastructure or services be disrupted without warning, the Project will:

- wherever possible, inform the authorities of the affected settlements within two hours of the disruption occurring, providing the reason for the disruption and the expected duration of the disruption. Within one day, written information will be provided to the settlement Muhtar/s (or mayors of the district centres) providing details of the disruption, of measures already taken and any additional measures that will be taken to assess the damage caused as a result of the disruption. The CLO will ensure that there is an announcement in the mosque and that notices are posted on the settlement notice board, such that the local residents are informed of the disruption;

- ensure that it has the resources to respond to any such disruption within time periods that will not result in damage to the health or safety of those affected.

To avoid any net loss of infrastructure or services, the Contractor will:

- undertake a pre-condition survey to assess the existing condition of the working area (including local roads used by construction traffic). Photographs will be taken as a record of condition. Local authorities will be requested to verify these photographs and be provided with copies;

- agree a timetable of any planned disruption with the authorities and local residents. Should the disruption be judged by the affected party to result in a loss in livelihood, the validity of the claim and necessary compensation will be determined;

- where possible, immediately repair any damage to infrastructure caused by the construction. Such work will not cease until the infrastructure has been repaired to its pre-construction condition. All such restorations will be completed within two months of completing substantive work in that area. Should this timescale be expected to be exceeded, a plan for the work will be prepared and presented to the affected settlements and local authorities;

- resolve all complaints from settlements regarding interruption to infrastructure or access to resources within seven days. Where this is not possible, a response plan will be agreed with local settlements within this timeframe;

- inspect all restoration measures after completion of the works and periodically during the lifetime of the project. Any deterioration related to inadequacy of construction and restoration activities over the first year will be restored by the Contractor.

To avoid any net loss of infrastructure or services, the Project will:

- monitor the compliance of the Contractor with the above measures;
- hold post-construction community meetings to discuss any residual problems.

Specific additional measures for mitigation of impacts on particular infrastructure and services are identified in the following sections.

12.14.4.2 Additional mitigation measures for utility services

- The Project will hold discussions with the utility service providers to identify if the use of the services by the project will result in a reduction in service received by local settlements.

- In cases where utilities need to be disrupted for less than 12 hours the CLO will inform the leaders of local settlements within 2km of operations, ensure that there is an announcement in the mosque and that notices are posted on the community notice board at least three days in advance of disruption.

- Where deliberate disruption to utility services (telephone, electricity, water) for more than 12 hours is required, the Project or the Contractors will liase with the responsible Authorities/Suppliers to provide alternative supplies. Where alternative supplies cannot be provided, a risk assessment will be carried out including assessment of the impact that a disruption to services will have on the livelihood of local residents. This will require consultation with the affected settlements. Where the risk assessment demonstrates either an impact on livelihoods, or where the disruption is not acceptable to local residents, the job will be re-planned.

- Subject to the full and effective implementation and maintenance of the BTC Project's Waste Management Plan, the implication for existing waste management and disposal facilities will be fully considered in the finalisation of the Contractor's waste management arrangements.

12.14.4.3 Potential benefits: infrastructure spin-offs

The Project is likely to require the construction of new infrastructure and may require the enhancement of some existing infrastructure. There are examples where projects have successfully managed to work together with government, civil society and local residents in order to pool skills and resources so as to achieve sustainable benefits for local residents. For the marine terminal, areas where these 'spin-offs' may be realised include the following.

- **Water:** boreholes may be required to provide water to the construction camp. Such systems may be able to be left or extended to benefit local residents.

- **Roads:** upgrades of local roads may be required to facilitate increased traffic to the marine terminal during construction.

- **Schools:** facilities and resources at local schools may be increased to accommodate the children of foreign, skilled workers. This may result in opportunities for more local pupils to attend.

- **Health Facilities:** the Contractor will be prepared, at the request of the Project, to hand over camp medical facilities to neighbouring settlements at the closure of the camp.

In these cases, enhancements will, where possible, be linked into existing infrastructure plans in order to contribute to long-term enhancement of the infrastructure in the project area. Where these enhancements are beyond project requirements, the Project will look to partner with other agencies to share the costs and to ensure that the infrastructure will be appropriately maintained such that benefits are maximised over the long term.

Prior to construction, the Project will develop a strategy for taking such opportunities forward where possible.

12.14.5 Residual impacts

The mitigation measures identified above, implemented correctly and in full, will minimise the majority of significant impacts on infrastructure and services. However, in a project of this

size there may be instances when infrastructure and services are disrupted without notice and prior planning. Where such disruptions affect income generation (subsistence and income-based), this will need to be dealt with through the compensation and Complaints Procedure.

Significant additional benefits for local residents may be able to be realised by the Project should they be successful in linking project infrastructure needs into existing infrastructure plans.

9 THE MARINE TERMINAL

9.1 INTRODUCTION

The proposed BTC Pipeline will culminate in a crude oil storage and export terminal (the BTC Marine Terminal) which is to be located near Ceyhan on the Gulf of Iskenderun on the coast of the Mediterranean Sea (see Figure 9.1). The proposed terminal and associated facilities will comprise an integral part of the BTC Pipeline Project.

Owing to the complexity of the proposed BTC Pipeline Project, this EIA Report addresses the proposed Pipeline (Volume II) and Marine Terminal (Volume III) separately before presenting the overall findings of the integrated BTC Pipeline Project (Volume IV). This section of the Report describes the proposed BTC Marine Terminal and associated facilities. The proposed BTC Pipeline is described in Section 4. An effort has been made to assist the reader by presenting all pertinent information regarding the Marine Terminal and associated facilities within this section of the Report. However, the design, construction and operation of the Terminal is inextricably linked to that of the Pipeline, which has been comprehensively described in Section 4. In order to minimise extensive repetition, this section makes reference to the appropriate subsection of Section 4 when the subject matter is deemed to have been adequately covered in that section.

In the course of basic and detailed design, a number of strategic and design options have been considered for the BTC Marine Terminal. This has included alternative site locations, process configurations, emissions control and sources of raw water. The principal alternative options are discussed in Section 2. This section of the Report describes only the finally chosen concept (except where significant design options remain to be made, in which case this is identified).

9.2 GEOGRAPHICAL CONTEXT

The proposed BTC Marine Terminal is to be located on the north-eastern shores of the Gulf of Iskenderun (36°:53':00" north and 35°:56':06" east). It will be sited adjacent to the Iraq-Turkey Pipeline (ITP) Marine Export Terminal (hereafter referred to as the Existing BOTAŞ Marine Terminal).

The various components of the marine terminal will occupy a total area of approximately 135 ha. The elevation of the terminal complex site ranges from approximately 125m to 7m above sea level. This difference in height is a key feature of the site, as it will enable oil to be gravity fed from the oil storage tanks downhill to the export jetty.

9.3 SCHEDULE FOR PROJECT DEVELOPMENT

The main mobilisation will commence in Autumn 2002 with groundbreaking commencing in late December 2002. Construction of the BTC Marine Terminal is scheduled to last approximately 20 months. Commissioning is scheduled to commence in October 2004 with normal operation scheduled to commence in February 2005. The schedule for the sequencing of the remaining project activities is presented in Figure 9.2.

Figure 9.1 The Location for the BTC Marine Terminal at Ceyhan

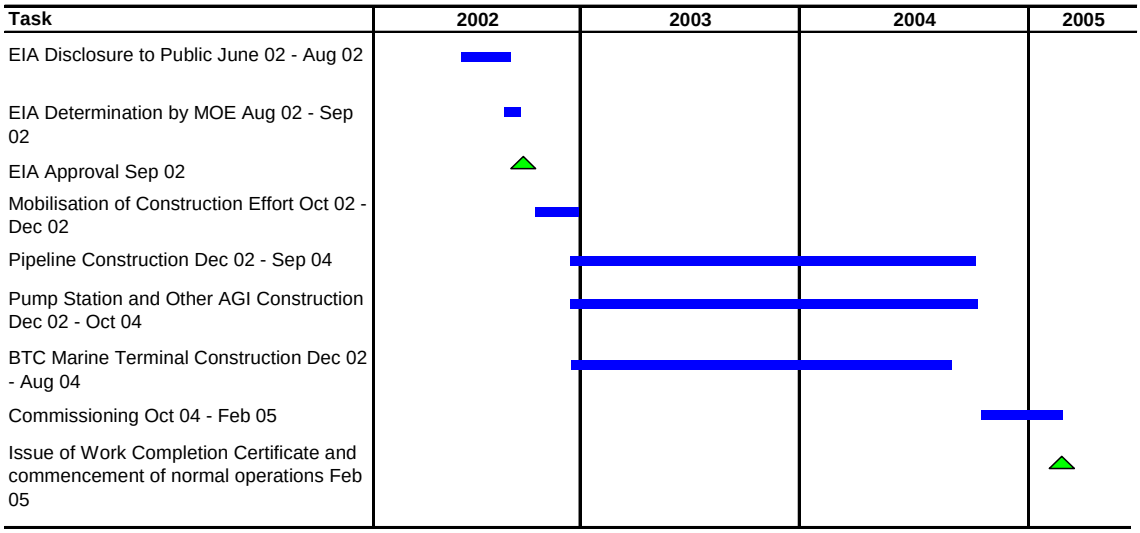

Figure 9.2 Anticipated Schedule to Project Completion

It is anticipated that the BTC Marine Terminal and its associated facilities will have a lifetime of approximately 40 years and that they will be decommissioned thereafter in accordance with international standards in place at that time (see Section 9.8).

9.4 DESCRIPTION OF THE BTC MARINE TERMINAL

9.4.1 Facilities overview

An overview of the overall BTC Pipeline Project is presented in Section 4 of this report. The BTC Marine Terminal essentially comprises two sets of facilities:

- Ceyhan Export Terminal, comprising seven 150 800m^3 crude oil storage tanks plus associated receiving facilities, loading lines, administration and control buildings.

- Ceyhan Marine Facilities, comprising a fiscal metering station, a jetty capable of berthing two 300 000 DWT tankers simultaneously and facilities for loading oil on to the tanker.

An aerial view of the overall layout of the BTC Marine Terminal and proposed facilities in relation to their immediate surroundings is presented in Figure 9.3. A schematic of the principal terminal activities is depicted in Figure 9.4.

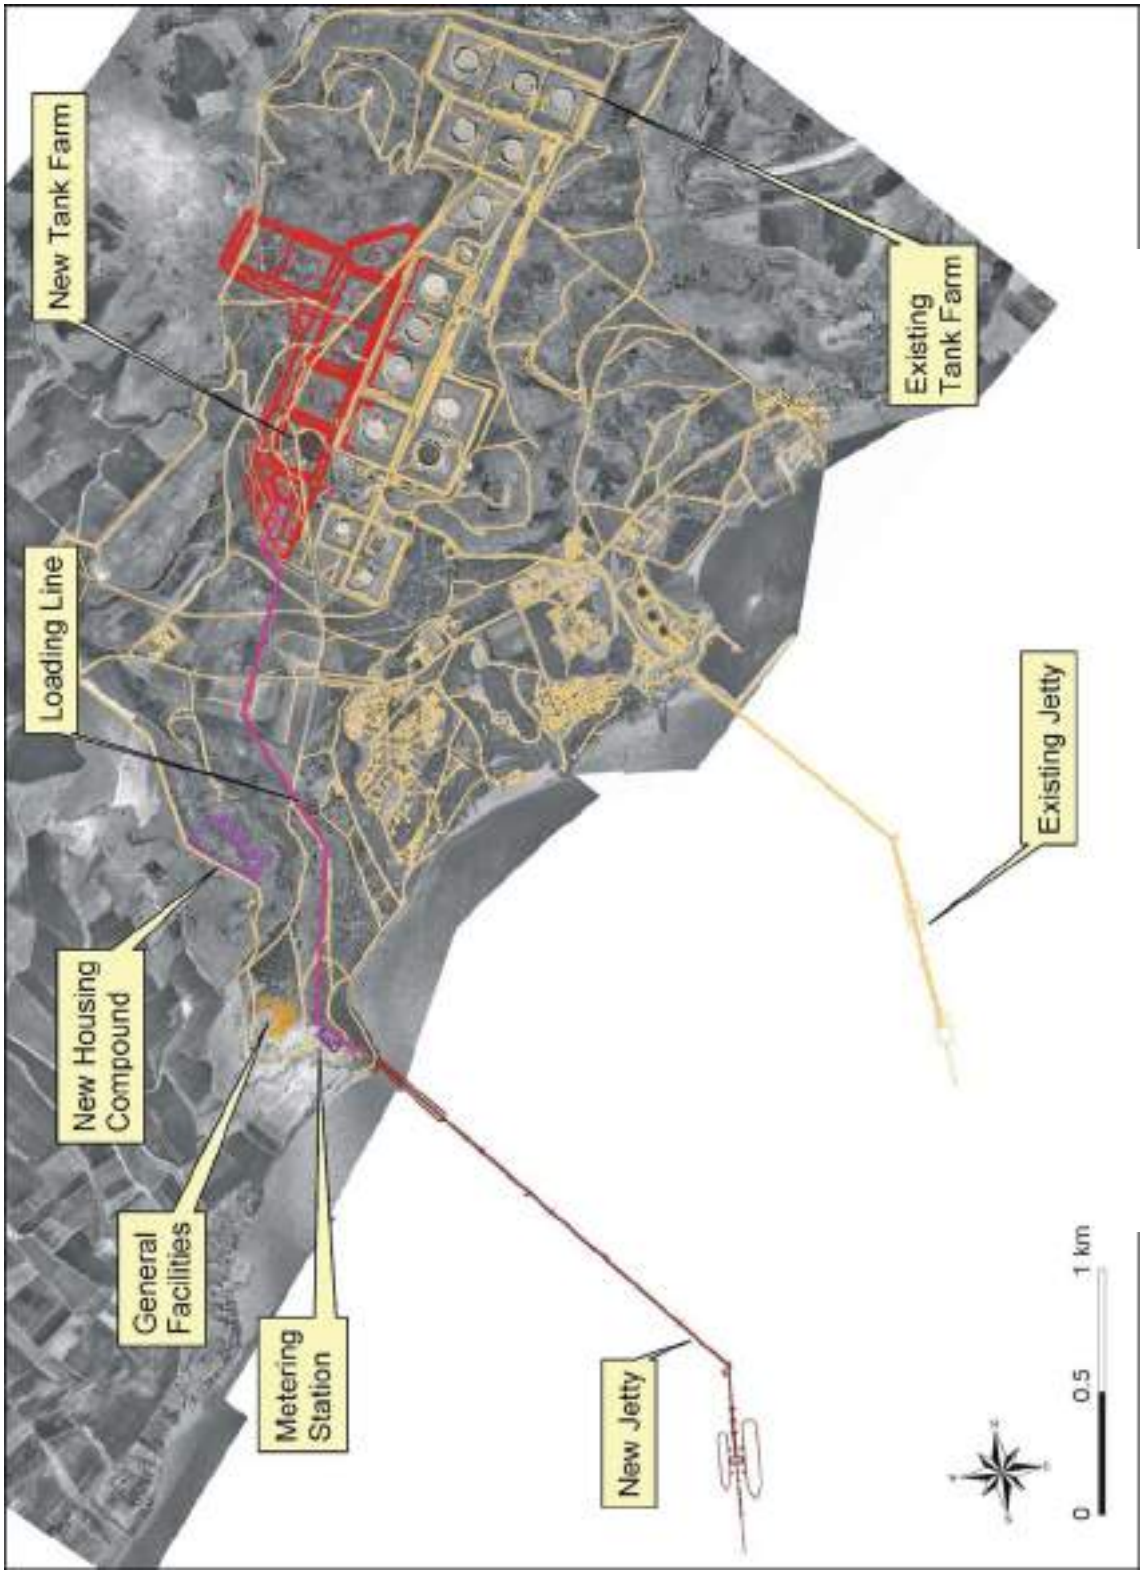

Figure 9.3 Aerial view of the BTC Marine Terminal Site

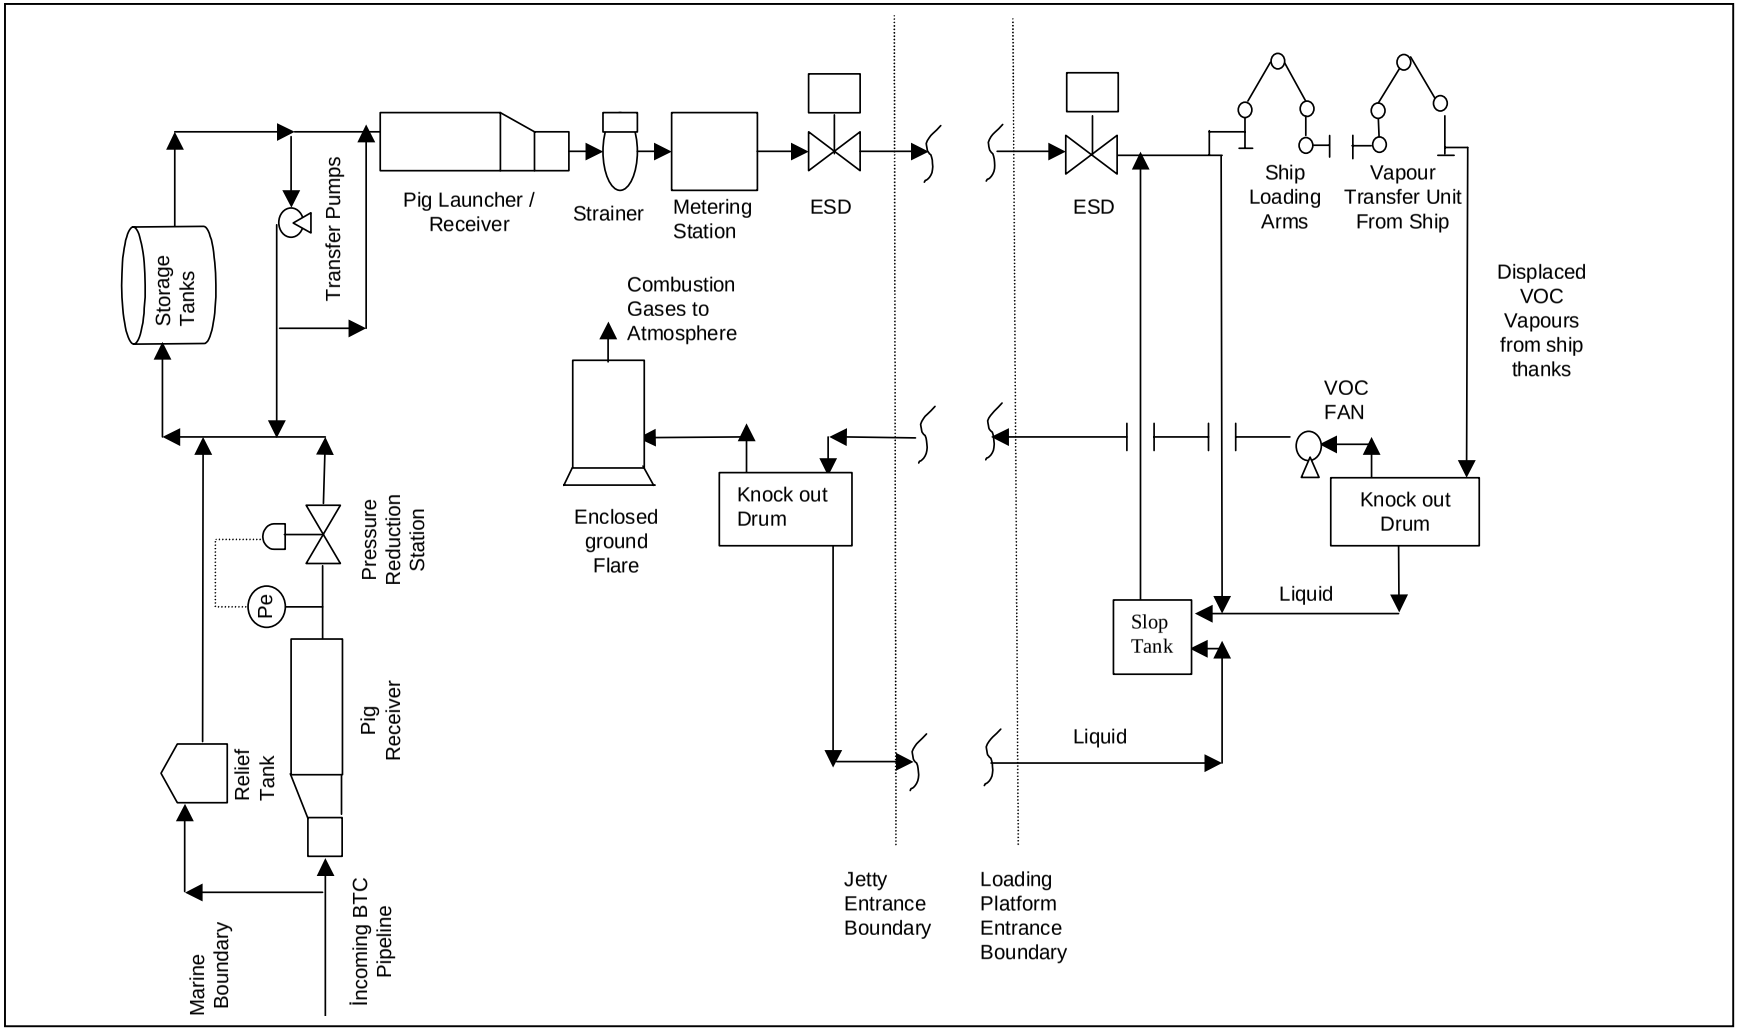

Figure 9.4 Schematic for BTC Marine Terminal

9.4.2 Receiving facilities

The Receiving Facilities serve as the interface between the continuous operation of the BTC Pipeline and the intermittent operation of the crude oil export shipping operations.

The incoming 34 inch (850mm) nominal diameter BTC Pipeline will enter the BTC Marine Terminal boundary from the north, close to the location of the proposed Tank Farm. The total area occupied by the Pipeline Receiving Facilities and Tank Farm is approximately 65ha.

The Receiving Facilities will regulate the pressure of the incoming crude oil stream such that the oil can be stored in tanks at atmospheric pressure. The Receiving Facilities will comprise the following components:

- Pig Receiving Unit;
- Surge Relief System;
- Terminal Pressure Reduction Station;
- Wax Handling System.

9.4.2.1 Pig receiver unit

Since the receiving facilities constitute the end of the BTC Pipeline, the Pig Receiver will receive pigs that have been launched down the final stretch of the pipeline from Pressure Reduction Station IPT1 (see Section 4).

The Pig Receiver will be designed to receive pigs of various types (see Box 4.1, in Section 4). Calliper and displacement pigs will be run down the Pipeline during start-up of the pipeline. Since the ACG crude is a waxy crude, frequent runs (possibly once or twice per week) with scraper pigs are foreseen. The pig receiver unit will therefore be fitted with an appropriate wax removal system. At certain time intervals (approximately once every 5-10 years) intelligent pig runs will be performed for assessing the integrity of the BTC Pipeline (see Section 4).

9.4.2.2 Surge pressure relief system

To safeguard the integrity of the final stretch of the BTC Pipeline (from Pressure Reduction Station IPT1) and the downstream BTC Marine Terminal facilities, the Terminal will be fitted with surge pressure relief valves, which will release any excessive pressure caused by transient flow conditions in the pipeline upstream of the Terminal. The Terminal will also be equipped with a surge Relief Tank, which has the capacity to hold the maximum quantity of oil that may be released during any foreseeable transient situation (such as failure of the pressure reduction system at IPT1 or unscheduled valve closures). Once normal operations are resumed, the contents of the Relief Tank will be pumped to the Terminal Storage Tanks for onward transfer to the export jetty. The Relief Tank will be of the cylindrical, vertical type according to API Standard 650. It will have a fixed conical roof design but will be fitted with an internal floating roof to minimise fugitive emissions of hydrocarbon vapours. Its dimensions will be 33m in diameter and 16m high, with a net working volume of 11,100 m^3. The relief tank will be bunded to accommodate 110 % of the net tank volume. It will occupy an area of approximately 0.60 ha.

9.4.2.3 Terminal pressure reduction station

The BTC Marine Terminal operates at relatively low pressure (the Storage Tanks operate at atmospheric pressure). The incoming BTC Pipeline on the other hand operates at significantly higher pressure reflecting the hydraulic head associated with a 120km final stretch of pipeline dropping in elevation from 1,350m to 120m above sea level. The Terminal Pressure Reduction Station serves as the interface between these two systems. It comprises a battery of pressure control valves that control the downstream pressure by regulating the flow of oil in the incoming BTC Pipeline.

From the Pressure Reduction Station the oil is routed to the storage facilities (see Section 9.4.3).

9.4.2.4 Wax handling system

ACG crude, which is anticipated to be a major constituent of the material transferred through the pipeline, has a wax appearance temperature of 37.7ºC. Since the temperature of the material in the pipeline will be below this temperature for much of its length, it is anticipated that waxes entrained in the crude oil will solidify and form lumps within the fluid. Also some of the wax may solidify on the internal walls of the pipe, thereby effectively reducing its diameter. For this reason, regular scraping will be required in order to control wax build-up in the pipeline. As set out in Section 9.4.2.1 above, a Pig Receiver will be incorporated into the design of the Terminal Receiving Facilities to catch pigs that are launched down the final stretch of the Pipeline. The wax handling facilities will deal with the wax gathered from the Pig Receiver.

A number of wax handling schemes have been evaluated. The currently favoured scheme involves re-injecting the wax into the main crude oil stream for onward transfer to the Storage Facilities before the scraper is removed from the scraper trap. The relatively small quantities of oily water effluent that will arise will be treated in the on-site oily water effluent treatment plant to the Project effluent discharge standards, which encompass World Bank standards and Turkish regulations (see Appendix D).

When the pig trap is opened, some residual wax will remain. The volume of this residual wax could be as much as 0.1 to 0.2 m^3 per each pig receiving operation. The pig and the residual wax from the trap will be dumped into a cleaning pit located immediately below the pig trap opening and will be pre-cleaned with diesel, which will dissolve any wax that adheres to the pig as well as the residual wax from the pig trap.

The dissolved wax/diesel mixture will be drained entirely to the Slop Oil Handling System (see Section 9.4.12) for re-injection back into the pipeline. There will be no residual discharges from this operation.

The final cleaning of the pig will be undertaken in the same cleaning pit, using a steam cleaner. Oily wastewater arising from this final cleaning operation will be routed to the oily water separation unit for treatment (by closing the valve to the slop oil handling system and opening the valve to the oily water treatment system).

9.4.3 Tank farm

The tank farm will be located approximately 127 to 135m above sea level to allow for natural gravity feed to the jetty and for loading. The land take for the tank farm will be approximately 65 ha**.**

The tank farm will comprise seven 150,800m³ capacity, floating roof storage tanks. Nominal dimensions of each tank will be 100m in diameter and 19.2m in height. The tanks have been designed to accommodate sloshing.

The footprint for each storage tank will be approximately 0.78 ha. The bunded areas for the storage tanks will be designed to accommodate 110% of the net tank volume and will be approximately 4ha in area. A suitable liner (potentially a bentonite mix) will cover the base of the whole tank farm to prevent any leakages through to the soil below. The liner material below the tanks will be designed in accordance with current practices for retaining fluids used in the EU landfill/hazardous waste industry. The permeability and thus integrity of the liner will be reported on and proof tested during construction, to ensure that it meets the specified requirements.

The base of each tank will be lined with 5cm sand and asphalt, which will be underlain with 10cm bitumen and gravel. A perforated steel pipe will pass beneath this layer within a layer of gravel and sand. Any leakages will be collected by the pipe and detected at the outlet. Beneath the pipeline the bentonite seal will serve to prevent leakages entering the soil. The sides of the tank bunds will be lined with sand asphalt, which is more stable in the hot weather conditions that prevail at the terminal site than most of the available alternatives.

The tanks will be constructed in accordance with American Petroleum Institute (API) 650. Each tank will be provided with six side entry mixers to prevent excessive wax formation of the crude oil within the tank.

Fixed foam rim seal fire fighting and external tank shell cooling systems will be provided in accordance with National Fire Protection Association (NFPA) codes (see Section 9.4.11).

Pipe headers and valve manifolds will be provided for loading and unloading individual tanks, as well as for transferring product between tanks. Two Transfer Pumps will be used to transfer product between the seven storage tanks and as boosters for when the transfer lines are being pigged.

Minimum safety distances between and around tanks will be in accordance with NPFA and Turkish Standards (1).

9.4.4 Transfer pipelines

9.4.4.1 Transfer lines

Twin 42 inch (1,050mm) nominal diameter loading lines, approximately 2.4km in length, will transfer product from the tank farm to the Jetty by gravity feed. Each transfer line (also referred to as loading line) will have provision for a pig launcher and pig receiver to allow bi-directional pigging of the lines. The two loading lines will be buried, and follow the route shown on Figure 9.5.

(1) The 'Charter on the Measures to be taken at the Works and Businesses which Utilise Flammable, Explosive, Hazardous and Detrimental Materials' issued by the Ministry of Labour and Social Security.

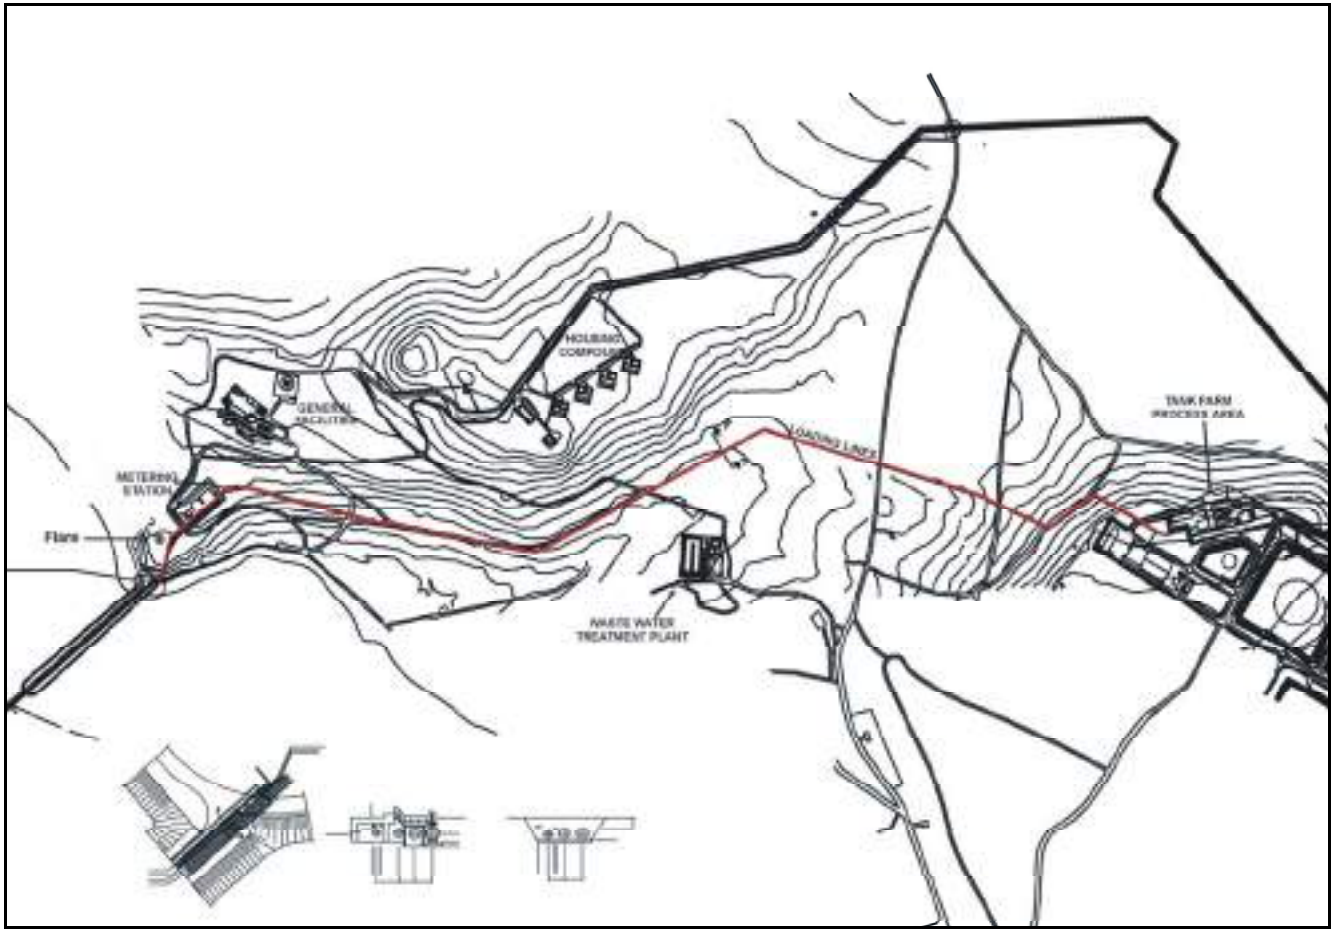

Figure 9.5 Transfer Pipeline Route and Cross-Sections

The loading lines will be laid on a sand bed in a trench that is approximately 2.3m deep, 5m in width at the bottom and 7.5m wide at the surface, see inset to Figure 9.5. Cathodic protection systems and a leak detection systems similar to that for the BTC Pipeline will be provided for the loading lines. Surge calculations have confirmed that no overpressure protection system is required for the loading lines onshore.

In the construction and operational phases of the project, the terms stated in the 'Regulation on Production, Packing and Sales of Natural, Mineral and Potable Water and Medical Water' issued in the Official Gazette dated October 18,1997 and numbered 23144 while using potable and utilisation water, and the terms stated in the circular dated April 29,1999 and numbered 5122 while supplying water by means of tankers, will be complied.

9.4.4.2 Inlet strainers

Three strainers, arranged in parallel configuration (one unit as stand-by), will be installed to protect the downstream process installations from being damaged by large solid particles entrained with the product stream. They will be tolerant to the wax content of the crude oil stream.

Maintenance and cleaning operations will be able to take place without interrupting the transfer of oil to the jetty. The sieve of the strainers will be removable to facilitate periodic cleaning.

9.4.5 Fiscal metering system

The fiscal metering system will measure sales quantities of crude oil and will be installed on the loading lines prior to the Jetty approach. The footprint of the metering system will be approximately 0.7 ha. The metering system will be of either the turbine or ultrasonic type or positive displacement (PD) type.

There will be two independent metering stations (one for each loading line). Each metering station will be equipped with seven identical meter runs, including one spare. A common shared meter prover will prove any one meter run at any time via the SCADA system. An inline analyser equipment will provide a record of quality of product being transported.

9.4.6 The Export Jetty

9.4.6.1 Introduction

Oil will be exported from the BTC Marine Terminal via tankers. A minimum water depth of 28m is required to allow safe tanker berthing and loading operations. The gently sloping seabed therefore requires a long jetty. The predominant wave direction in the bay is to the north and, to reduce the berthed vessels' exposure to these waves, the jetty will be orientated to the south.

From the shoreline, the twin 42 inch diameter loading lines will continue approximately 2,450m along the export jetty to the tanker loading berths located at the southeast end of the jetty. Two loading berths will accommodate vessels of between 80,000 DWT to 300,000 DWT.

A rock core approach causeway will extend approximately 365m from the shore in a south easterly direction, in order to gain a good depth of water. An approach trestle with pile foundations will then extend from this causeway, continuing to the southeast for approximately 1,610m. The approach trestle will then turn to face the south and continue for a further 390m to

the loading platform. An access walkway approximately 220m in length, orientated to the south, will then connect the last of the marine structures.

As stated above, the entire jetty will be approximately 2.45km in length from the shore to the loading platform. The two loading lines will run along the jetty, supported on trestles, to the loading area, transferring the crude oil for loading under gravity.

Tanker traffic will range between approximately 350 and 400 tanker movements per annum (1). The export jetty is shown on Figure 9.6.

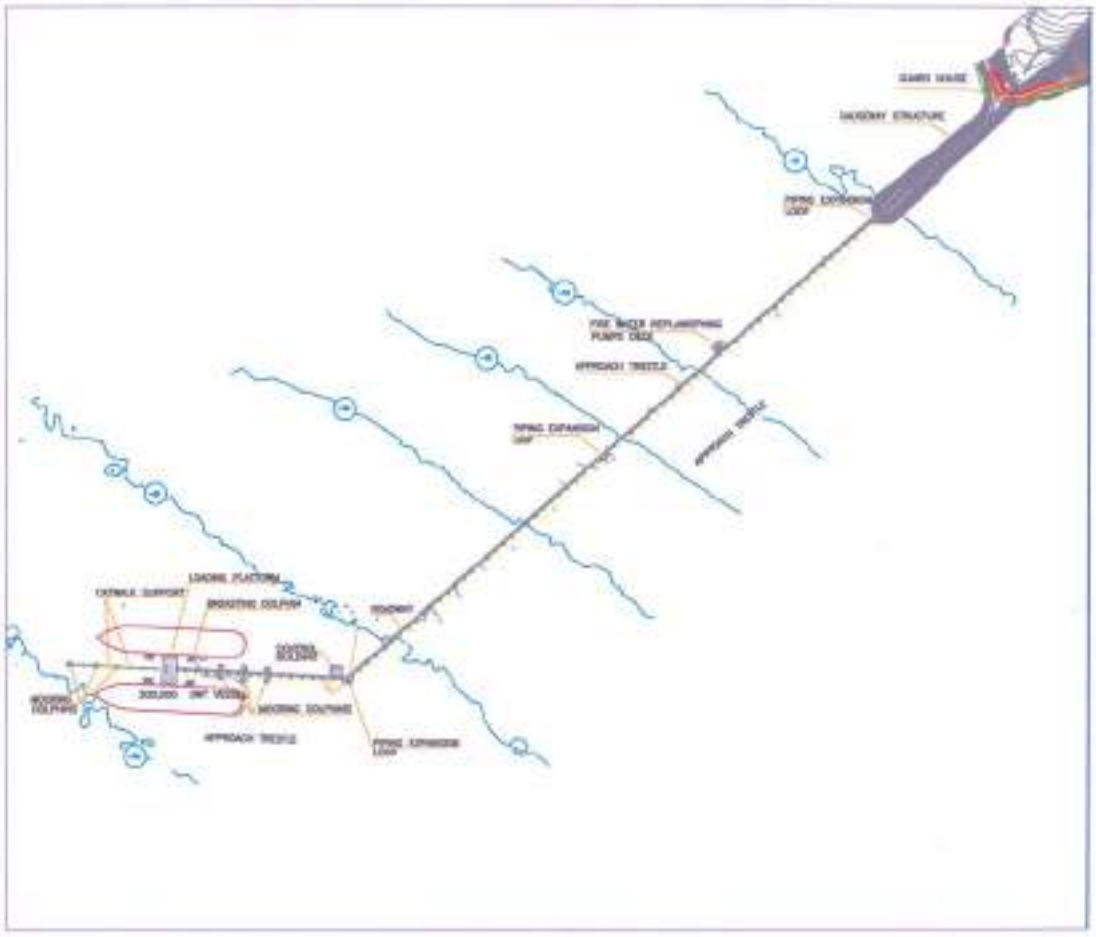

Figure 9.6 The Export Jetty Overview

9.4.6.2 Approach causeway

The approach causeway will essentially comprise a rock filled construction, with a coarsestone layer and rock armour protection (see Figure 9.7). A geotextile filter membrane laid on a stone cushion layer will separate the fill construction from the seabed to prevent settlement and the movement of material. A concrete roadway will be constructed on the causeway.

(1) Calculated in document ERM-REP-SEC-TRG-001 and advised by BOTAŞ.

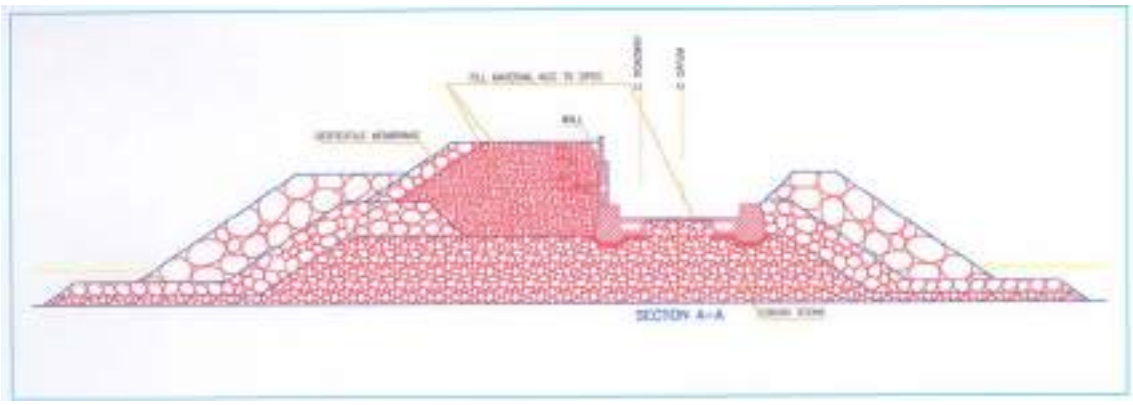

Figure 9.7 Cross section of the approach causeway

9.4.6.3 Approach trestle

The approach trestle, for access to and from the loading platforms, will be supported on steel piles and will extend from the seaward end of the approach causeway. The overall width of this structure will be 9m, 4.6m for the pipe systems and 4.4m for the roadway and pedestrian walkway.

A firewater replenishing pumps platform will be located approximately 870m from the shoreline. This will be a covered platform housing the water pumps and associated equipment. The platform will be supported on steel piles.

9.4.6.4 Jetty control building deck

The jetty control building deck will be located after the bend in the approach trestle. This will be an independently reinforced concrete platform supported on steel piles. Wastewater from the jetty control building will be collected in a $12m^3$ tank, and transported via pipeline to the new central treatment facility to be constructed within the Terminal complex (see Section 9.4.13.3).

9.4.6.5 Loading platform

The loading platform will be approximately 60m by 30m. The distance between the loading platform and moored vessels will be 5m (see Section 9.4.6.6 below). As with the approach trestle and control building deck, the loading platform will be supported by steel piles. The overlying concrete structure will be on two levels. The lower level will support the pipework and associated units and will be set at 4.55m above sea level. The upper level will be set at 7.3m above sea level and will support the surface deck structures.

9.4.6.6 Breasting dolphins

Breasting dolphins together with a rubber fender system will take the impact of the vessel when it berths and will hold the vessel against the berth on the ‘berthing line’. The ‘berthing line’ will be a set distance of 5m from the loading platforms, firstly to ensure that no contact between the tanker and the platform takes place, and secondly to provide a suitable distance for the effective operation of the loading arms.

Four breasting dolphins in total (two per berth) will be set at a level of 4.0m above sea level. They will typically be mass concrete structures with steel piles driven into the seabed. A rubber fender system will be mounted on the vessel side of each structure to take the impact of the vessel.

9.4.6.7 Mooring dolphins

These structures, designed to hold the tankers on the berthing line via mooring lines, will be essentially similar in design to the breasting dolphins described above (ie mass concrete structures supported on steel raking piles driven into the ground). The mooring dolphin sizes will vary in size from 6m x 6m to 9m x 9m and will be set at 7m above sea level and are 4m deep. They will be designed to resist the varying degrees of mooring line intensity from the berthed vessels.

9.4.6.8 Walkway

The walkway will connect the southernmost loading platform and the three remaining mooring dolphins. The catwalk will comprise a steel access walkway with an open floor grating deck, 1m wide with handrails on both sides.

9.4.7 General facilities

9.4.7.1 Administrative and operational support facilities

The administration facilities will occupy approximately 2ha in total and are listed in Table 9.1 below.

Table 9.1 Description of administration facilities at the marine terminal

FACILITY	DESCRIPTION	AREA COVERED
Central Control Building	A four-storey building located within the Administration area, will be the base for monitoring and managing the entire pipeline.	15m x 12m
Administration building	Includes a restaurant and kitchen.	30m x 12m, 30m x 12m and 48m x 7m
Warehouse	Will be used to store mechanical materials, electric materials, electronic materials, paint and office stationery.	50m x 10m
Workshop and vehicle maintenance building	Will be used to repair trucks, electronic and mechanical components	40m x 12m,
Flammable storage	For the open storage of flammable materials – the building will be a solid structure on three sides. The floor will be reinforced concrete and the building will have an arched roof	15m x 12m
Transformer and heating station	This will house the heating unit for adjacent buildings, the high and low voltage units for the entire general facility and its jetty and the emergency power unit.	25m x 13m
Guardhouse	Located at the start of the jetty	
Helipad	Located adjacent to the administration buildings	50m x 50m

9.4.7.2 Housing compound

Accommodation will be provided for BTC Marine Terminal staff in the on-site housing compound, which will occupy approximately 5.5ha. There will be four accommodation blocks and each block will be six storeys high. Each block will contain approximately 12 apartments. The apartments will house an average of four people each and the housing compound will therefore provide accommodation for 192 people. A villa will be provided for the Terminal manager and a guesthouse providing accommodation for 10 visitors is planned.

9.4.8 Power supply and electrical facilities

Power supply will be provided from the grid via a 900m distant connection. The receiving substation will be located in the tank farm area.

Emergency diesel generators will be located at the General Facilities area and the Tank Farm area. These will be of sufficient capacity to keep the Terminal operational in the event of failure of supply from the grid, thereby contributing towards reliable and smooth operations at the Terminal. The generators will be tested once per month (for approximately 30 minutes) for automatic starting during power supply outages.

9.4.9 Diesel fuel supply

Diesel fuel will be supplied via road tanker for the emergency generators. The diesel system will comprise a holding tank and diesel distribution pump. As described in Section 9.4.2.4, small quantities of diesel will also be used to clean the pig receiver assemblies following pig retrieval.

9.4.10 Water supply

The BTC Marine Terminal will have an anticipated water demand of 220m^3/day to supply the following requirements:

- potable drinking water;
- service water;
- fire-fighting water.

Table 9.2 presents the anticipated volumes of water required for operation of the BTC Marine Terminal.

A water supply, treatment and distribution system comprising the following components will be provided:

- two fire water holding tanks and one or more potable water tanks (see Section 9.4.11);
- separate modular water treatment packages for service water and potable water respectively.

The fire water holding tanks or reservoirs will be continuously kept full (on level control) to ensure continuous supply for the treatment facilities.

Service water will be distributed for irrigation and cleaning.

Potable water will be treated to comply with the World Health Organisation (WHO) Guidelines for Drinking Water Quality and Turkish Standard TS266 Water Intended for Human Consumption (see Annex D). It will then be distributed for drinking and cooking, sanitary and washing and for equipment and material cleaning.

Table 9.2 Anticipated Water Requirements for the Marine Terminal

USE	VOLUME [m^3/day]
Potable Water	
• General Facilities	24
• Housing compound	37
• Jetty	2
• Tank farm/fire fighting building	2
• Laboratory	-
• Shore facilities	-
• Guard House jetty	-
Sub-total Potable water	*65*
Service water	
• General facilities	18
• Housing compounds	43
• Tank farm	7
• Utility washing	7
• Tank washing	80
Sub-total Service water	*155*
Fire water	
Volume of water in fire water tank	2 x 3400m^3 reservoirs
TOTAL	**220m^3/day + Fire water**

Source: [Ref 1]

Hydrogeological investigations are ongoing [Ref 2] to confirm the most suitable source of water supply for the BTC Marine Terminal. Based on the findings so far, water will most likely be supplied to the Terminal via pipeline from new wells which will be located within the Burnaz Springs area to the south of Turunchi village, approximately 15km east of the existing BOTAŞ Marine Terminal. This potential source is currently used by the existing BOTAŞ Marine Terminal and several other industrial users in the area. It is considered to be a sustainable source of supply for the additional BTC Marine Terminal demand, but this is being confirmed via ongoing investigations and consultations. A water supply line, which will run parallel to the water supply line serving the existing BOTAŞ Marine Terminal, will need to be provided.

The water will be treated at the BTC Marine Terminal[1]. Once finalised, the selected water supply option will be subjected to Environmental Appraisal.

1 Water supply will be in accordance with the provisions of the Regulation on Production, Packing and Sales of Natural, Mineral and Potable Water and Medical Water, Official Gazette Pronouncement No 23144 of 18 October 1997 and the terms stated in Circular No 5122 dated 29 April 1999.

9.4.11 Fire fighting system

A fire fighting system will be provided for the BTC Marine Terminal in accordance with ASME B31.8. A fire ring main will be installed and hydrants will be connected to the main line along its length. At the tank bund area fixed foam/water monitors will be installed. A fixed foam system will be fitted for the storage tanks. Fire protection measures will be in accordance with NFPA, ASME and Turkish codes (see Section 9.4.3).

The fire fighting system will comprise the following main components:

- two fire water reservoirs (3,400 m^3 nominal capacity each, sized for two hours combined storage capacity);
- static pressure tank (50m^3);
- three fire water pumps;
- foam storage and dosing unit;
- ring main, hydrants, monitors and connecting lines;
- two fire water trucks with foam concentrate storage and monitors;
- hand held fire fighting extinguishers, hose reels etc.

In the event of a fire, any oil-contaminated firewater will be drained via the primary withholding pond upstream of the stormwater pond (rather than directly to site effluent discharge). This will enable the plant to retain any oil-contaminated firewater for subsequent treatment in the site effluent treatment plant before discharging from the site.

9.4.12 Slop oil handling systems

Any oil that arises as a result of equipment maintenance or plant malfunction is termed ‘slop oil’. This oil is collected in a closed slop oil handling system, comprising a collection tank, recycle pump and dedicated piping to enable all slop oil to be recycled back to the process.

Given the dispersed distribution of the various terminal facilities across the Ceyhan site, it is not feasible to have a single slop oil handling system. There is therefore a discrete slop system serving the onshore facilities and another serving the jetty. Both systems are functionally similar; oil arisings from batch operations or maintenance are routed to a dedicated slop tank and the contents are then pumped back into the system. There are therefore no oily waste arisings from batch oil loading operations, routine change-out of strainers, change out of pig traps or draining of process equipment or metering station facilities.

9.4.13 Drainage and effluent treatment and control

9.4.13.1 Effluents requiring treatment

Aqueous discharges arising from the operation of the BTC Marine Terminal are summarised in Table 9.3. These apply to normal operations, ie they do not include storm events when run-off volume flows will clearly increase and be highly variable.

Table 9.3 Approximate Operational discharges from the BTC Marine Terminal.

Discharges	primary holding pond	treated wastewater	Irrigation and/or soakaway	24 m^3 per day
	general facilities	treated wastewater	Irrigation and/or soakaway	24 m^3 per day
	housing compound	treated wastewater	Irrigation and/or soakaway	38 m^3 per day
	Jetty	treated wastewater	Irrigation and/or soakaway	1.5 m^3 per day
	guardhouse	treated wastewater	Irrigation and/or soakaway	1.5 m^3 per day
	Tankfarm	treated wastewater	Irrigation and/or soakaway	2 m^3 per day

A central wastewater treatment plant will process the wastewater from the terminal facilities. The wastewater treatment plant will comprise a primary holding pond, biological wastewater treatment plant and storm water pond. The collection of stormwater and sewage for Terminal onshore facilities is illustrated in Figure 9.8.

9.4.13.2 Oily water treatment

Drainage from contaminated or potentially contaminated areas (vehicle washing, machinery etc) will be treated in an oily water system. Oily water sources at the marine terminal will include the following:

- storage tank bunds (tank roof runoff, tank drain, storm water in the bund area etc);
- process area bunds at the receiving station and the relief tank bund;
- fiscal metering station bund;
- car park area.

The oily water treatment will comprise three stages of treatment in series:

- a grit chamber for solids removal by gravity separation;
- a gravity oil separator whereby surface oil separates out from the denser aqueous phase;
- a coalescer for accumulating dispersed oil droplets from the residual aqueous phase.

The treated aqueous phase will then be routed to the stormwater pond of the wastewater treatment plant (see Section 9.4.13.4). The oil phase streams from the separator and coalescer stages will be routed to the slop oil handling system (see Section 9.4.12). Solids collected in the grit chamber will periodically be collected, washed and spread onsite.

9.4.13.3 Sewage treatment plant

The sewage treatment plant will treat all black water and grey water arisings at the Terminal. The plant will be a self-contained activated sludge package unit and will discharge via the stormwater pond. Sewage collected at the Jetty will be tankered to the central sewage treatment plant.

9.4.13.4 Discharge of treated effluent

All liquid effluent leaving the onshore facilities will be discharged via the stormwater pond and then through a single discharge location. All effluents will meet the requirements of World Bank guidelines and Turkish Regulations (see Appendix D).

The stormwater pond will be designed to hold approximately 30 days effluent and surface drainage at normal flow rates. The philosophy will be to maximise ullage within the withholding pond and stormwater pond such that the plant operator will be able to discharge effluent from the site under (semi-batchwise) controlled conditions according to the quality of treated effluent within the stormwater pond.

Both the contents of the stormwater pond and the site effluent outfall will be fitted with spot sampling facilities. The activated sludge treatment and oily water separator outlets will also be amenable to sampling. A sampling regime will be established for routine on-site determination of oil-in-water and coliforms. The operator will therefore have the facility to control release of treated effluent from the site according to effluent quality.

Irrigation is the preferred option for treated effluent. The feasibility of this is subject to ongoing evaluation. In any event, the discharge will have the facility to be routed to a tilebed seepage shaft unit. The location of this shaft will be 1.5km distance from the unconfined aquifer so as to minimise the likelihood of contamination of groundwater. This is subject to further investigations and is described fully in Section 12 of this report.

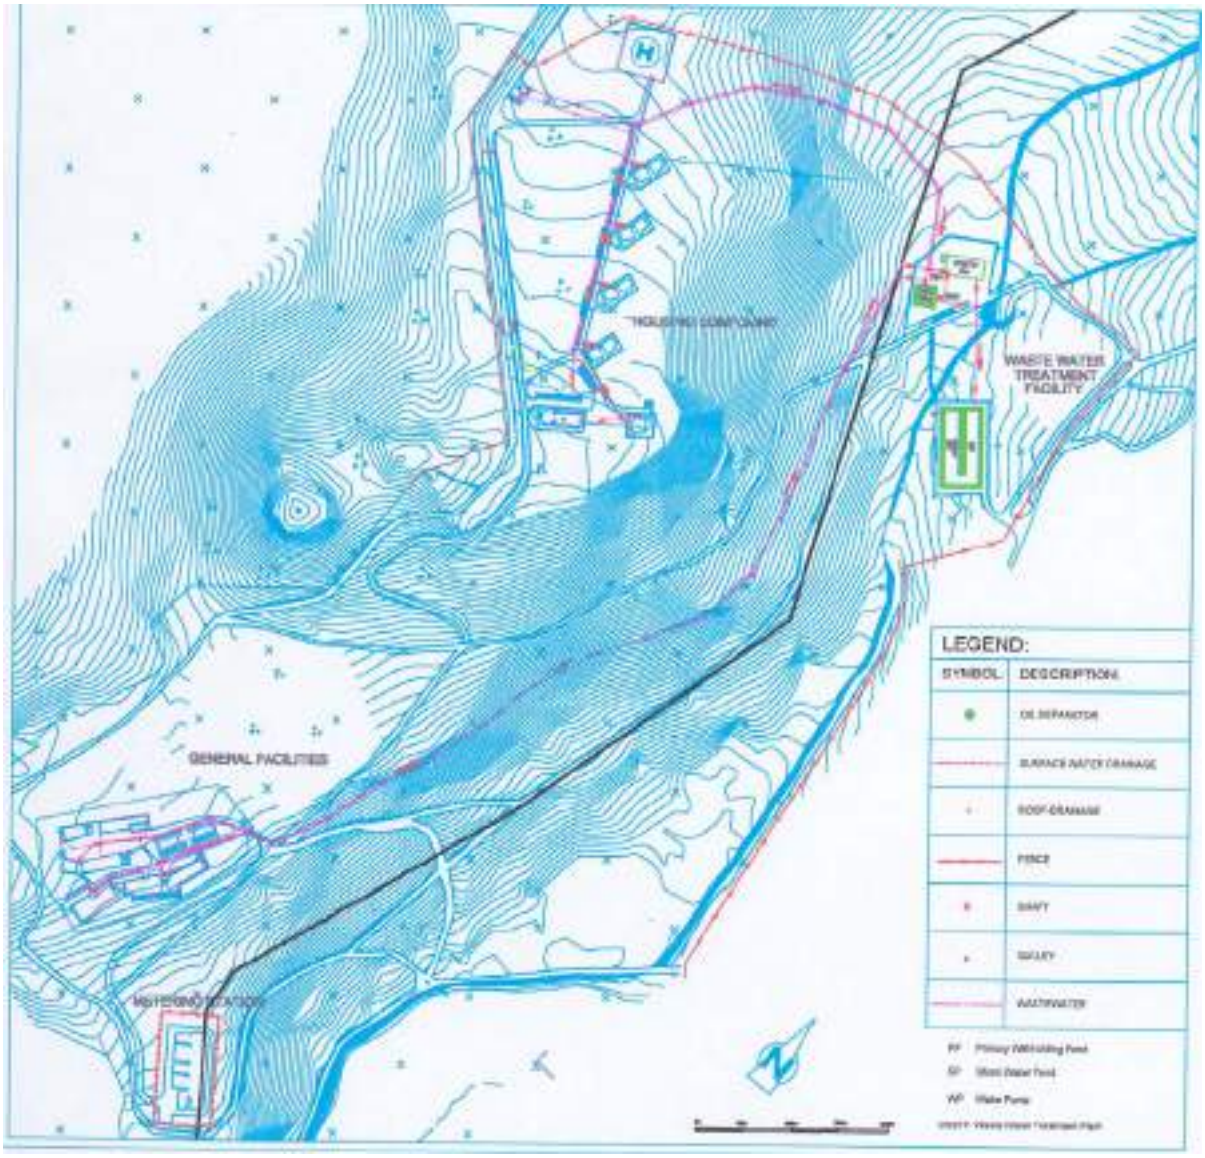

Figure 9.8 Collection of Oily water and sewage from onshore facilities

9.4.13.5 Effluent treatment of the marine facilities

There is no requirement for the treatment of ballast water, as only vessels with segregated ballast will be loaded at the jetty. Ballast water, therefore, will not be contaminated with oil and can be discharged directly to sea without treatment.

Surface drainage at the loading deck of the jetty will be routed to a dedicated oily water separator, which will treat the aqueous effluent to 5ppm residual hydrocarbons, within Turkish Regulations and World Bank guidelines. The treated effluent will be discharged to sea from the end of the jetty.

The oil phase will be routed to a slop tank, which will also collect any oil spillages in the vicinity of the loading arms. This tank will be periodically emptied by vacuum truck and the oil transferred to the slop oil handling system onshore. (See Section 9.4.12)

9.4.14 Enclosed Ground Flare (EGF)

During tanker loading the air space in the tanker's compartments will be displaced; this displaced gas will contain volatile organic compounds (VOCs). Consistent with international best practice, this displacement gas will not be discharged directly to atmosphere; rather, it will be routed to an enclosed ground flare (EGF) for combustion of VOCs prior to emission to atmosphere. The selection of EGF as the preferred method of VOC statement follows a detailed study (see Section 2.4.2.3).

The EGF will be located adjacent to the jetty entrance. A 24 inch (600mm) nominal diameter waste gas line, approximately 2,800m long, will be installed to convey up to 20,000 Nm^3h^{-1} of waste gas from the tanker loading area to the EGF.

The flare stack will measure 25m above ground level with a diameter of 10m and the system will have a landtake of approximately 0.16ha. Figure 9.9 shows a schematic diagram of a typical EGF and Figure 9.10 shows an example of an EGF once installed.

An airblower will enable the facility to achieve smokeless flaring and a pilot and purge gas system will be provided to assure safe flare operation.

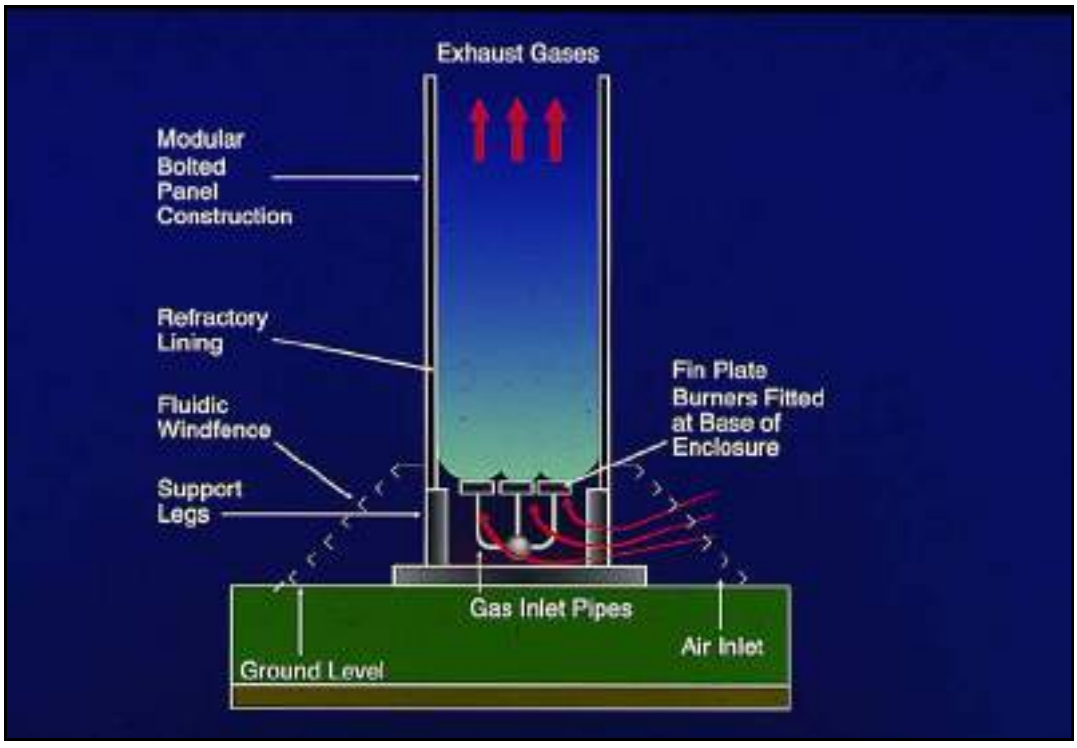

Figure 9.9 Schematic Diagram of a Typical EGF

Figure 9.10 Example of a Typical EGF

9.4.15 Lighting provisions

Outdoor lighting will be supplied from distribution boards that are located in the low voltage switchgear rooms in the Ceyhan Terminal area and at the Jetty.

Along the Jetty there will be street lighting fixtures, which are equipped with either high pressure mercury vapour lamps up to 150 W or fluorescent lamps up to 2 x 58 W. To minimise the voltage drop on the street lighting circuits of the Jetty distribution boards suitable for outdoor installation will be used. These boards will be equipped with two feeders for the lighting circuits and two additional socket outlets (400 V, three-phase, 32 A and 230 V, single-phase, 16 A) for general purposes.

The watch towers will be equipped with two swivel-mounted flood light fixtures, which will be equipped with high pressure mercury vapour lamps up to 400 W, mounted on a suitable location such as the balustrade.

The main supply for circuits for street lighting, flood lights and (if required) also for the circuits of shelter lighting and selected area lighting will be 400 V AC. To arrive at the lighting supply voltage of 230 V AC, each lighting pole will be equipped with an inside located fuse box; for shelters the lighting will be divided into three circuits.

All circuits with twilight switches will be provided with a manual override so that operation from the respective panel will be possible. Floodlights on the Jetty will also be operable from the central control system. Each floodlight circuit will be equipped with an additional switch,

integrated in the front door of the respective distribution board. The street lighting fixtures will be installed on poles with a height of 10m. The poles and all other steel construction elements provided for outdoor lighting will be hot dip galvanised. Lighting fixtures, equipped with fluorescent lamps up to 2 x 58W, for the illumination of selected areas will be installed on poles.

All lighting and socket outlet circuits will be equipped with moulded-case circuit breakers for switching operations and fault clearance instead of fuses. For circuits with a rated current up to 63 A, the use of miniature circuit breakers will be acceptable.

9.5 DESIGN CONSIDERATIONS

9.5.1 Designing for geohazards

The geohazards baseline for the site of the proposed BTC Marine Terminal is described in detail in Section 10.

An extensive geohazards study has been undertaken with the collaboration of a group of world class experts to characterise the seismic faults in the vicinity of the BTC Marine Terminal site for detailed design purposes [Ref 3]. This has enabled the Project to take full account of geohazards in the design of the storage tanks, the relief tank, the jetty and all the other facilities proposed for the Terminal site.

The study has provided the following:

- confirmation that the proposed site is acceptable for locating the Terminal and all associated facilities;
- confirmation that the Terminal facility can be economically designed and built using conventional and proven design and construction techniques;
- confirmation that the Yumurtalik fault is an active fault but that it does not pass through the proposed location of the BTC Jetty;
- the basis for establishing design parameters such as peak ground acceleration, seismic design for all major plant and equipment and design sloshing period for storage tanks.

9.6 CONSTRUCTION AND COMMISSIONING

9.6.1 Introduction

Construction of the onshore and marine facilities will be the subject of separate construction contracts. While the Construction Contractors will each be required to comply with all the requirements of this EIA Report, including the various Management Plans appended hereto, they will ultimately determine the precise approach they will follow to build and commission the plant and facilities for which they are responsible. Nevertheless, this section indicates the broad approach anticipated during construction and commissioning of the BTC Marine Terminal.

9.6.2 Construction camps and prefabrication areas

The construction camps for both Contractors (Onshore and Offshore) will be located north-west of the new tank farm area. They will be entered through a temporary gate beside the west main gate of the existing BOTAŞ Marine Terminal.

Water and power will be tapped from the supply of the pump station of the Yumurtalik - Kirrikale Pipeline and metered and will be compensated to BOTAŞ.

Disturbance to the operations of the existing BOTAŞ Terminal including transportation of construction materials through the Terminal will not be permitted, the following measures will be put in place.

- The entire area of the proposed BTC Marine Terminal will be fenced to avoid any disturbance to the operations of the existing BOTAŞ Terminal.

- The prefabrication yard for the offshore contractor will be located adjacent to the eastern main gate of the existing BOTAŞ Terminal. The size of the yard will be approximately 91,000 m^2. The yard will be fenced and have a separate entrance gate.

9.6.3 General good site management

The Construction Contractor will be required to adhere to the environmental, health and safety regulations and criteria, which are set out in the Environmental Specifications to Tenderers document, and in the relevant Management Plans produced as part of this EIA Report.

A number of pre-construction environmental surveys of the BTC Marine Terminal site and the vicinity will be undertaken in those areas where there is currently insufficient data to fully assess the significance of impacts, or where such data would enhance the ability of the Project to manage environmental issues during construction and operation of the Terminal. In a number of cases the results of these surveys could influence design options such as the location of water abstraction for example. Identified pre-construction studies to which the Project is committed are as follows:

- detailed botanical and faunal surveys will be carried out at specific locations, such as along the terrestrial route of the loading lines and the water supply line;

- due diligence soil sampling will be carried out in the vicinity of the proposed location for siting of the BTC Tank Farm;

- water supply sustainability studies (pump tests) will be carried out for potential groundwater sources for the Terminal.

9.6.4 Onshore construction programme

The construction programme will be of approximately 20 months duration, commencing in late December 2002. In this regard the Terminal's onshore facilities comprise a relatively simple set of plant and equipment. Having been the subject of in-depth field investigation and (ongoing) detailed design (with particular attention paid to designing for geohazards and mitigating

potential environmental and social impacts), construction of the onshore facilities will entail largely conventional and proven construction techniques.

Construction of the two loading lines will entail the same construction methodology and reinstatement standards as those adopted for the main BTC Pipeline, which is described in detail in Section 4.

Similarly, hydrotesting of the plant and pipelines will be undertaken to the same standards as those for the main BTC Pipeline with the anticipated added advantage of being able to use seawater as the test medium at the Terminal (see Section 9.6.6).

Reinstatement will be undertaken to the full provisions of the Reinstatement Plan.

9.6.5 Marine construction works (causeway and jetty superstructure)

It is anticipated that the marine construction works will take 20 months. The piling work is the main aspect of the jetty construction and will take approximately 13-14 months to complete. The causeway structure will be constructed first (taking three to four months) from the land. The rock core fill will be pushed from the shoreline until it is higher than the water level. Tracked machinery will then drive on the causeway and deliver the rock core fill, steadily progressing out to sea.

The material for causeway construction will be sourced from two licensed stone quarries within the District of Ceyhan. They are both located at a distance of approximately 16-20km from the BTC Marine Terminal.

As the approach causeway extends to the jetty, it is anticipated that barges will be used to lay the filter stone layer (although the actual method employed will be determined by the contractor). The armour rock layer is likely to be placed by crane, since this allows more accuracy than a barge. If barges are used, they will drop the rock from the base of the vessel. A mixture of both approaches may be adopted by finishing the armour layer by crane, as a last phase, once the majority has been placed by barge.

The suspension of fines from the core material into water will be reduced to the extent possible. The Environmental Specifications require that fines are removed and a certain grade of material is used. However, it is likely that there will be some release of suspended sediment.

The jetty will be piled by barge using a large crane (pile diameters are approximately 1.5 and 1.2m in diameter). One piling barge with two other support barges will most likely be required. The construction of the jetty will progress from the shore to sea. The piles will be driven through the sand and clay and seated onto the underlying rock base. Hence the piles will be driven until there is no more movement.

However, there is a possibility that some piles would be driven into the rock (no more than 5%). This would mean drilling into the rock and securing the piles with anchor bolts. The drilling would be through the concrete pile and the majority of the displaced sediment would be contained within the pile itself. There should be no displacement of sediment as the piles would be driven by hammering and not vibration piling.

For the superstructure and platforms both pre-cast concrete elements and *in situ* pouring are anticipated.

The control buildings will be built using conventional methods of construction.

9.6.6 Commissioning

Pre-commissioning and commissioning works for the BTC Marine Terminal will commence following the completion of mechanical works. Such activities are summarised in Box 9.1.

The pre-commissioning activity with the greatest potential for environmental impact is the hydrotesting of plant and pipelines.

The various plant and equipment comprising the BTC Marine Terminal, including the two loading lines, will require pressure testing prior to commissioning. Seawater, possibly inhibited with either corrosion inhibitor and/or oxygen scavenger chemicals, will be the primary medium used for executing the hydrotest.

The use of particular inhibitor chemicals will require the prior approval of the Project and the authorities. In any event, the concentrations of these chemicals will be very low (of the order of a few ppm).

It is expected that hydrotest water will, wherever practicable, be re-used from one pressure test to the next. Nevertheless, spent hydrotest solution will be discharged to sea at the end of the jetty. This will be done in such a way as to maximise dispersion.

9.6.7 Construction workforce

The following numbers of construction workers will be required for the construction of the BTC Marine Terminal:

Table 9.4 Estimates of Employment Opportunities during Construction

Task	Numbers of Workers	Skills Mix % (unskilled: semi-skilled and skilled)	Duration (peak employment for semi-skilled and skilled employees only)
BTC Marine Terminal – offshore			
Construction	120 workers	20:80	24 months
BTC Marine Terminal – onshore			
Construction	250 workers	40:60	30 months

9.6.8 Management during construction

Environmental issues will be managed during construction through implementation of the EMMP and support plans that are described in full in Appendix C. The requirements of these plans have been incorporated in the Invitation to Tender documents for the Construction Contractors and the successful bidder will have to adhere to them in full.

Box 9.1 Commissioning and Start-up Activities

Vessels
- dry out, if required, open vessel and install materials, if any;
- close after proper execution of closure permits.

Pumps and Drivers
- charge the lube oil, seal oil and oil cooling systems;
- operate equipment and make vibration, trip, governer and safe device checks and any operating tests and adjustments;
- obtain the assistance of a service engineer for technical advice during installation or start up, if desired;
- replace driver and equipment;
- maintain records, as required.

Tanks
- witness test and inspections as necessary (including hydrotesting);
- close after proper execution of closure permits.

Piping
- Hydrotest all piping;
- check pipehangers, supports guides and pipe specialities for hot settings and make minor adjustments, as necessary;
- install permanent filter elements, as required;
- verify that specified valve packing has been provided in valves installed;
- correct support, vibration and thermal expansion problems detected during commissioning;
- retorque all hot and cold service bolting during commissioning and start up, as required.

Electrical Power and Lighting Systems
- energize all substations after completion of all tests;
- check phase sequence, polarity and motor rotation;
- check installation of emergency power and lighting systems, including light intensity;
- provide a report for work completion.

Instrument Systems
- isolate or remove components for flushing operations and reinstall them on the completion of these operations;
- install any sealing fluids, as required;
- fully pressurize and energize the transmitting and control signal systems;
- provide a schedule of recorder charts.

Water Treatment
- make the necessary operating tests and adjustments to water treatment systems;
- obtain the services of a water consultant for operation, if required;
- purify potable water systems.

Waste Disposal
- operate all equipment and supply all chemicals and agents related to waste treatment;
- obtain the services of a waste treatment consultant for operation, if required.

Buildings
- operate heating, ventilating and air conditioning units and make all performance tests;
- obtain certificate and use, if required.

Miscellaneous Equipment
- check clearances on materials handling equipment;
- make all final adjustments during run-in and conduct any required performance tests;
- obtain a service engineer for technical assistance during installation or start up, if required;
- as required, obtain certification that all lifting and materials handling installations and other items of equipment comply with government regulations.

9.7 OPERATION AND MAINTENANCE

9.7.1 Operational philosophy

The following operational principles form the basis of the BTC Project:

- centralised remote operation and control of the entire Pipeline system, including the Pumping Stations and the Receiving Facilities of the BTC Marine Terminal (up to the Pressure Reduction Stations);
- simple operation with maximum possible support of automatic sequences;
- automatic control of unscheduled events by self-contained safety equipment;
- remote operation with LDS integrated into the SCADA System;
- the system operation shall ensure the delivery of the Design Flow Rates, with pump low flow / high flow protection and pipeline leak detection;
- slackline operation, while permissible, will be minimized to provide best conditions for leak detection; available equipment such as control valves will be operated to increase the inlet pressure in downstream stations to reduce slackline;
- controller parameters, setpoints, ramp function, software, etc will at all times be adjustable within a reasonable range in order to allow system tunings or modifications.

This operational philosophy will provide the basis for safe, reliable, steady state operations that are well within the design limits of the Pipeline system.

9.7.2 Maintenance philosophy

The basic principles of the overall maintenance philosophy for the BTC Project include the following:

- maximum use of easily maintained equipment;
- standardisation of the design of process facilities, instrumentation, procedures and documentation;
- maintenance of a spares inventory at suitable locations;
- training of personnel to effect a timely repair of failed equipment;
- use of vendor support;
- regular, preventative maintenance programs;
- written maintenance plans covering detailed maintenance procedures.

9.7.3 Marine operations

9.7.3.1 Introduction

An operational permit will be obtained from the Undersecretariat of Maritime Affairs after the general evaluation of the BTC Marine Terminal.

Operational restrictions will exist around both the existing BOTAŞ Marine Terminal and proposed BTC Marine Terminal. There is a Security Exclusion Zone around the existing jetty and there will be one placed around the proposed jetty as well which will comprise an area of 400m along either side of it (see Figure 9.11). In this Zone marine activities will be controlled and in some cases excluded (eg fishing, discharging of ballast, refuelling of vessels, waste disposal etc). There is a one nautical mile Operating Zone in the bay in which anchoring of ships, fishing and recreational activities are all prohibited. Access to the Security Exclusion and Operating Zones, and operations within them, will be controlled by the Ceyhan Harbour Authority.

9.7.3.2 Movement of tankers into the loading area

A total of around 350 additional tanker movements per year are expected once the proposed BTC Marine Terminal has become operational.

Tankers will approach the Terminal via the Gulf of Iskenderun. There are no designated shipping lanes within the Gulf [Ref 4]. Tankers servicing the BTC Terminal will then be directed to the loading jetty under the supervision of BOTAŞ tugboats and pilots (see further below).

The maximum speed at which tankers will be allowed to approach the jetty will be established and strictly enforced.

Marine traffic within the jetty area will be controlled by the Harbour Authority in accordance with the Ceyhan Harbour Operating Regulation. Ships entering the Bay of Iskenderun will be required to obtain prior permission from the Ceyhan Harbour Authority (which has a branch at the existing BOTAŞ facility).

9.7.3.3 Tanker loading

The design ship loading rate at each berth will be 9540m^3/h. Berthing, unloading and un-berthing of tankers from the loading jetty will therefore take up to 40 hours (assuming the largest design standard vessel of 300,000 DWT. The BOTAŞ pilot will remain responsible for the ship during this entire period.

One person will operate the loading arms from the stowed into the connecting position. The loading arms will be controlled by either radio or local panel control, for manoeuvring from and into stowed position, as well as for coupling procedures.

Loading arms will be fitted with range sensors to identify the position of the tanker. The sensors will generate flashing and sound alarms at pre-determined tanker locations to initiate valve closure and emergency release before the loading arm reaches its structural limit. A three stage alarm system will operate and if the tanker stops drifting before reaching the point of stage

three, no emergency release will occur. In case of an emergency release, the filled loading arm will be balanced so as to rise vertically.

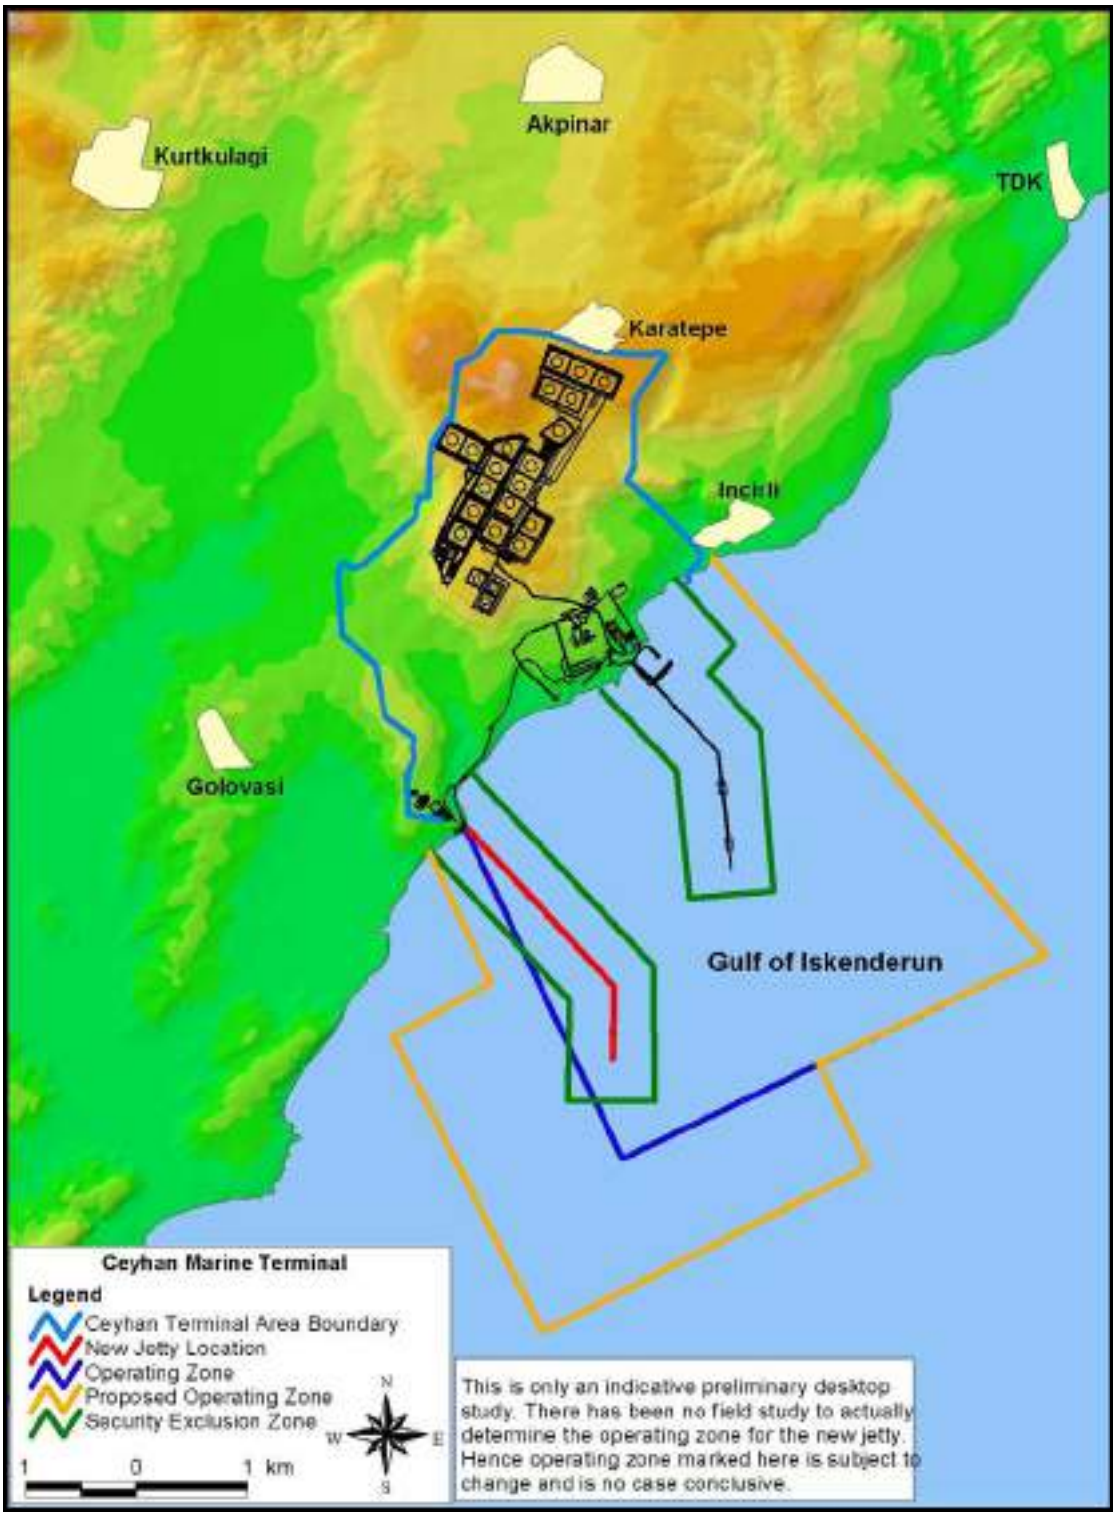

Figure 9.11 Exclusion Zone and Operating Zone

The Emergency Release System will comprise of a non-sparking emergency release coupling with a fire safe valve on each side. In addition to the electric and hydraulic safety devices, a mechanical interlock will be provided which will prevent separation before the isolation valves are closed, thereby safeguarding against unintentional release.

9.7.3.4 Tanker servicing facilities

From an anchoring zone defined in the Ceyhan Harbour Operating Regulation, ships will approach the loading jetty under the guidance of tugboats and BOTAŞ pilots. On approaching the facility, the tankers will be required to contact the BOTAŞ facility to give notice of their intent to enter the operating zone. A BOTAŞ pilot will then meet the tanker and takes responsibility for the ship during the entire berthing, unloading and unberthing process.

The following vessels will be obliged to employ a pilot:

- Turkish merchant vessels with a capacity of 1000 te GRT and more;
- foreign flag vessels with a capacity of 150 te GRT and more.

The pilots will board vessels in the southern area of the outer harbour limit and advise the master on local conditions, regulations and berthing on arrival at the harbour.

Each tanker will be accompanied by 2-4 tugboats depending on the size of vessel. Six tugs are currently in operation for the existing BOTAŞ facility, and it is anticipated that three additional tugs will be added and possibly more, to support the BTC Marine Terminal operations. Similarly, there are currently seven pilots working for the existing facility, which will increase to 12 (and possibly more) in the future. These tugboats and pilots will operate both jetties (ie the existing BOTAŞ Terminal and the BTC Marine Terminal).

9.7.3.5 Refuelling operations

Within the Security Exclusion Zone, refuelling of vessels will be prohibited.

9.7.4 Operational workforce

The BTC Marine Terminal is expected to employ 200 workers, comprising approximately 10% unskilled and 90% semi-skilled and skilled.

9.7.5 Emergency shutdown systems

There will be a dedicated, independently operating Emergency Shutdown System (ESD) for protecting the Pipeline and Terminal in the event of operating conditions deviating excessively from design conditions. The ESD will trigger the Station Control System (SCS) in order to shutdown other subordinated systems.

The ESD System will drive all safety related inhibits and interlocks. The SCS may initiate the closure of the ESD valves under certain operational situations either by automatic or manual command.

Other than the ESD there will be:

- pipeline shut down (initiated by the SCADA system);
- unit shut down (initiated by the unit control system, UCS);
- cascade shut down within the operation philosophy of the SCS.

The pipeline will be operated in accordance with the Operational Philosophy, which is summarised in Section 9.7.2 above. This will also include operational shutdown procedures (OSD), which will be initiated and executed by the SCADA System, SCS or UCS.

The objective of the ESD System will be to avoid any harm resulting from hazardous situations and reduce the consequences of an event on the pipeline or the environment.

To fulfill this requirement, the ESD System will offer more than a simple shutdown logic with a few failsafe functions. The extended functionality of the entire ESD System will incorporate the following basic functions:

- monitoring the correct function of SCADA System, UCS and SCS in conjunction with safety relevant key parameters;
- control and monitoring function for safety relevant station equipment units without integrated failsafe controllers;
- emergency shutdown function.

In order to monitor the correct operation of the SCADA System, SCS, UCS and equipment without integrated control units, the ESD System will collect safety relevant parameters independently of these systems and will initiate shutdown action in case of:

- detection of an illogical status of station equipment;
- process parameters which have reached defined limit values;
- a manual trip by push button has occurred.

To prevent serious damage to the pipeline or Terminal facilities, the ESD System will block dangerous actions and shut down station equipment or the relevant section(s) of the station safely. If the malfunction affects other local stations of the wider pipeline system, an ESD System with an overall view to the entire pipeline and the Terminal will be activated to handle this situation.

To provide this functionality, the BTC Pipeline and Marine Terminal will utilise a control logic system with a hierarchical structure of at least two levels:

- Overall ESD System;
- Terminal ESD System.

The installation of appropriate transmission facilities with redundant and independent communication lines will ensure a safe transmission of information between the individual ESD Systems at the Terminal (and Pipeline AGIs along the route) and the Overall ESD Systems at the two Control centers (ie Sangachal and Ceyhan).

9.8 DECOMMISSIONING

The project has a design life of approximately 40 years. It is currently envisaged that the various components of the Project (including the marine terminal) will be decommissioned thereafter.

9.8.1 Onshore project components

Where feasible, above-ground facilities will be left in place for further use. Where that is not appropriate, facilities will be decontaminated before abandonment in place or entirely dismantled and removed. Wherever possible, equipment and materials will be collected for reuse. A land contamination survey will be undertaken and site remediation will be undertaken if necessary.

It is likely that most or all of the equipment dismantling will take place within the confines of the Terminal. Largely, this means that any spillages resulting from the dismantling process will be contained within the site drains.

Pending governmental approval, buildings will be provided to local organisations for reuse. Otherwise, they will be demolished and properly disposed of according to the BTC Project's Waste Management Plan.

9.8.2 Onsite pipelines

The two loading lines will be cleaned, filled with inert gas, air or water and capped. They will be abandoned in the ground in a condition that is acceptable to the responsible authorities. This is seen to be the preferable option in environmental terms for the pipelines – the alternative, namely removing the pipes would involve excavation and disturbance to the environment. A more detailed account is presented in Section 4 dealing with decommissioning of the main BTC Pipeline.

9.8.2.1 Jetty

The jetty will be dismantled from the seaward end by crane barge. The rock and steel structures will be removed from the site by barge and taken to a quayside.

The modules and structural sections will then be placed on a lay-down area that allows access by workers during the deconstruction process. The objective of this process will be to prepare the various constituent parts of the structure to a condition whereby they can be reused, recycled or disposed of as waste. Some components may be re-usable and potentially be salvaged for resale. However, the potential for this is considered to be small because the components may be outdated, worn or the specification may make them unsuitable for re-use. The principle value of the components is anticipated to be in recycling. Material such as steel may be recycled through a steel foundry, thereby providing an overall resource saving through negating the need for refining the corresponding quantity ore.

The dismantling of the actual structures will be performed by teams using gas axes, electrical saws or mechanical shears. Structural steel will be reduced in size to pieces approximately $1m^2$ which can be fed into a furnace.

Where reuse is possible, the materials will be cleaned using high pressure water/solid CO_2. If reuse is not desirable, the steel and rock materials will be disposed of by a licensed waste contractor in accordance with the Waste Management Plan (Appendix C3).

9.8.3 Inventory of emissions and discharges

9.8.3.1 Emissions, discharges and wastes during construction

Emissions to air

There will be several key emission sources associated with the construction of the marine terminal, namely:

- intermittent, fugitive emissions of dust during the construction period;
- emissions from the exhausts of vehicles used for the transport of the workers, the transport of construction materials and of basic equipment;
- vessel engine exhausts;
- diesel fired power units and generators.

In addition, a number of wastes generated during construction (eg excess bitumen, oil wastes, paint sludge, polystyrene etc) will be incinerated in a mobile incineration system and this process will be monitored (ie measurement of ambient air quality and stack emissions).

The construction fleet will number approximately six vessels. There will be a significant amount of activity from construction and support vessels during the installation and commissioning stage. It is anticipated that the following vessels will be deployed:

- crane barge;
- barge with piling equipment;
- two support barges;
- two tug boats.

Vessels will generate atmospheric emissions during the installation and commissioning phases as a result of the combustion of marine diesel and fuel oil.

It is assumed that the construction fleet will use roughly 50te of fuel per day in total. Using generalised emission factors [Ref 1] and assuming vessels are using 1% sulphur fuel oil, this equates to the following approximate annual emissions:

- 3.0t NO_x;
- 4.0t CO;
- 163t CO_2;
- 1.0t SO_2;
- 0.2t hydrocarbons.

Discharges to water

Wastewater sources associated with the marine terminal construction will include:

- hydrotest water;
- sewage;
- rainwater accumulating at the tank farm facility;
- jetty loading arms and deck.

The largest single aqueous discharge will be from the hydrotest, which could be 4,300m^3 if both pipelines are discharged simultaneously.

Noise

Construction of the BTC Marine Terminal will encompass a variety of activities, which will potentially generate noise as follows:

- General civil works involved in constructing the tanks, general facilities and accommodation blocks will include the requirement for earth moving machinery, diesel generators, air compressors etc. In addition, blasting and piling may be required.

- Trenching and laying the loading line will involve specialist heavy equipment, including side boom cranes, as well as generators for welding equipment.

All construction activities will have associated noise from traffic relating to the delivery of materials and workforce. The management of traffic movement and the minimisation of disruption to communities within the vicinity of transportation routes will be addressed through provisions of the TMP (see Appendix C5).

Waste

Waste generated during the construction phase of the marine terminal will be dealt with in accordance with procedures set out in the Waste Management Plan (Appendix C3).

Table 9.5 provides a broad listing of the anticipated waste streams that will be generated by the construction of the Marine Terminal. The Waste Management Plan (Appendix C3) sets out a project strategy for quantifying, handling and disposing of the anticipated waste streams.

Table 9.5 Provisional Waste Inventory for BTC Marine Terminal Construction Phase

WASTE STREAMS	SOURCES	CLASSIFICATION (H or NH)*	MANAGEMENT OPTION	QUANTITY (TONNES)
Activated carbon	Spent fines from filtration systems	H/NH	Landfill	2
Aerosol cans	Empty containers, principally from personal use of deodorants and some chemical usage during construction	H	Pierce and recycle	0.5
Aluminium cans	Largely empty beverage cans	NH	Crush and recycle	20
Batteries Wet	Depleted cells used in vehicles and machinery	H	Recycle	1
Batteries Dry	Depleted cells used for personal stereos and other portable equipment, such as torches	H	Recycle	<0.5
Bitumen	Residues from road making. Mostly reused at the sites in road making	H	Incinerate	25
Black water				12,000
Bricks and building materials		NH	Landfill	6
Cables / copper	Off-cuts from construction of the facilities and temporary camps, plus removal during decommissioning	H	Recycle	<0.2
Cement dust		NH	Landfill	0.25
Chemicals	Spent chemicals and residues from all project phases, such as pipe coating, bleaches	H	Physical/chemical treatment; evaporate in drums; residue to landfill	TBD
Acids			Physical/chemical treatment; residue to landfill	TBD
Adhesives			Incinerate	<0.2
General Chemicals			Special treatment - disposal to a suitably licensed facility	3.5
Firefighting foam			Evaporate in drums; residue to landfill	0.2
Glycols			Evaporate in drums; residue to landfill	2
Solvents			Evaporate in drums; residue to landfill	0.2
Concrete / foundations	Deconstruction of facilities during reinstatement and site restoration	NH	Crush and use as building aggregate	10
Containers (large size)	Empty steel drums	NH	Recycle	TBD
Containers (other)	Empty steel and plastic containers or varying sizes	NH	Landfill	TBD
Contaminated water	Rainwater accumulating tank farm facility (approximately 7 storage tanks); from the jetty loading arms	H	Special treatment then discharge to sea via outfall	TBD
Contaminated wastes (waste oils etc)	Oil spillages and clean-up materials such as oil absorbers, grab packs and granules	H	Special treatment - disposal to a suitably licensed facility	TBD

WASTE STREAMS	SOURCES	CLASSIFICATION (H or NH)*	MANAGEMENT OPTION	QUANTITY (TONNES)
Dredged material (largely sand with some mud and silt)	Generated during construction of marine facilities, eg export jetty, breakwater, construction dock	NH	Due to the lack of any current marine industrial activity at the proposed jetty location, it is anticipated that such material will be uncontaminated. It is assumed that all dredged material will be discharged to sea in a designated dumping area subject to appropriate licence conditions by the relevant Turkish authority.	TBD
Drum cleaning waste	From cleaning steel drums of residual materials so that they may be re-used for other applications	H	Special treatment - disposal to a licensed facility	240
Electrical/electronic comps		NH	Landfill	<0.2
Electrical (eg switchgear)		H/NH	Landfill	<0.2
Exhaust catalysts			Landfill	<0.2
Filters air/oil	Spent filters from machinery and vehicles	H	Incinerate	0.25
Filters (water)		NH	Incinerate	0.75
Food	Scraps and other organic waste	NH	Incinerate	90
Diesel, Fuel and Oil Wastes	Oil absorbers, grab packs and granules	H	Incinerate	TBD
Diesel		H	Incinerate	3
Diesel generator lube oil		H	Incinerate	8
Misc oils (incl hydraulic)		H	Incinerate	0.75
Vehicle & equip lube oil		H	Incinerate	4
Glass	Empty bottles, largely from domestic use	NH	Recycle	100
Greases	Residues of lubricating products, plus some domestic greases	NH/H	Incinerate	TBD
Greywater				30,000
Hydrotest water	Discharges from hydrostatic testing of tanks pipelines (may contain chemicals, such as biocides and oxygen scavengers)	NH	Tested prior to discharge at a controlled rate to a site agreed with the MoE	160,000
Incinerator ash		H/NH	Landfill	120
Insulation	Offcuts from installation of insulation materials to piping and plant	H	Landfill	0.25
Light bulbs	Spent incandescent and fluorescent bulbs	H	Recycle - (fluorescent bulbs if in v. large quantities may require special treatment)	<0.1
Medical	Hazardous clinical waste, including sharps, needles, swabs, etc	H	Incinerate	<0.5
Packaging materials	Plastics, paper, cardboard, etc	NH	Recycle	TBD
Paint sludge		H	Incinerate	<0.5

WASTE STREAMS	SOURCES	CLASSIFICATION (H or NH)*	MANAGEMENT OPTION	QUANTITY (TONNES)
Paint and cans/brushes	Residues and discarded wastes from construction and maintenance activities, both oil and water based	H	Incinerate	<0.1
Paper and card	Wastes from office and domestic use	NH	Recycle/incinerate	90
Plastic bottles	Mostly discarded water containers and other domestic supplies; some industrial supplies	NH	Recycle	90
PPE and clothing	Discarded personnel protective clothing, overalls, boots, rags, etc	H/NH	Incinerate	3
Rags and oil absorbents		H	Incinerate	10
Refuse type wastes		NH	Incinerate	TBD
Sewage	Sewage from construction camps and temporary facilities	NH	Primary treatment of waste on site, then disposal of treated waste by appointed waste management contractor in agreement with local water authority	TBD
Sewage sludge	Hazardous residues from the sewage treatment facilities	H/NH	Special treatment - disposal to a suitably licensed facility	35
Steel	Offcuts from construction of pipelines and plants; removal of equipment during decommissioning	NH	Re-use - store useful components for future work and recycle remainder	150
Tyres	Worn discarded tyres from vehicles	NH	Recycle	<4
Washdown water	Runoff from cleaning vehicles, plant and other washing activities	H	Special treatment - disposal to a suitably licensed facility	80,000
Wood	Crates, pallets, sleepers, etc from supply of materials	NH		TBD
Timber		NH	Re-use	TBD
Trees, shrubs, branches		NH	Use as fuel (domestic etc)	TBD

* H = Hazardous; NH = Non-Hazardous

**Construction: Many waste streams that arise during construction of the marine terminal will be similar to those during pipeline construction. Those additional waste streams that are specific only to the marine terminal have been included. Pipe-specific waste (eg pipe bands, coatings etc) generated for the short length of pipeline from Terminal to Jetty has not been included, but will be less than 1% of that generated for the pipeline as a whole (see Table 5.1).

TBD – To be determined during ongoing engineering and Contractor selection.

9.8.3.2 Operational emissions, discharges and wastes

Marine-based emissions

Marine-based emissions of concern (ie those that have the potential to influence local air quality onshore) are those associated with the tanker emissions within the harbour, particularly while berthed. Atmospheric emissions from tankers' engine exhausts will be relatively minor and will be an intermittent source during operation. A modern tanker uses relatively little fuel while berthed. Given that the tankers are loading, rather than offloading oil, their fuel requirement will be even lower. Using typical emissions factors [Ref 5], and assuming both berths are in regular use, the anticipated annual emissions from tanker burning 1% sulphur fuel oil at the proposed facilities are as follows:

- approximately 22t NO_x;
- approximately 3t CO;
- approximately 1,200t CO_2;
- 7t SO_2;
- 1t hydrocarbons.

Land-based emissions

Anticipated operational emissions and discharges are as presented in Table 9.5.

Table 9.6 Operational Emissions/Discharges for BTC Marine Terminal

OPERATION	SOURCE	POLLUTANT	MANAGEMENT OPTION	QUANTITY
Emissions	tanker loading	CO_2 (Note 1)	EGF	152,450 te per year
	tanker loading	VOC	EGF	215 te per year
	tanker loading	NOx	EGF	36 te per year
	tanker loading	SO_2	EGF	387 te per year
	tanker traffic	NOx	untreated to atmosphere	22 te per year
	tanker traffic	CO	untreated to atmosphere	3 te per year
	tanker traffic	CO_2 (Note 1)	untreated to atmosphere	1,200 te per year
	tanker traffic	SO_2	untreated to atmosphere	7 te per year
	tanker traffic	hydrocarbons	untreated to atmosphere	1 te per year
Discharges	primary holding pond	treated wastewater	Irrigation and/or soakaway	24 m^3 per day

	general facilities	treated wastewater	Irrigation and/or soakaway	24 m^3 per day
	housing compound	treated wastewater	Irrigation and/or soakaway	38 m^3 per day
	Jetty	treated wastewater	Irrigation and/or soakaway	1.5 m^3 per day
	Guardhouse	treated wastewater	Irrigation and/or soakaway	1.5 m^3 per day
	Tankfarm	treated wastewater	Irrigation and/or soakaway	2 m^3 per day
Note 1: These CO_2 emissions have been used as the basis to determine total global warming potential expressed as CO_2 equivalent (CO_2-e) emissions in Chapter 16 (Cumulative Impacts).				

Noise

The main noise source from the operational BTC Marine Terminal will be the enclosed ground flare (EGF). Other sources are the transfer pumps located in the tank farm.

Waste

The waste arisings during the operational phase of the facility are the subject of ongoing detailed design and vendor selection for individual equipment items. Table 9.6 lists indicative types and quantities estimated from a number of sources. The Project is aware of the requirement to develop a waste inventory and to manage these wastes in accordance with the provisions of the Waste Management Plan (Appendix C3).

Table 9.7 Indicative Marine Terminal Operational Wastes (1)

TYPE	AMOUNT / YEAR
Domestic:	
• paper wastes	50 tonnes
• putrescible	40 tonnes
• glass	<25 tonnes
• plastic	<25 tonnes
• metallic	<25 tonnes
• textiles	<5 tonnes
• miscellaneous combustible	<25 tonnes
• miscellaneous non-combustible	<5 tonnes
• sewage sludge	<30 tonnes
• glack water	9000m^3
• grey water	21000m^3
Operational Terminal:	
• general waste suitable for landfill	3000 tonnes
• contaminated wastes (gloves, rags, absorbants etc)	<200 tonnes
• paper (office wastes)	<400 tonnes
• interceptor oil waste	<100 tonnes
• scrap metal wastes	<250 tonnes
• tank bottoms and cleaning	TBD

Shipping wastes (2) • oily sludge • oily bilgewater (average 15% oil content) • domestic waste • other (cargo associated) wastes	 TBD (2% of heavy fuel oil consumption) TBD (0.31m^3/1000tdw/month of operation) TBD (3.0kg/person/day) TBD (<0.01kg/day)
(1) Figures derived from multiple sources. (2) Ship generated wastes are enormously variable and linked to age of vessel, size of vessel, number of crew, days at sea since previous port call involving transhipment of waste to shore. Figures derived from 'A Waste Management Plan for Ship Generated Waste' prepared for Espoo Marine Committee, January 2000.

10 MARINE TERMINAL – ONSHORE BASELINE CONDITIONS

10.1 INTRODUCTION

10.1.1 Geographical context

The proposed BTC Marine Terminal is situated in southern Turkey on the coast of the Gulf of Iskenderun near Ceyhan. The location of the proposed BTC Marine Terminal is shown in Figure 10.1 below.

The BTC Marine Terminal development will consist of both onshore and offshore facilities (as described in Section 9). This section describes the onshore environmental and social baseline; the offshore baseline is dealt with separately in Section 11.

10.1.2 Objectives

The approach adopted for the environmental and socio-economic data collection was designed to fulfil the following objectives:

- to understand key environmental and social conditions in areas potentially affected by the BTC Marine Terminal;
- to provide data to enable the prediction and evaluation of potential impacts;
- to understand the expectations and concerns of a range of stakeholders (eg impacted communities, authorities and NGOs);
- to inform the development of mitigation measures;
- to provide a basis for monitoring (along with control sites) future change and assess the effectiveness of mitigation measures.

Figure 10.1 Geographical Context of the Proposed Marine Terminal

10.1.3 Sources of information and methodologies

Environmental and social baseline data were collected through combinations of desk studies, questionnaires and consultation with local people. To summarise, the key information sources included:

- Phase I and Phase II Habitat Surveys and Bird Survey Report;
- archaeological surveys;
- studies on geohazards, geology and geomorphology;
- contaminated land survey;
- air quality and noise surveys at the site and around it;
- on-site observations at the existing terminal;
- photography and landscape assessment from selected viewpoints;
- community meetings with local settlements;
- questionnaires administered with the Muhtar (or other key representatives) of each settlement (also referred to as the 'settlement level questionnaire');
- questionnaires administered at the household level (also referred to as the 'household level questionnaire').

Supplementary detail on the social questionnaires is provided in Appendix A4 and A5.

The results of the questionnaires provided a wide range of socio-economic data for the settlements surveyed. Some of the information collected is directly related to the predicted impacts of the BTC Marine Terminal (eg data on fishing as a source of livelihood enables an understanding of the impacts of decreased access to fishing grounds). Other data (eg information on land ownership or items owned by households) are essential for predicting and understanding changes to the overall 'balance of assets' in any particular settlement (see Box 10.1). These assets include natural capital (eg land, water), physical capital (eg transport, services), human capital (eg skills, education), financial capital (eg income, savings) and social capital (eg leadership and representation). It is this balance of assets that affects the ability of a settlement to cope with the changes brought about by the BTC Marine Terminal. If one asset within a settlement is lost (eg land), but other benefits are gained (eg employment), then the overall balance of livelihoods may remain the same. These different forms of capital (as found in the survey area) are described under each of the section headings, including a more detailed justification for why the data were collected.

Box 10.1 Livelihood Assets

The livelihood assets within any particular settlement can be grouped into the following forms of capital.

- **Natural capital:** land, water resources, livestock, fishing, aggregates, environmental quality etc.
- **Physical capital:** transport, communications, energy, housing, water and sanitation, schools, health facilities.
- **Human capital:** population numbers, skills, knowledge, ability to work, health, education.
- **Financial capital:** incomes, savings and credit, pensions.
- **Social capital:** leadership and representation, networks and groups, tolerance, access to wider institutions, ability to influence decision-making.

10.1.4 Study area

The study area for the onshore facilities is defined as:

- the permanent and temporary footprint of the onshore components of the terminal (tank farm, general facilities, transfer lines etc);

- the general immediate resources and communities that could potentially be affected by offsite impacts (noise, air quality, traffic, socio-economic benefits).

The wider coastal resources that could be impacted by an oil spill are discussed in Section 11.

The area encompasses a variety of natural and artificial habitats, including maquis, semi-natural and managed wooded areas, agricultural areas and landscaped gardens. These habitats are further discussed in Section 10.9.

Table 10.1 lists the nine settlements involved in consultation and questionnaire activities. Incirli, Karatepe and Karayilan are located in Ceyhan district and Sugozu, Hamzali, Haylazli, Deveciusagi, Golovasi and Sahil Sitesi in Yumurtalik district (see Figure 10.1*)*. These settlements can be divided into both neighbouring and non-neighbouring settlements. Neighbouring settlements have land directly adjacent to the existing BOTAŞ property and are most likely to be the primary receptors of impacts associated with the BTC Marine Terminal. These receive priority focus in both the baseline section and in the subsequent assessment of impacts. Conversely, non-neighbouring settlements are defined as those whose land is not adjacent to the BTC Marine Terminal. The latter are located between 1km and 30km from the BTC Marine Terminal.

Table 10.1 Summary Table of Household Surveys

	Distance from BOTAŞ Boundary Fence (approx.)	TOTAL POPULATION	TOTAL NO. OF HH*	NO. OF HH SURVEYED	TOTAL POPULATION IN RESPONDENT HHS	% OF POPULATION SURVEYED
Neighbouring Settlements						
Golovasi	1.5km west	1710	450	26	127	7.4
Sahil Sitesi**	<1km west	Not available	150	8	9	-
Incirli	<100m east	500	100	23	103	21
Karatepe ***	<100m north	500	80	30	127	25
Non-Neighbouring Settlements						
Sugozu	6km southwest	1150	300	25	90	8
Hamzali	5km west	500	100	23	98	20
Haylazli	24km southwest	1000	160	30	127	13
Deveciusagi	28km southwest	900	244	30	154	17
Karayilan****	1km north	Not available	Not available	5	-	-

* HH = households
** Some settlements in Turkey have multiple units with a central core *(koy)* and one or more hamlets *(mezras).* Sahil Sitesi is a small precinct of Golovasi, primarily used in summer by secondary homeowners. The population of Sahil Sitesi is difficult to ascertain because most people live in the settlement only during the summer months.
*** Karatepe is one of three settlements of the municipality of Kurtpinari.
**** Karayilan is also a settlement within Kurtpinari Municipality. It does not have its own Muhtar. No information is therefore available from the *settlement level questionnaire*.
Source: [Household Survey and Settlement Level Survey]

10.1.5 Section contents

The onshore environmental and social baseline aspects at, and in the vicinity of, the proposed BTC Marine Terminal site are described under the following headings:

- Climate and Meteorology;
- Landscape;
- Soils;
- Geology and Geohazards;
- Surface Water and Groundwater;
- Biological Environment;
- Air Quality;
- Noise;
- Cultural Heritage;
- Demographic and Migration Patterns;
- Land Ownership and Use;
- Livelihoods, Employment and Skills;

- Infrastructure, Utilities and Services;
- Attitudes and Perceptions towards the BTC Marine Terminal.

10.2 CLIMATE AND METEOROLOGY

10.2.1 General

The climate of Turkey is classified as 'warm temperate' with a number of variations. The study area experiences a typical Mediterranean climate with warm wet winters and hot dry summers with little or no rainfall from May to September [Ref 1]. The Taurus Mountains in the north shield the area from the more extreme climatic elements inland.

10.2.2 Temperature

The mean annual temperature at Ceyhan is 17.8 ºC. In the winter months the Mediterranean Sea moderates the climate resulting in warmer winters [Ref 2] than inland. The lowest temperature recorded at Ceyhan was –11.3 ºC.

Ground frost in the region is infrequent and limited to the upper 20 cm of soil. Soil temperatures at Ceyhan do not generally drop below 0 ºC, with temperatures recorded close to the soil surface (5 cm depth) of 2.9 ºC [Ref 3]. At Ceyhan itself, ground frost has never been recorded.

More comprehensive meteorological data are available for two coastal stations at Iskenderun approximately 60km south-east of the proposed BTC Marine Terminal location and at Yumurtalik, 30km to the south-west (see Plate 10.1).

Table 10.2 presents the long-term monthly average temperatures published by the General Directorate of Meteorology between 1939-1990 for Iskenderun station and between 1964-1990 for Yumurtalik station [Ref 1].

Table 10.2 Monthly Average Air Temperature in the Iskenderun Region (ºC)

	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC
Iskenderun												
Average	11.7	12.5	14.7	18.4	22.0	25.3	27.8	28.4	26.6	22.1	17.5	13.4
Maximum	15.4	16.3	18.7	22.3	25.5	28.4	30.4	31.3	30.1	26.8	22.0	17.4
Minimum	8.2	8.9	10.8	14.2	17.8	21.6	24.5	25.1	22.7	18.2	13.9	10.1
Yumurtalik												
Average	10.2	10.9	13.3	17.0	20.7	24.0	26.8	27.3	25.4	21.1	15.9	11.8
Maximum	15.0	15.8	18.2	21.6	24.7	27.6	30.0	30.9	30.4	27.2	21.6	16.8
Minimum	5.9	6.4	8.8	12.3	15.6	19.2	22.4	22.7	20.2	16.2	11.4	7.6

Table 10.2 indicates that there is little variation between the two locations at different times of the year and that the data are probably representative of the terminal location. Iskenderun has a slightly higher mean average monthly temperature.

10.2.3 Precipitation and humidity

There is a large variation in the total annual rainfall between the coastal plain and the mountainous region to the north of Ceyhan. Total annual precipitation in the coastal plain is approximately 670mm. There is little variation between monthly and daily maximum rainfall at Iskenderun and Yumurtalik (see Table 10.3).

Table 10.3 Monthly Average and Daily Maximum Rainfall (mm) in the Iskenderun Region

	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC
Iskenderun												
Total Monthly Average	106.7	91.6	90.4	63.8	46.2	26.0	5.5	15.8	34.5	93.4	77.2	98.5
Max daily	89.5	60.2	96.1	83.4	72.7	114.4	38.8	54.6	60.9	82.6	126.9	155.3
Yumurtalik												
Total Monthly Average	125.4	93.9	86.7	62.8	64.5	19.6	9.7	6.7	17.0	75.2	90.3	118.1
Max daily	75.0	71.8	54.4	67.7	210.8	43.8	43.8	32.7	113.8	120.4	113.2	74.6

Note: These values are long-term averages over a 60-year period.
Source: [Ref 2]

Rainfall is highest in the winter months between November and March. Monthly winter rainfall averages 93mm for Iskenderun and 103mm for Yumurtalik. Rainfall during the summer months drops to less than 10mm at both Iskenderun and Yumurtalik. Rainfall intensity within this region was measured as 110mm hr^{-1} [Ref 2].

Snow is confined to the upper slopes of the Taurus Mountains to the north of the BTC Marine Terminal and is not experienced in the coastal zone.

10.2.4 Wind

Winds are light, averaging 1.5-2.0m s^{-1}. They blow from the north-east off the Taurus Mountains for the majority of the year (see Figure 10.2). The wind changes to a westerly direction in April, which is associated with a strengthening of sea breezes. During the summer months (from June through to September), the prevailing wind direction is south to south-west. Wind speeds increase to a brisk 2.1-4.3m s^{-1} in the summer months, before reverting back to a northerly direction in the winter.

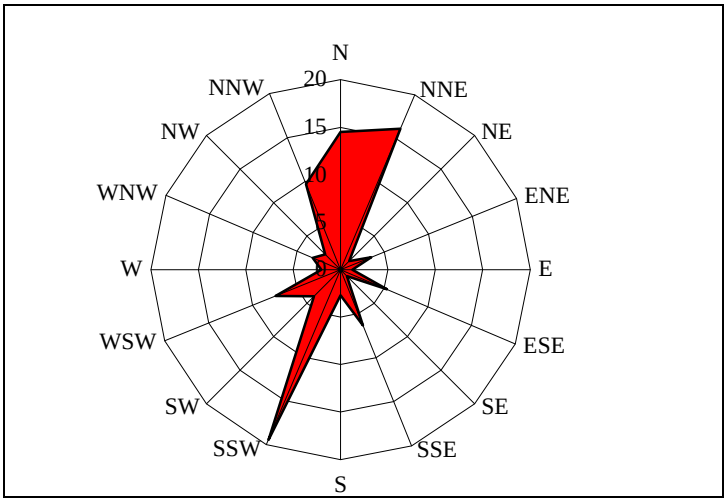

Figure 10.2 Annual Wind Rose
[Source: Yumurtalik Meteorological Station, 1996**]**

10.2.5 Fog and visibility

The monthly average foggy days (defined as visibility less than 1,000m) for Iskenderun and Yumurtalik meteorological stations are provided in Table 10.4. Limited data are available for both of these stations, although it is apparent that the fog is rare in the region and visibility is generally good all year round.

Table 10.4 Monthly Average Foggy Days in the Iskenderun Region

10.3 LANDSCAPE

10.3.1 Topography

The proposed BTC Marine Terminal facilities will occupy an area ranging from approximately 125m to 3m above sea level and is located adjacent to an existing marine terminal complex, operated by BOTAŞ.

The general topography of the proposed BTC Marine Terminal site is characterised by a flat plateau interspersed with hills and some low eroding cliffs. The topography between the proposed marine terminal and the new jetty is characterised by south to south-westerly facing slopes. These slopes descend from 100m in height to chart datum over a distance of less than 1km (see Figure 10.3),[Ref 3].

Much of the existing tank farm at the north of the marine facility is situated on a plateau at a height of between 100-120m. The proposed tank farm will be located up-slope from the existing site, at a height of approximately 125m. The new accommodation and general facility areas will lie to the south of the tank farm, occupying approximately 7.6ha and 1.7ha, respectively.

10.3.2 Landscape character

10.3.2.1 The foreshore

The foreshore and beach area already have an industrial character due to the existing BOTAŞ jetty and associated facilities. The jetty is visible from over a relatively large area, as is the associated tanker traffic. Further human activity is apparent from the presence of coastal fishing settlements such as Sahil Sitesi and Golovasi (see Plate 10.1).

Plate 10.1 View of Existing Jetty from Proposed General Facilities Area

Figure 10.3 Aerial Photograph of the Existing BOTAŞ Marine Terminal

The coast is predominantly made up of a series of small rocky headlands, interspersed with small sand beaches (particularly on the southern side of the headlands). The land rises steeply away from the coast, and is mostly sparse scrub. Sand dunes are located along the coast of the existing terminal site between the existing jetty and the location of the proposed jetty.

Long distance views in both directions are limited due to the undulating coastal strip and existing jetty. Inland views are restricted due to rising high ground. The existing jetty is clearly visible from the coastal settlement of Sahil Sitesi where a number of secondary homeowners are resident.

10.3.2.2 Terrestrial landscapes

The terrestrial landscape is gently undulating. The terrain rises from the foreshore to the existing BOTAŞ tank farm, located on high ground, with maquis (scrub) and orchards providing a varied aspect to the surrounding areas. The tank farm is the dominant feature from most aspects, as it is situated on the highest ground on the seaward side of the broad Kalebogazi valley, which separates the terminal from the settlements of Narlik and Kurtkulagi (see Plate 10.2).

Plate 10.2 View of Kurtkulagi from the Proposed Tank Farm Site

Other components of the existing terminal complex contribute significantly to the landscape character, particularly the accommodation blocks. These, and other general facilities, are located on a gentle slope south of the tank farm, interspersed with landscaped gardens and stands of managed woodland. The accommodation buildings stand out by virtue of their height, and are clearly visible from the site of the proposed new general facilities along the coast to the south (see Plate 10.3). These facilities are, however, screened from inland views by a series of low rounded hills running broadly parallel to the coast, (approximately 130m above sea level). Scrub vegetation covers much of the slopes of these hills.

Plate 10.3 View of Existing Facilities from Proposed Accommodation Area

10.4 SOILS

10.4.1 General

The proposed BTC Marine Terminal site is formed of basalt and flysch units, overlain by the soil mantle. This soil mantle is represented by colluvium, topsoil and artificial fill in the tank farm area and solely by colluvium in the general facilities area [Ref 4 and Ref 5]. Colluvial deposits are likely to be derived from neighbouring rock formations and mainly composed of clayey sandy gravely cobbles/boulders and gravely clayey sand. Soil thickness at various locations on the site varies between 1m and 5.75m [Ref 4 and Ref 5].

10.4.2 Soil erosion and agricultural soil quality

10.4.2.1 Soil erosion

Areas of soil erosion at the proposed BTC Marine Terminal have been taken from erosion classifications used in the General Directorate of Rural Services (GDRS) erosion maps, which are derived from the Soil Survey Manual of Turkey. These erosion classes are defined in Section 5.4.4.

There are no areas of extreme or severe erosion within the proposed BTC Marine Terminal site (see Figure 10.4). A small area of severe erosion exists to the north of Karatepe settlement. Furthermore, there has been no history of subsidence or erosion during the 25 years that the existing BOTAŞ Marine Terminal has been in operation [Ref 6].

10.4.2.2 Agricultural soil quality classification

Agricultural land in Turkey is classified according to the extent to which its physical or chemical characteristics impose long-term limitations on agricultural use for food production [Ref 6]. Section 5.4.9 (Table 5.6) provides definitions for the GDRS soil capability classes.

Two areas of soil capability Class II exist to the east of the existing BOTAŞ Marine Terminal, one of which slightly extends into the north-eastern corner of the site and will be crossed by the loading line route (see Figure 10.4). Areas of soil capability Classes III and IV, (ie possessing some form of agricultural activity), and soil capability Class VII, (ie with no economical agricultural purpose), exist within the existing BOTAŞ Marine Terminal site boundaries.

10.4.3 Soil contamination

Chemical analysis of soils at the proposed BTC Marine Terminal site was carried out for Total Petroleum Hydrocarbons (TPH), nickel (Ni), arsenic (As), cadmium (Cd), chromium (Cr), lead (Pb), mercury (Hg) and vanadium (V) [Ref 7]. Table 10.5 provides soil sample information while Table 10.6 presents the hydrocarbon analysis results for the soil samples and Table 10.7 shows the metal analysis results.

Table 10.5 Soil Sample Information

Sample No	Easting	Northing	Location	Sampling Point	Date	Time	Depth (cm)
S1 S2	0760149	4087155	CMT Tank 7	SP1	28/07/02	17:00	10-20
S3 S4					28/07/02	17:00	25-35

Table 10.6 Hydrocarbon Analysis Results for Soil Samples

Location	Sampling Point	Sample No	Concentration (mg/kg)*					
			Benzene	Toluene	Ethyl benzene	Xylene	DRO	GRO
CMT Tank 7	SP1	S1	<0.02	<0.02	<0.02	<0.02	97	<1
		S3	<0.02	<0.02	<0.02	<0.02	153	<1

* < indicates that the concentration is below the method detection limit.

Table 10.7 Metals Analysis Results

Location	Sampling Point	Sample No	Concentration (mg/kg)[1]						
			As	Cd	Cr	Pb	Hg	Ni	V
CMT Tank 7	SP1	S2	2.30	0.200	143.00	10.10	0.023	179.00	102.00
		S4	2.50	0.021	148.00	10.40	0.021	172.00	106.00

The study results showed that concentrations of As, Cd, Pb, Hg and V at the sampling sites (S1 – S4) are below the established international guideline values and Turkish standards[1]. Vanadium concentrations at the CMT tank 7 sampling locations were relatively higher than that of the other sampling locations, but still remain lower than the relevant standards.

[1] Turkish Regulation for Control of Soil Pollution (Ref: Official Gazette, 10.12.2001

Total chromium levels were above Canadian agricultural and residential guideline values[1] as well as above Turkish standards for S2 and S4. Chromium concentrations in all of the samples are below the Dutch guideline[2].

The nickel concentrations for all the samples were above the Canadian guideline values. Since pH of the soil samples was measured above 7 and the majority of soils found in Turkey are basic (ie pH above 7), the Turkish soil quality standards for the basic soils are likely to be applicable for the soil types encountered within this project. In this regard, a nickel standard of 112.5mg/kg is used in this report to evaluate the soil analysis results. The nickel concentrations for the S2, S4 samples were above the Turkish soil quality nickel standard of 112.5mg/kg.

The relatively high concentrations of chromium and nickel found in the soil samples are indicative of some form of past contamination due to the partially high TPH results. Further, partially high vanadium concentrations, which are also an indicator of petroleum contamination, were found in the samples.

DRO concentrations in the samples were higher than the Canadian agricultural and residential guideline values of 100mg/kg.

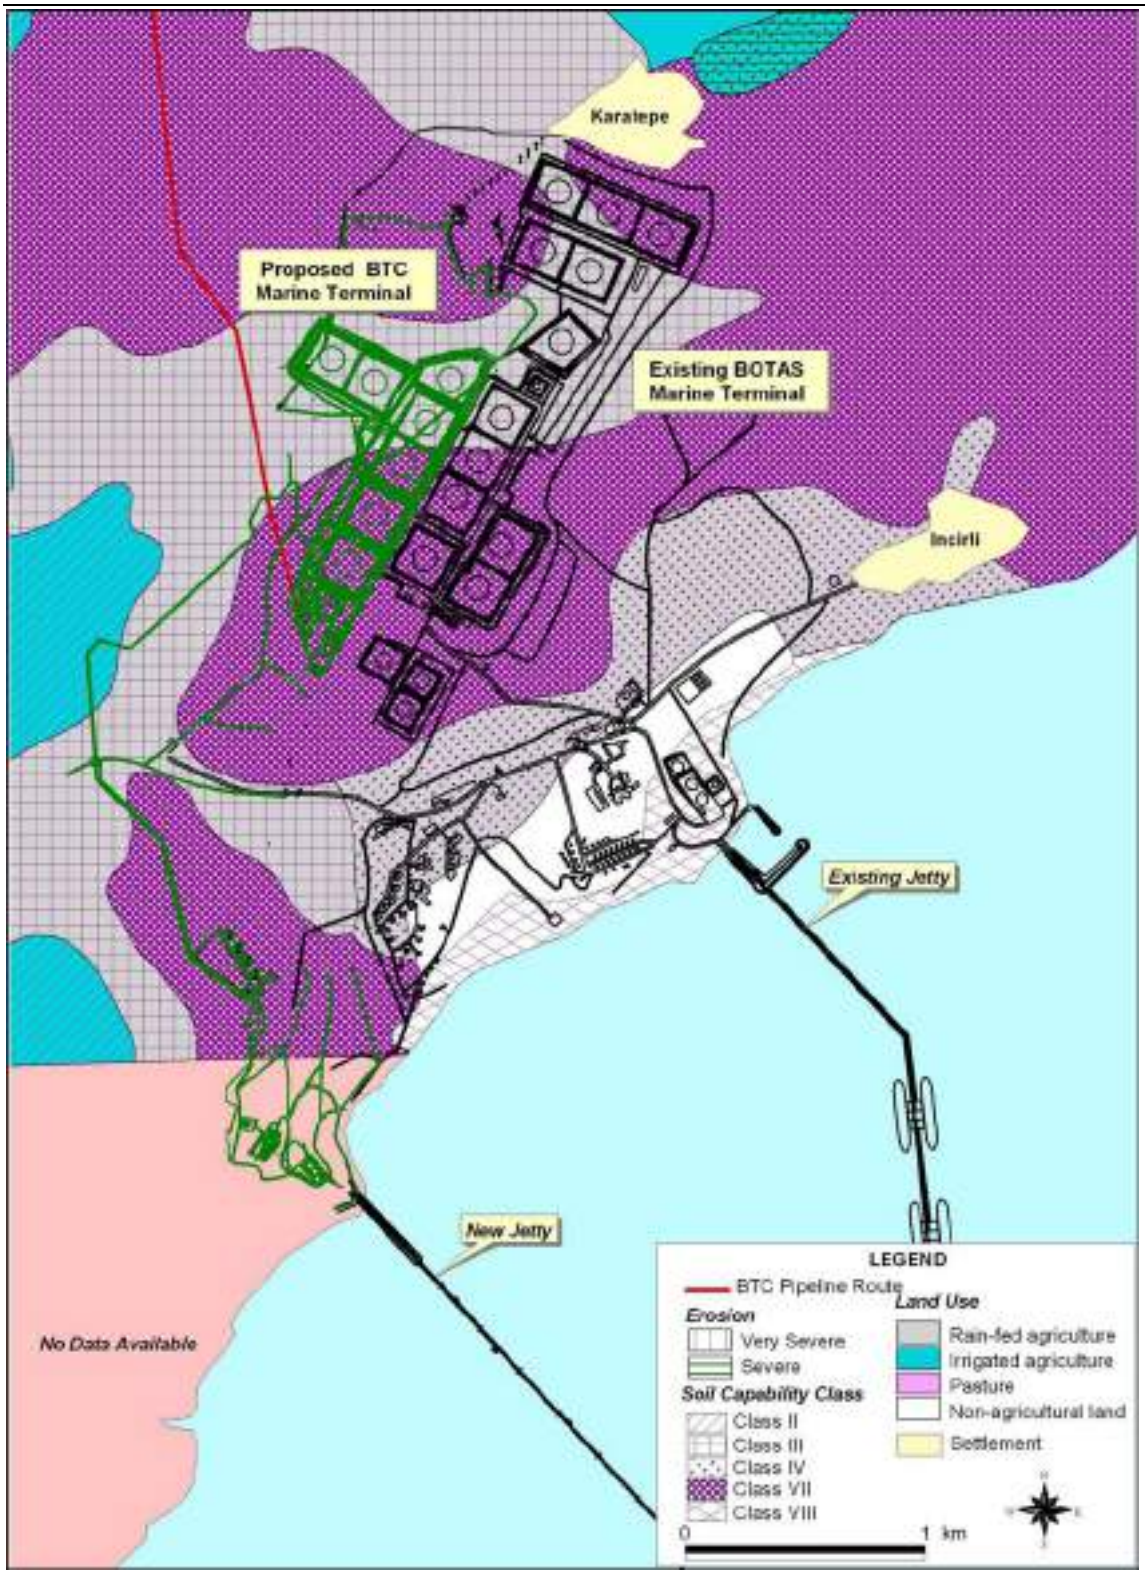

Figure 10.4 Soil Capability and Erosion Areas at the Proposed Marine Terminal Site

10.5 GEOLOGY AND GEOHAZARDS

10.5.1 Solid geology

The Cukurova basin is one of the major sedimentary basins in this region of Turkey and is bounded by the Amanos Mountains on the east, the Ecemis Fault Zone to the west, the Taurus Mountains to the north and the Mediterranean Sea to the south. It is divided by the Misis-Kyrenia fault that runs parallel to the coast into the Adana basin to the north and the Iskenderun basin to the south (see Figure 10.5). The BTC Marine Terminal is located on the Iskenderun basin [Ref 1].

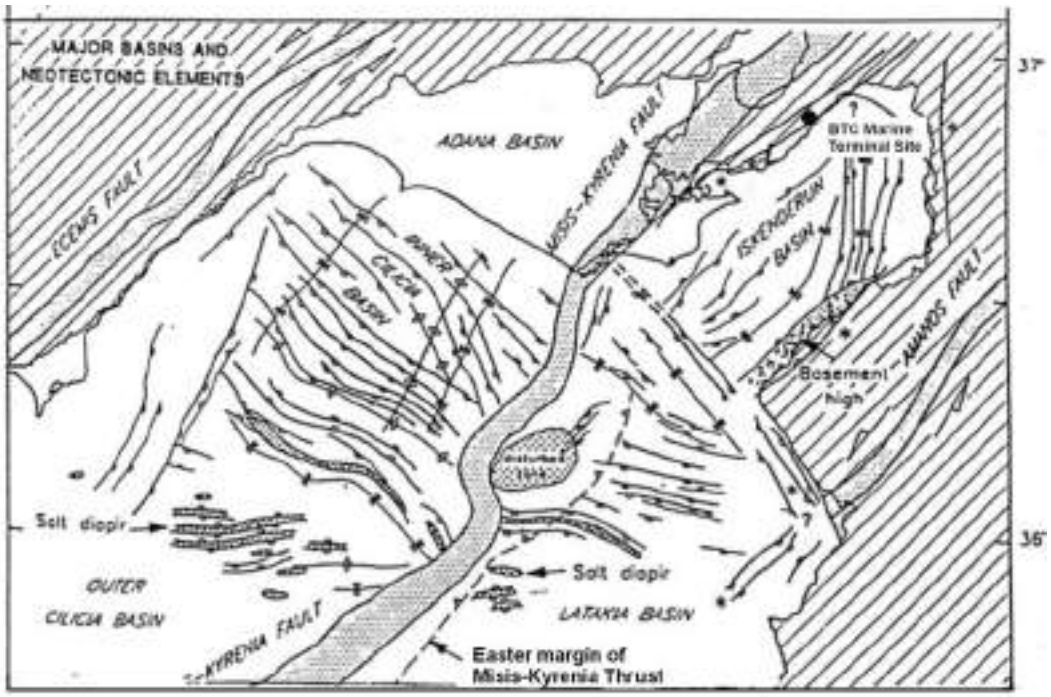

Figure 10.5 Major Geological Basins [Ref 1]

The geological sequence encountered in the vicinity of the proposed terminal is shown in Figure 10.6. This indicates that the area comprises early to middle Miocene clastic rocks, dominated by Karatas and Kizildere formations [Ref 8]. The Karatas formation, which extends north and south-west of the proposed BTC Marine Terminal, is composed of sandstone, sandy limestone, marl, limestone, siltstone and gravels. This is the oldest rock unit in the vicinity of the terminal. In contrast the Kizildere formation is located further west stretching along the coast to Yumurtalik. This formation is composed of sandstone, gravely marl and clay limestone.

Geological and geomorphological studies conducted at the existing BOTAŞ Marine Terminal indicate that it is located on volcanic rock, which is pyroclastic and basaltic in origin [Ref 8] (see Figure 10.6). The basaltic component was observed as lava plateaus with a flow direction to the north of the marine terminal. These lava flows vary in thickness, between 5m and 20m, but on occasion reaching up to 100m. They are dark grey to black in colour and often include gas.

Pyroclastic rocks were observed in two forms, as bedded lower pyroclastic rock and as tephra [Ref 8].

1. Lower pyroclastic rocks are Quaternary aged rocks and were observed throughout much of the area of the Marine Terminal study area. These rocks are composed of basaltic tuff, ash, lapilli, volcanic sand, local volcanic sandstone, clay and marl sequences and are usually poorly cemented and friable.

2. Tephra rocks are interbedded pyroclasts found predominantly near volcanic cones. Geological studies indicate the presence of this type of rock around Ceylan Hill [Ref 8] (see Figure 10.6). These rocks comprise yellow, red, brown and black coloured basaltic slag, tuff, ash, lapilli, volcano bomb, breccia and sand.

Further west of the existing Marine Terminal, alluvium material is present along Boyali Creek Valley, composed of unconsolidated silt and mud drained from the catchment area [Ref 8].

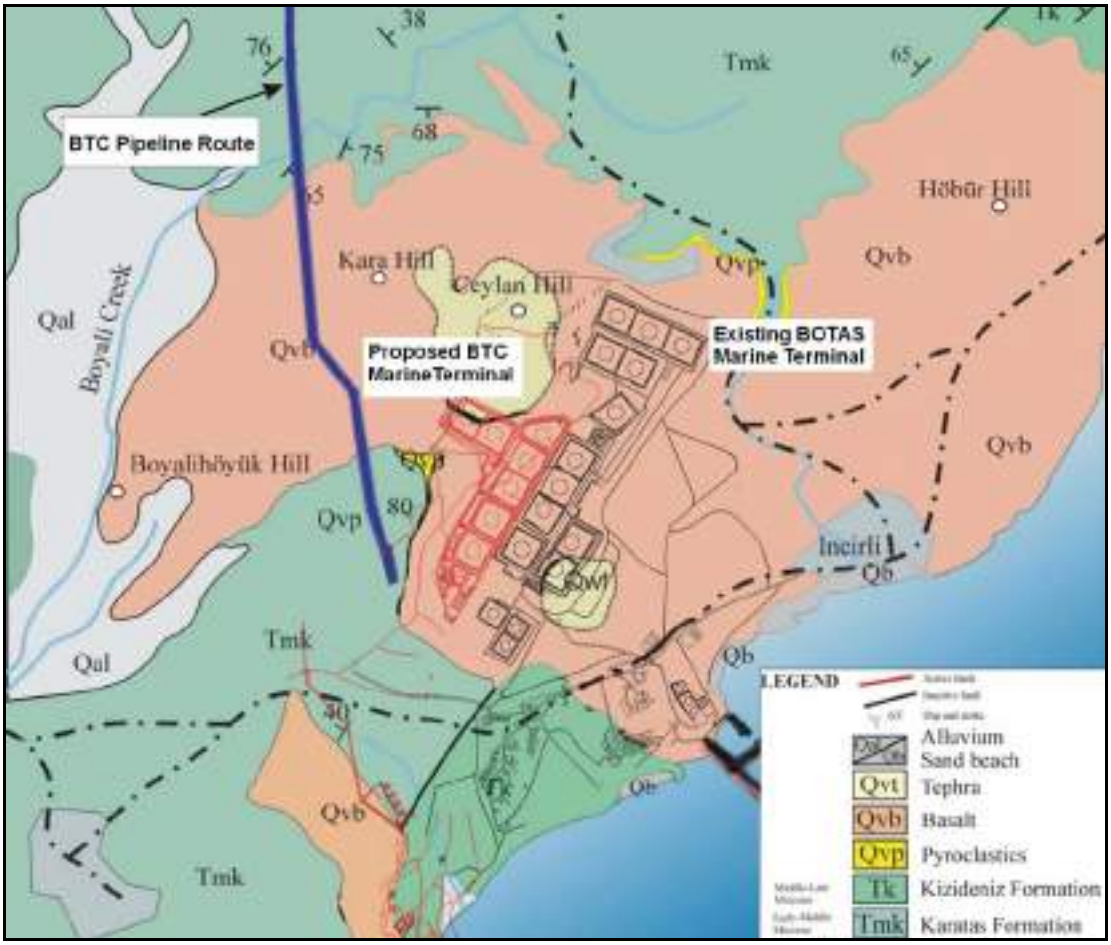

Figure 10.6 Geological Map of the BTC Marine Terminal Area

10.5.2 Landforms

Landforms of the area between the Misis Mountains and Iskenderun Bay are strongly influenced by the tectonic zones and bedding orientations in the sedimentary rock units [Ref 8]. Morphological features in the area of the existing BOTAŞ Marine Terminal include alluvium filled valley floors and depressions, which are elongated between eroded high land (see Figure 10.7).

Elevated topographical features in this area are formed by volcanic structures. Volcano cones are responsible for the formation of Kazankaya Hill, Ceylan Hill, Hoyuk Hill and north Incirli

[Ref 7]. These cones are of various sizes with slope gradients between 20-35°. There are no obvious craters on these cones.

Basalt lavas that spread out from volcanic cones have formed features such as lava plateaus and flows in the marine terminal area [Ref 7]. The proposed location for the tank farm is the flat area to the south of Ceylan Hill, which is identified as a lava plateau (see Figure 10.8). The basalts originate from the Kara Hill Volcano to the north of the site. Boyali Hoyuk and Uzunsirit lava flows are the longest lava flows in the vicinity of the BTC Marine Terminal study area, reaching up to 2km in length [Ref 7].

Alluvial sediments in the vicinity of the proposed BTC Marine Terminal were observed along Boyali Creek Valley to the north-west and west of the site [Ref 7]. Boyali Creek flows in a very narrow and shallow channel on these sediments, suggesting that the alluvial flats were formed as floodplains.

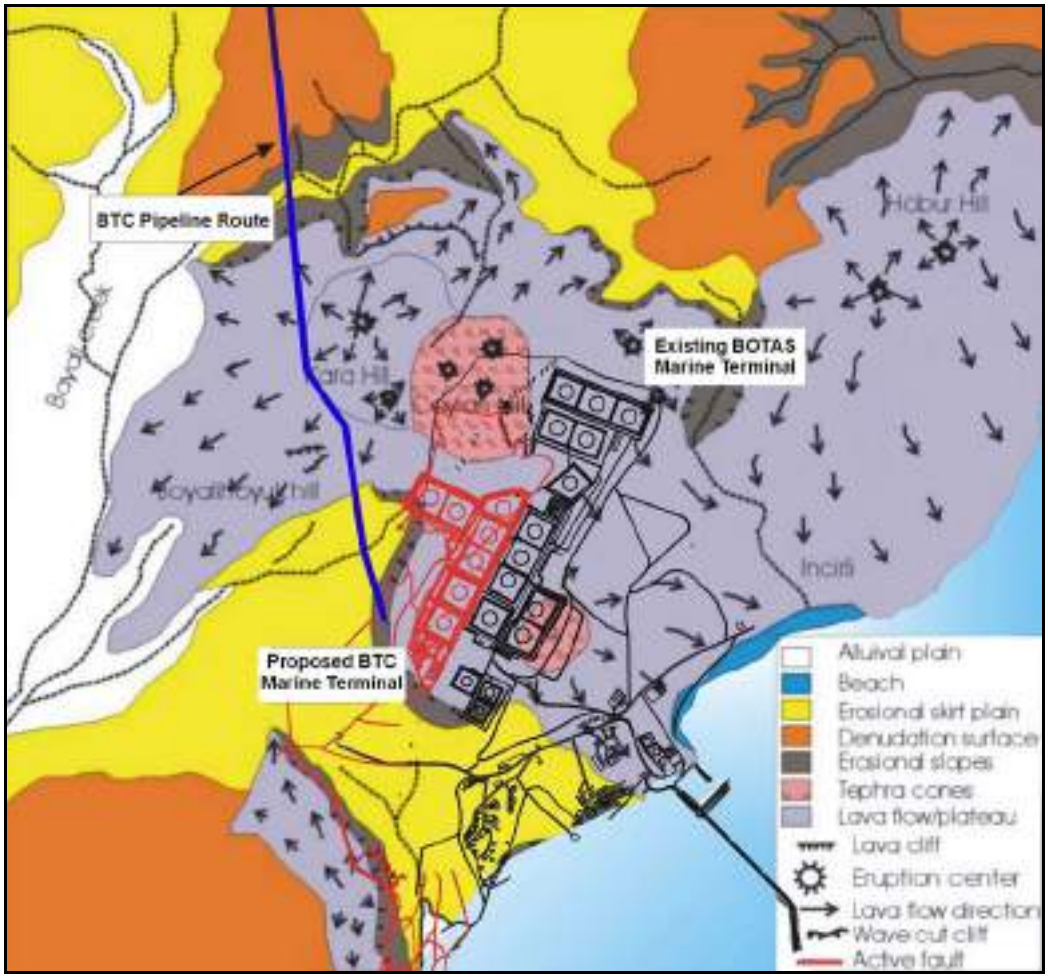

Figure 10.7 Landforms of the BTC Marine Terminal Area (ILF 2001)

10.5.3 Geohazards

10.5.3.1 Seismic activity

The BTC Marine Terminal will be located in a seismically active region of Turkey, between two faults, the Yumurtalik Fault and the Osmaniye-Karatas Fault (see Figure 10.8). These faults extend along the Misis Mountains. Study of the aerial photographs revealed that volcanic activity was associated with the NNE-SSW trending normal faults, which belong to the Osmaniye-Karatas and Yumurtalik Fault system [Ref 6].

Yumurtalik Fault is within the Osmaniye-Karatas Fault zone and extends between Karagedik and Yumurtalik [Ref 6]. The Yumurtalik Fault is not a continuous fault and consists of a number of small segments and/or parallel segments. It is a B-class[1] fault, approximately 62km long, and trenching studies indicate that it is an active fault showing one Holocene activity, (ie one activity during the last 10,000 years). Side scan sonar results and trenching studies have confirmed that the Yumurtalik fault will not be crossed by the new tank farm or the new jetty [Ref 9]. The Osmaniye-Karatas fault was identified as an inactive fault during trenching studies [Ref 9].

10.5.3.2 Earthquakes

The Adana region is known to be seismically active. The region has experienced 101 earthquake events in the last 2,000 years [Ref 1]. However, because of the short length of the faults in the region, large earthquakes (magnitude, M>7) are not historically known or expected [Ref 11]. These large earthquakes have not been recorded along the East Anatolian Fault on the eastern coast of the Gulf of Iskenderun and along the Dead Sea Fault (north-east of the gulf). Therefore, the risk of occurrence of a large earthquake near the proposed BTC Marine Terminal is minor [Ref 9].

Several earthquakes with M<7 have been recorded and have caused damage in the area (Celebi, 1999). These earthquake events have had varying intensity, magnitude and duration. Locations of earthquakes recorded in the region between 1900 and 1996, with a magnitude of ≥4.0, were obtained from the General Directorate of Disaster Affairs Earthquake Research Department [Ref 6] (see
Figure **10.9**).

In more recent years, two notable earthquakes occurring in 1945 and 1998 resulted in widespread destruction (see Figure 10.10). The 1998 earthquake occurred in the Adana basin in the districts of Adana and Ceyhan and was the last to occur in this region. The epicentre of the 1998 earthquake occurred 30km away from the proposed BTC Marine Terminal, (depth approximately 22km; M=6.3), causing considerable damage, with a total of 144 deaths [Ref 9]. However, due to the distance of the epicentre and the size of the earthquake, no damage was detected to any structures at the existing BOTAŞ Marine Terminal. The left-lateral fault that caused the earthquake is called the Misis-Ceyhan Fault.

[1] B-Class Fault: faults with indications of Holocene activity. Possible and probable displacements of centimetres to meters.

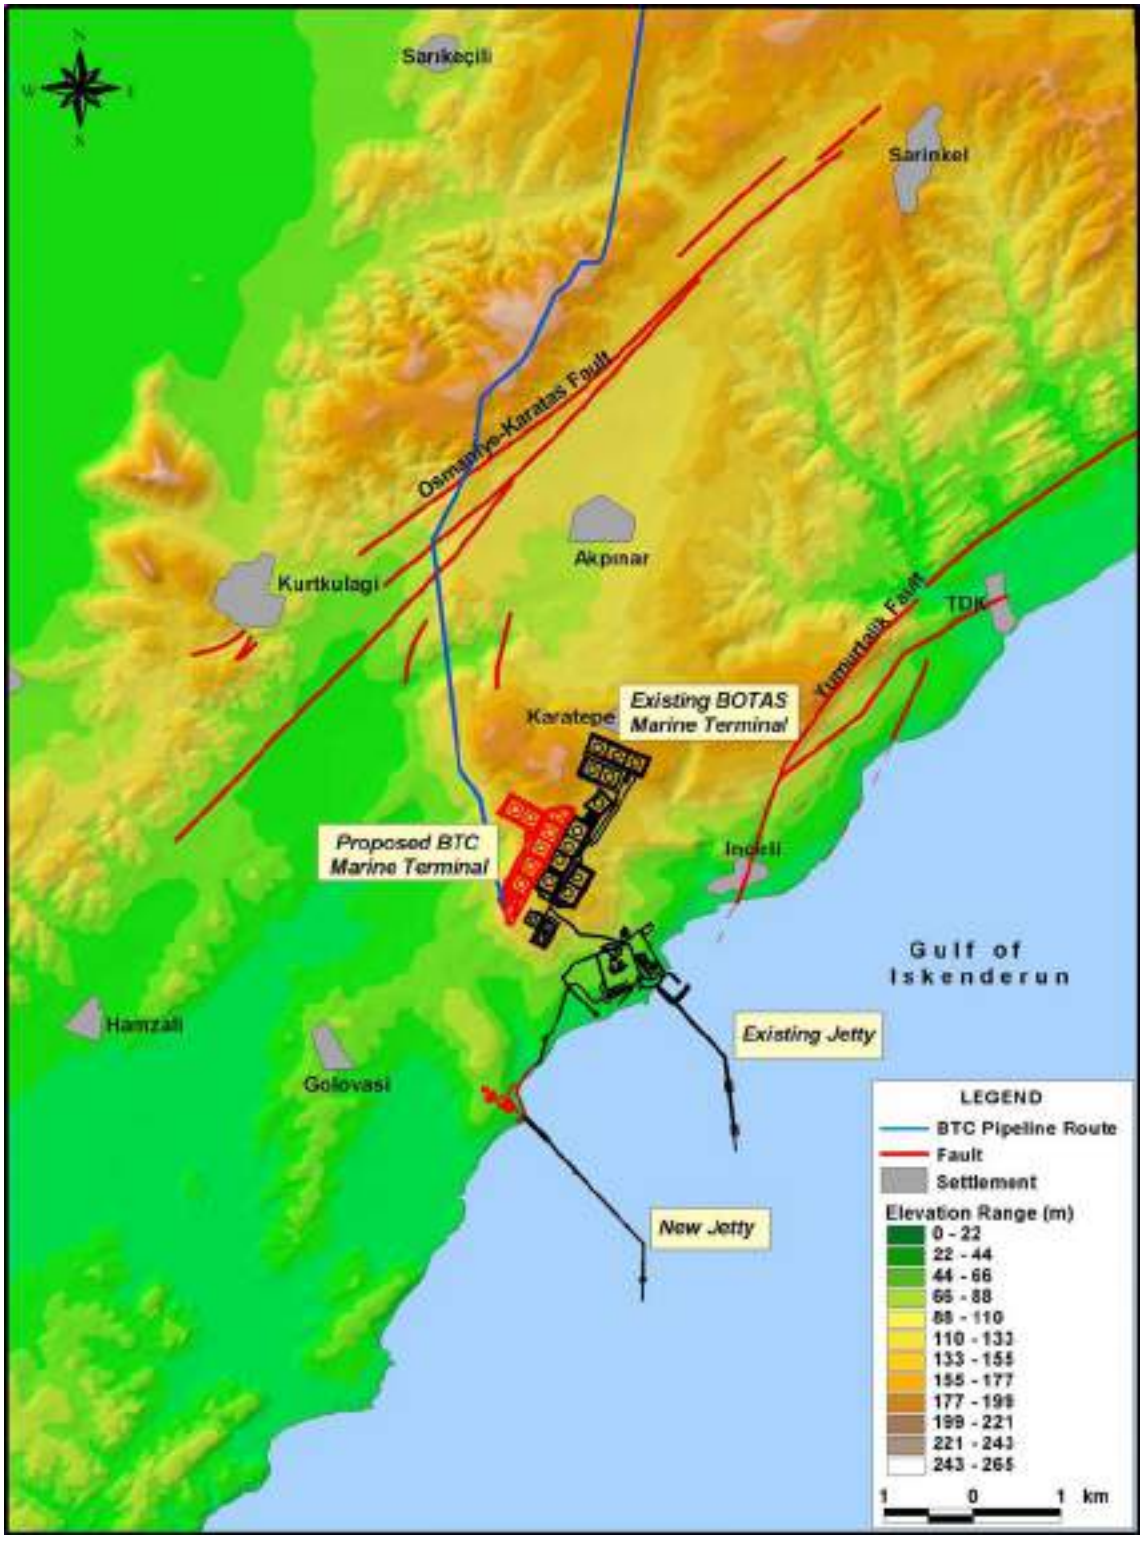

Figure 10.8 Major Faults in the Area of the Proposed BTC Marine Terminal [Ref 1**]**

Figure 10.9 Locations of Earthquakes (M≥ 4.0) in the Adana Basin between 1900 and 1996 [Ref 6**]**

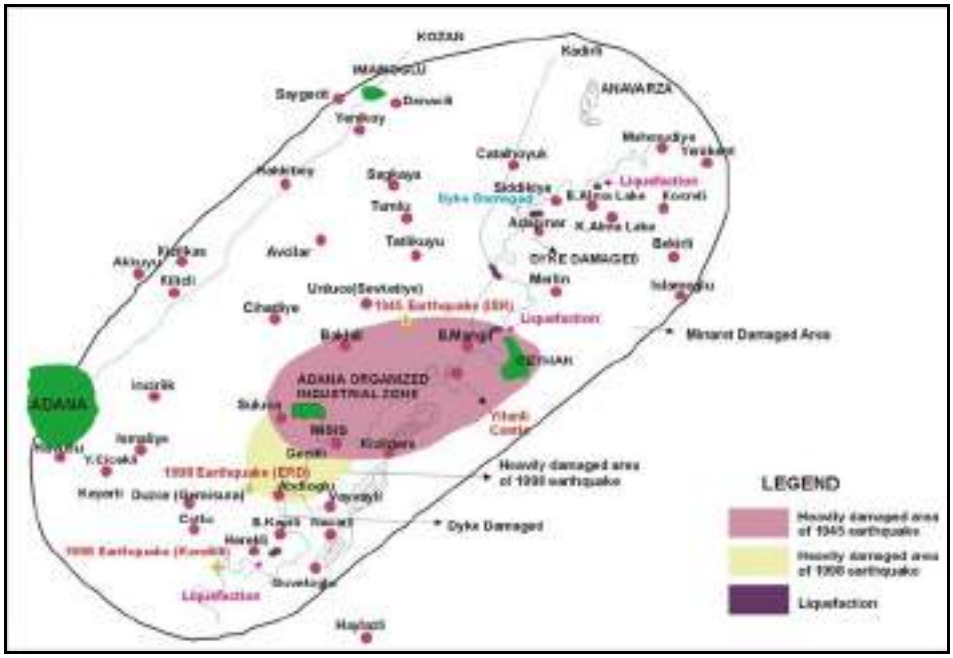

Figure 10.10 Damage Distribution Map of the 1945 and 1998 Earthquakes [Ref 1**]**

10.5.3.3 Volcanoes

There are 13 inactive volcanoes that exhibit Holocene activity in Turkey, though the closest to the proposed terminal, Erciyes Dagi-Stratovolcano, is approximately 190km away [Ref 9]. A stratovolcano comprises alternating layers of lava flows and volcanic ash, exhibits explosive eruptions during which ash may be carried thousands of miles. In general, this type of volcano erupts episodically over tens to hundreds of thousands of years and therefore has a low probability of occurrence [Ref 9]. There have been no volcanic eruptions in Turkey in the last 100 years [Ref 10].

The topography of the BTC Marine Terminal site was formed by volcanic structures within the Quaternary basaltic volcanism, which are inactive volcanoes [Ref 9]. Both Kara Hill and Ceylan Hill are old inactive volcanoes within the vicinity of the proposed site.

The greatest volcanic hazard that may arise at the proposed BTC Marine Terminal site is from ash fall. However, as the dominant wind direction at the site is from the north-east in the winter and SSW in the summer (see Section 10.2.4), the marine terminal is not situated downwind of any stratovolcanos. The risk of damage to the proposed BTC Marine Terminal as a result of volcanic activity is therefore expected to be negligible [Ref 9].

10.5.3.4 Landslides

The potential for mass movements, such as landslides, as a result of seismic forces acting on the lava cliff around the new tank farm and at the slopes of Ceylan Hill were investigated during geotechnical studies undertaken in 2001. Both field observations and slope stability calculations suggest that the potential for landsides at the proposed BTC Marine Terminal facilities is low [Ref 9 and Ref 4].

Geohazard studies also undertaken at the proposed BTC Marine Terminal site indicate that rock falls and block rolls are widespread on cliffs surrounding the lava plateau to the southwest of the proposed tank farm and to the north-east of the proposed housing compound [Ref 8]. Observations suggest that block rolls occur according to the position of fractures on the lava

[Ref 9]. The size of these rocks and stones can vary from a few centimetres up to a few metres. However, geohazard studies conclude that the risk of damage to the proposed BTC Marine Terminal due to landslides is expected to be minor [Ref 9].

A further detailed landslide hazard study investigated the two identified potential landslide hazards at the south-west corner of the new tank farm and at Ceylan Hill (north-east of the new tank farm) [Ref 13]. This study identified one shallow old landslide area at the south-west corner of the new tank farm, beside the volcanic rock escarpment, where basalt blocks fall down the cliff and spread randomly over the slope. Furthermore, surface water drains through joints in the lava cliffs and runs into the unstable material overlying the bedrock. The whole slope in this area is therefore considered a potential landslide area, where local and shallow landslides may take place in the colluvial cover on the bedrock [Ref 13]. However, any local landslides in this area are not expected to affect the new tank farm area.

A further potential landslide hazard was also identified during the landslide hazard study in the south-west area of the new tank farm. A fractured zone with a horizontal width of approximately 10 m along the cliff zone was identified at the volcanic rock escarpment. The fissures near the escarpment did not show signs of active deep-seated mass movement. Slope stability analysis in this area concluded that no deep-seated landslide hazards are expected at the south/west corner of the new tank farm [Ref 13].

At Ceylan Hill, the gradient of slopes is less than 15º near the proposed tank farm area and groundwater is not present. Based on site surveys during the landslide study and analysis of aerial photographs, there are no records of landslides taking place in the tephra unit in Ceylan Hill and the slopes here are not susceptible to such events [Ref 13]. The study therefore concluded that landslide hazards at this location can therefore be excluded.

10.5.3.5 Liquefaction

Liquefaction was observed during the Adana/Ceyhan earthquake in 1998 along the riverbanks of the Ceyhan River, approximately 15-20km from the proposed BTC Marine Terminal. Borehole data, soil investigations and seismic studies undertaken during subsequent geohazard studies at the proposed BTC Marine Terminal site conclude that liquefaction areas are not expected to occur at the new tank farm location due to the following [Ref 9]:

- the groundwater is below 30m; and
- the absence of relevant granular deposits as the bedrock is vesicular basalt below 1.5m to 10m of sandy gravely/clayey gravel soil and is underlain by basaltic breccia.

The potential for liquefaction (including lateral spreading) near the shoreline was also identified as minor during geotechnical studies [Ref 14]. Geohazard study conclusions regarding the potential for liquefaction along the alignment of the new jetty are discussed in Section 11.

10.5.3.6 Tsunamis

Tsunamis can be triggered by earthquakes, volcanic eruptions under the sea or landslides that displace water. However, there are no records of landslides and underwater volcanic eruptions in the Gulf of Iskenderun near the existing BOTAŞ Marine Terminal area [Ref 9]. Furthermore, the National Environment Research Council has recorded only a few tsunamis in the Eastern Mediterranean. A return period of 500 years yields an expected tsunami height of approximately 10m in the Eastern Mediterranean, for which no feasible counter design measures are possible. The usual lower limit for the onset of significant damage is a tsunami height of 4m. However, the risk of damage during the lifetime of the new jetty, (which is assumed to be 25 years), due to the occurrence of a tsunami is minor [Ref 9].

10.5.3.7 Other geohazards

Collapsing and expansive soil

Soil surveys conducted at the proposed BTC Marine Terminal site investigated the potential for soil collapse on the site. The terminal site is situated on vesicular basalt, basalt, sand and siltstone and claystone. Isolated gas pores in this material may exist, however, the extension of these pores is relatively small. In addition, soil types observed on the marine terminal site were determined as not susceptible to collapse. Therefore the risk of collapsing soil and subsequent damage to the tank farm and other structures is negligible [Ref 9].

Expansive soils can give rise to differential movement beneath structural foundations due to swelling and shrinking. Based on desk studies, the ability of flysch to swell or shrink is expected to be low. Additional soil investigations conclude that although there may be a potential for swelling in the area, it is anticipated to be low and the risk of this hazard is expected to be negligible.

Aggressive ground and groundwater

The potential for corrosion to the new tanks was assessed during site investigations. Soil resistivity measurements indicated that cathodic protection of the metallic components would be required up to 6 m depth [Ref 1 and Ref 9]. The risk of damage due to such a hazard is low.

10.6 SURFACE WATER AND GROUNDWATER

10.6.1 Surface water

There are few surface water features in the vicinity of the existing BOTAŞ Marine Terminal. Banyali Creek is the most prominent surface water feature, draining water to the west and north of Kara Hill (see Figure10.11). This creek has a number of ephemeral tributaries. The proposed tank farm facilities are located at the head of one such tributary, flowing south-west from the tank farm (see Figure10.11).

In addition, a small stream is present in a valley to the east of the tank farm. This surface water feature is supplied by water draining from Ceylan Hill to the west, and Hobur Hill to the east. The stream enters the sea at the settlement of Incirli, to the east of the existing BOTAŞ Marine Terminal.

Another ephemeral stream is located to the north-east of the proposed jetty, draining directly to the sea approximately 1km from the proposed jetty footing.

Gole pond is located 250m east of the existing tank farm at a height of 50m above sea level and lies within the existing BOTAŞ facility. The pond is approximately 5,000m^2.

10.6.2 Groundwater

There are considerable groundwater resources on the Cukurova plain, which lies to the north west of the proposed BTC Marine Terminal approximately 2km away (see Figure 10.11). There are two aquifer zones in the southern part of the plain (see Section 5.7.3) – an unconfined aquifer with a thickness of 100m and below this a confined aquifer with a depth of 150m. Groundwater quality in the unconfined layer is poor due to seawater intrusion, however, in the confined aquifer, the quality is high enough for use as drinking water. In the unconfined aquifer, groundwater is close to the surface and provides a source of irrigation for the intensive

agriculture in the area [Ref 2]. There is a smaller unconfined aquifer slightly closer to the proposed BTC Marine Terminal site.

Geotechnical studies carried out in the tank farm and general facilities areas of the proposed marine terminal indicate that the basalt and flysch[1] geological formation is generally poor in terms of groundwater in the immediate vicinity of the BTC Marine Terminal [Ref 4 and Ref 5]. Groundwater was found to exist near the sandstone layers in the flysch unit, although consideration should also be given to its existence along the boundary between the colluvium and the rock, particularly during wet seasons [Ref 4 and Ref 5]. However, these studies conclude that there are no substantial groundwater resources within the proposed BTC Marine Terminal area.

[1] Flysch: a sedimentary sequence consisting of marine deposits of dark, thinly bedded, fine-grained marls, sandstones, shales, clays, and muds.

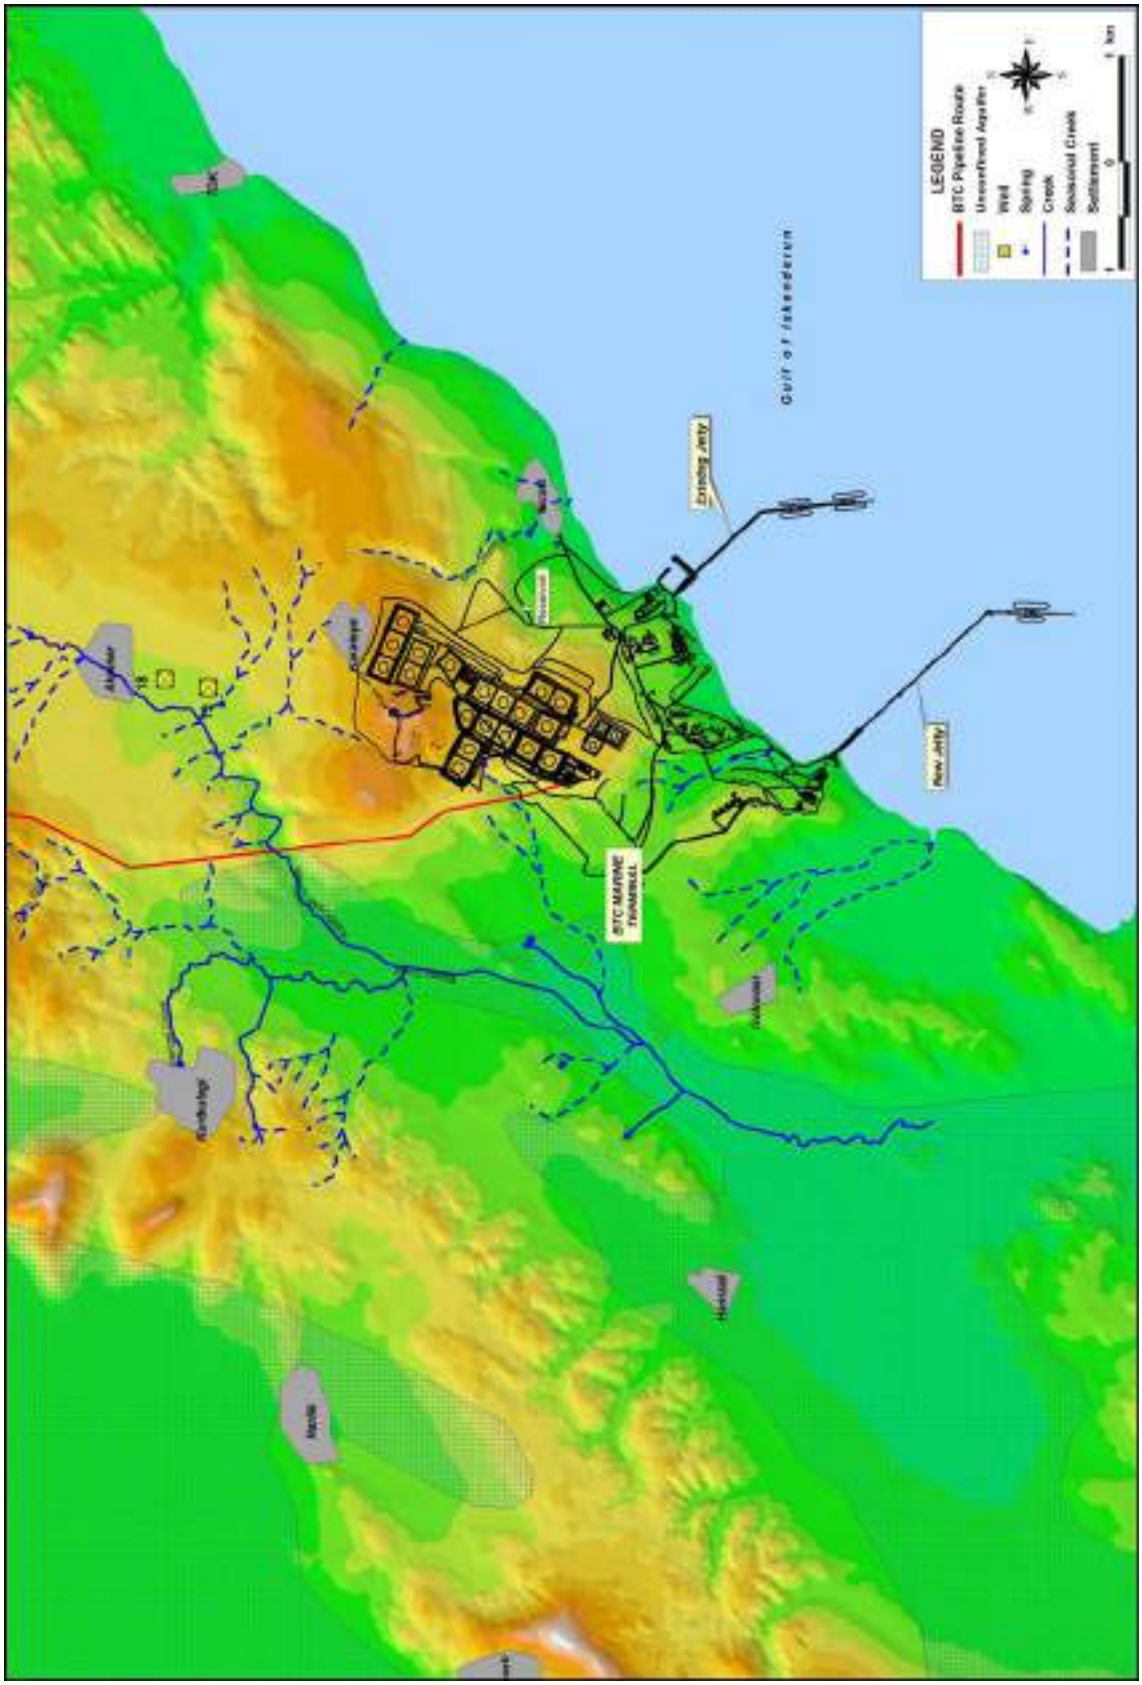

Figure 10.11 Surface Water and Groundwater Resources within the Vicinity of the BTC Marine Terminal

10.6.3 Irrigation

Irrigation systems are generally constructed by the State or by farmer co-operatives, but inevitably depend on the availability of water resources and topography (see Section 5.15.3). Contrary to the trend for Adana province, irrigation facilities are not widespread in the survey area and are only accessible to just over a quarter (27%) of the surveyed households, notably in the non-neighbouring settlements where commercial agriculture is more widespread.

Within the neighbouring settlements, Golovasi has the highest percentage of settlement land under irrigation (36%), followed by Incirli (33%). No land in Karatepe is under irrigation. See Plate 10.4 for an example of aerial irrigation in the study area.

Plate 10.4 Concrete Aerial Irrigation in Adana

10.6.4 Flood risk

The BTC Marine Terminal is situated on high ground (up to 125m above sea level), therefore, there is a low level of flood risk. Furthermore, the tephra and slag formation on Ceylan Hill and Kara Hill, which together form the drainage basin of the tank area, reduce the risk of surficial flooding in the tank area [Ref 8].

10.7 BIOLOGICAL ENVIRONMENT

10.7.1 Overview

The proposed BTC Marine Terminal site encompasses a variety of habitats, primarily maquis (scrub), semi-natural and managed wooded areas, agricultural areas and gardens associated with the site landscaping for the existing facilities (see Figure 10.12).

- Maquis scrub dominates the vegetation on the high ground at the tank farm location to the north of the facilities.
- The majority of land occupying the west of the facilities is used principally for agricultural purposes.

- Woodlands are located on the south facing slopes of the site, from approximately 100m above sea level stretching down to sea level, in places.
- The land occupying the southern area of the existing BOTAŞ marine terminal is mostly used for gardens, which form part of the landscaped terrain around the existing terminal facilities.

Habitat and faunal surveys and a Bird Survey have been undertaken at the proposed BTC Marine Terminal site [Ref 15; Ref 16]. These have identified key habitats and the presence of protected or important species, particularly within the site boundaries. Prior to the commencement of construction activities, detailed botanical surveys will be carried out at specific locations, such as along the terrestrial route of the loading lines, by an ecologist, (see Environmental Management and Monitoring Plan (EMMP), Appendix C1). This will serve as a guide during implementation of a Reinstatement Plan (RP, Appendix C2). In addition, faunal surveys will be undertaken prior to construction, to determine the presence and location of species within the proposed BTC Marine Terminal site and of nesting areas of resident bird species. These pre-clearance surveys will allow the development of site-specific measures to mitigate environmental impacts.

10.7.2 Protected areas

There are no internationally or nationally protected areas within the immediate vicinity of the BTC Marine Terminal. The nearest protected areas are as follows.

- Karatepe Aslantas National Park is approximately 60km north-east from the proposed BTC Marine Terminal. This is sufficiently far from the BTC Marine Terminal site as not to be at risk from impacts, including those that might arise from accidental events. It also has no ecological link to the site in terms of its habitat and species.

- Yumurtalik Lagoons Nature Reserve,, which is a 1st Degree Natural Site, is located approximately 25km south of the proposed BTC Marine Terminal. Yumurtalik Lagoons Nature Reserve is a huge complex of brackish and saline lagoons, salt and freshwater marshes, tidal mudflats, reedbeds, sand dunes and pine forests, which are important for a number of bird species. The reserve contains one of the few remaining Aleppo Pine (*Pinus halepensis*) forest communities, which are restricted in Turkey to West and South Anatolia (see Plate 10.5). This protected area was one of the sites included during the Bird Survey (see Section 10.7.3). A detailed description of Yumurtalik Lagoons Nature Reserve and its importance for bird species is given in Sections 11.4.8. The reserve would only potentially be at risk in the event of a large oil spill.

Plate 10.5 Aleppo Pine Forest at Yumurtalik Lagoons Nature Reserve

10.7.3 Protected species

10.7.3.1 Birds

A number of internationally and nationally threatened species were observed at or near the proposed BTC Marine Terminal site during the Bird Survey conducted between April and June 2001 [Ref 15]. In addition, a number of species were observed during a site walkover of the proposed tank farm and general facilities locations in October/November 2001.

The majority of birds recorded during these surveys were observed moving freely between the existing BOTAŞ Marine Terminal site and the surrounding farmland and are not known to breed in the area. These birds are therefore presumably passage migrants. The presence and locations of any nesting areas of resident species using habitats identified within the proposed BTC Marine Terminal site will be identified during habitat mapping and further ecological survey prior to the commencement of construction. Seasonal sensitivities for both breeding birds and passage migrants identified during the site walkover are discussed in Section 10.7.6.

Bird species recorded during both surveys are given in Table 10.8 and Table 10.9.

Table 10.8 Birds Recorded at the Proposed BTC Marine Terminal Site during the Bird Survey (April to June 2001)

Protection Status	Species
International Designation	
Annex I of EU Wild Birds Directive; Appendix II of CITES[1], CMS[2]; Annex A of EC Regulation 338/97[3]	Levant sparrowhawk (*Accipter brevipes*)
Annex I of EU Wild Birds Directive	honey buzzard (*Pernis apivorus*)
Annex I of EU Wild Birds Directive	booted eagle (*Hieraaetus pennatus*)
Annex I of EU Wild Birds Directive; Appendix II of CMS	glossy ibis (*Plegadis falcinellus*)

Appendix II CITES; Annex A of EC Regulation 338/97	barn owl (*Tyto alba*)

Nationally Protected	
Species listed in Central Game Committee Decision regarding species for which hunting is forbidden nationally	crested lark (*Galerida cristata*) shore lark (*Eremophilia alpestris*) yellow-vented bulbul (*Pycnonotus xanthopygos*)

1 CITES: Convention on International Trade in Endangered Species of Wild Flora and Fauna
2 CMS: Convention on Migratory Species
3 Council Regulation (EC) on the protection of species of wild fauna and flora by regulating trade therein (338/97)

The Yumurtalik Lagoons Nature Reserve is also recognised as an Important Bird Area (IBA) (see Section 11). Of particular note is the local population of globally threatened white-headed duck (*Oxyura leucocephala*), which is categorised as Endangered under the IUCN 2000 Red List [Ref 15]. This species is given protection by the National Parks and Game-Wildlife Protection General Directorate (NPGWP) in Turkey through the 'Game/Hunting Commission Decision', which issues a decision annually prohibiting the hunting of the white-headed duck. Birds surveyed at Yumurtalik Lagoons IBA are further discussed in detail in Section 11.

10.7.3.2 Reptiles and Amphibians

A number of protected reptile and amphibian species were observed during ecological surveys at the BTC Marine Terminal site (Yusuf Gemici, *pers. comm.*).

- Asia minor spur-thighed tortoise (*Testudo greca ibera*) – listed as Vulnerable under the IUCN 2000 Red List;
- yellow tree frog (*Hyla savignyi*) – internationally protected under Appendix II of the Bern Convention;
- green toad (*Bufo viridis*) – internationally protected under Appendix II of the Bern Convention;
- snake-eyed lizard (*Ophisops elegans*) - internationally protected under Appendix III of the Bern Convention;
- Danford's lizard (*Lacerta danfordi*) - internationally protected under Appendix III of the Bern Convention;
- banded skink (*Mabuya vittata*) - internationally protected under Appendix III of the Bern Convention;
- European blind snake (*Typhlops vermicularis*) - internationally protected under Appendix III of the Bern Convention;
- Caspian snake (*Coluber caspius*) - internationally protected under Appendix III of the Bern Convention;
- dwarf snake (*Eirenis modestus*) - internationally protected under Appendix III of the Bern Convention.

10.7.4 Habitats and vegetation

10.7.4.1 Maquis (scrub)

Various types of scrubland occur throughout the Mediterranean region, each being differentiated by a particular plant assemblage and the type of soil on which it grows. Key component species of the Anatolian maquis, but which have no international or national protection, include:

- kermes oak (*Quercus coccifera*);
- myrtle (*Myrtus communis*);
- chaste tree (*Vitex agnus-castus*);
- mastic tree (*Pistacia lentiscus*);
- turpentine tree (*P. terebinthus*);
- thorny broom (*Calycotome villosa*);
- Syrian privet (*Fontenesia phyllarioides*);
- thorny burnet (*Sarcopoterium spinosum*);
- sage-leaved rock-rose (*Cistus salviifolius*);
- Etruscan honeysuckle (*Lonicera etrusca*);
- fruiting jasmine (*Jasminium fruticans*);
- prickly rush (*Ruscus aculeatus*);
- narrow-leaved asparagus (*Asparagus acutifolius*).

Habitat assessment of the proposed BTC Marine Terminal site shows that maquis scrub dominates much of the area (see Figure 10.12), and has an average height of 2m. During the evaluation carried out at these sites, which are in the possession of BOTAŞ, located in the

proposed Marine Terminal, eightendemic maquis species, listed in the Turkish Red Data Book, were observed on the proposed Marine Terminal site during this assessment. These are *Centaurea solstitialis sp. Carneola*, *Phlomis longifolia var. bailanica*, *Stachys pumulia*, *Glycyrrhiza flavescens*, *Verbascum linearilobum*, *Bupleurum zoharii*, *Crocus cancellatus sp. cancellatus* and *Allium gayi*. Although these species have not been assigned categories by the IUCN, they potentially meet the IUCN 2000 Red List criteria and could be assigned categories at a later date (Yusuf Gemici, *pers. comm.*).

Most species on the existing BOTAŞ Marine Terminal site are annuals. Germination begins at the beginning of March and continues until mid June.

Sparser scrub, with significant bare areas on limestone soil is termed garigue. Although this is found in the wider area, garigue habitats have not been identified at the proposed BTC Marine Terminal site.

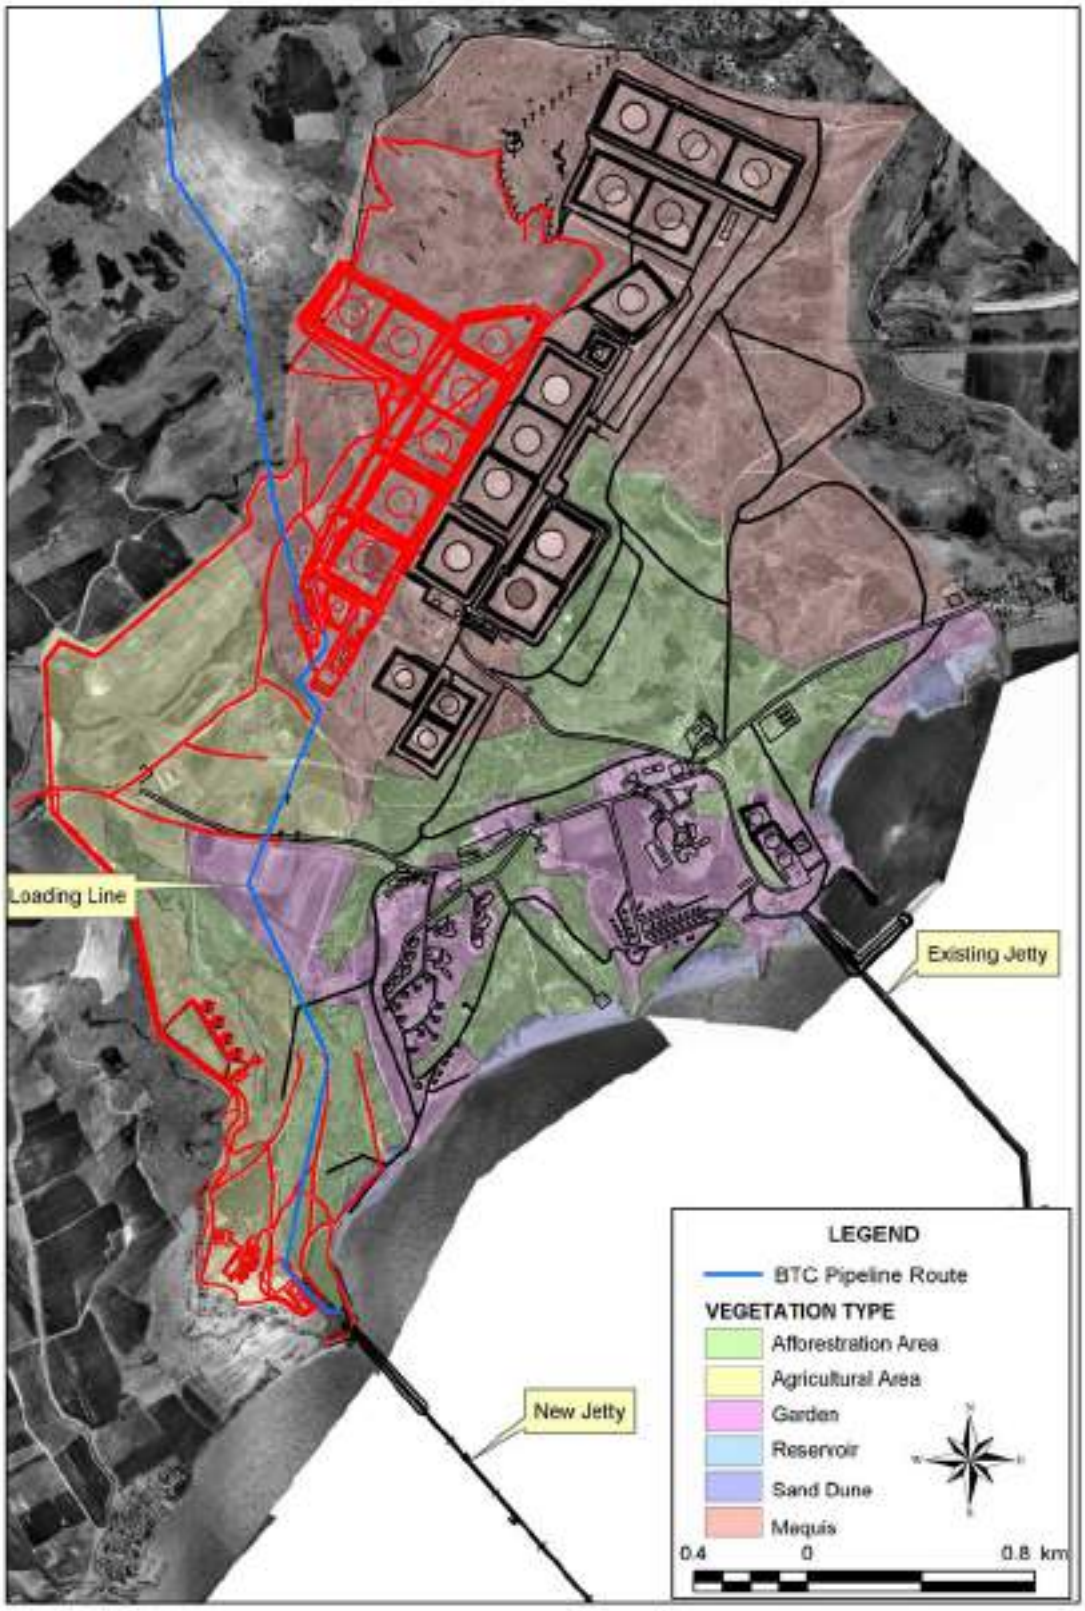

Figure 10.12 Vegetation Types in the BTC Marine Terminal Area

10.7.4.2 Woodland and orchards

The area around the proposed terminal facilities encompasses some significant plots of semi-natural woodland. Key species include the red pine (*Pinus brutia*), the umbrella pine (*Pinus pinea*) and the Mediterranean cypress (*Cypressus sempervirens*). These species, along with various other exotic tree and plant species, such as the eucalyptus *Eucalyptus canadulensis* and the acacia *Acacia cyanophylla*, were selected for afforestation of the existing BOTAŞ Marine Terminal site. Natural regeneration of this area was observed during surveys and afforestation was predicted to have taken place approximately 15 years ago [Ref 16].

Red pine occurs only in a managed plantation within the boundary of the existing BOTAŞ facility (see Plate 10.6). This species is ideally suited to the Mediterranean climate as it is not sensitive to soil or rock.

Plate 10.6 Red Pine (*Pinus brutia*) Afforestation at the Existing BOTAŞ Marine Terminal

The umbrella pine and Mediterranean cypress are relict species and have been planted along the borders of the red pine plantations [Ref 16]. Although they are not regarded as important for diverse flora, they do provide shelter and act as a habitat for some faunal species that cannot survive on the Cukurova Plain to the north, where intensive agriculture is undertaken [Ref 16].

Extensive orchards, predominantly citrus fruits and pomegranate (*Punica granatum*), have been planted on the grounds of the existing BOTAŞ facility.

10.7.4.3 Farmland

Agriculture is practised both on the site of the existing BOTAŞ facility and in the wider area to the north. Where terrain allows, intensive practices are used. The majority of agricultural land is of a relatively low quality within the boundaries of the existing BOTAŞ Marine Terminal site

(ie soil capability classes III, IV and VI) (see Section 10.3.2). Low quality agricultural soil capability classes IV and VII largely coincide with areas of afforestation.

10.7.4.4 Sand dunes

Sand dunes are found on the coastal fringe of the existing BOTAŞ Marine Terminal site, in a small sheltered bay between the existing jetty and the location of the proposed jetty.

The vegetation here is characteristic of the sheltered sandy coasts of West and South-west Anatolia. The dominant species are herbaceous, such as coastal morning glory (*Ipomoea stolonifera*), narrow-leaved bugloss (*Echium angustifolium*) and sea spurge (*Euphorbia paralias*), which grow to between 5–40cm high, and cover up to 25 % of the sand (see Plate 10.7). Their growth adds to the stability of the dunes [Ref 16].

Plate 10.7 Sand Dune Vegetation Dominated by Coastal Morning Glory (*Ipomoea stolonifera*) on the Beach at the Existing BOTAŞ Marine Terminal

There is also a sparse shrub community present (3% coverage), which grows to approximately 40cm high, comprising camelthorn (*Alhagi pseudoalhagi*) and Syrian mesquite (*Prosopis farcta*), neither of which are typical sand dune species. Over a small alluvial fan at the southern part of the beach where an ephemeral stream enters the sea, and the soil is composed of clay and sand, a dense semi-marshland community has formed dominated by Japanese blood grass (*Imperata cylindrica*), common reed (*Phragmites australis*), and tamarisk (*Tamarix smyrnensis*), growing to a height of up to 2m [Ref 16].

Although this type of sand dune vegetation is composed of common species, it is scarce locally, and greatly threatened along the coasts of west and south Anatolia because of the ubiquity of tourism development. The presence of sea daffodil (*Pancratium maritimum*) here is noteworthy since the species is a nationally rare plant and is listed in the Red Data Book for Turkey; see Plate 10.8. It prefers stable dune systems and is adversely affected by tourism, as it is frequently picked when found [Ref 16].

Plate 10.8 Specimen of the Sea Daffodil (*Pancratium maritimum*) – Growing at the BTC Marine Terminal Site

Sand dunes are also present beyond and to the south of the proposed BTC Marine Terminal site. They have an approximately 30 % coverage of shrubs, growing to a height of between 1.5 and 2 m. Dominant species include Oleander (*Nerium oleander*) and Chaste tree (*Vitex agnus-castus*), which were once widespread and dense throughout this area, but are now greatly reduced as a result of cutting by tourists [Ref 16]. Tamarisk (*Tamarix smyrnensis*) may also be found on alluvial sediments.

The field layer varies in height from between 20 and 40 cm, with the rush (*Juncus subulatus*) being dominant. However, Japanese blood grass (*Imperata cylindrica*) was found to grow to a maximum height of 1m. Sand dune communities in this area were observed to be species-poor due to the difficult growing conditions experienced [Ref 16], but provide important nesting habitat for Loggerhead and Green turtles (see Section 11.4.5).

10.7.5 Fauna

A detailed faunal survey will be conducted under the supervision of a qualified ecologist, (see the EMMP in Appendix C1), prior to the commencement of construction activities to identify the presence and location of threatened or potentially sensitive species at the proposed BTC Marine Terminal site.

The diversity of habitats within the existing BOTAŞ facility (and the proposed terminal) supports a commensurate diversity of fauna. The presence of large numbers of raptors on the proposed BTC Marine Terminal site indicates an abundance of rodents and other small mammals. The Brown Hare (*Lepus capensis*) has also been observed at the BTC Marine Terminal [Ref 16].

Bats were frequently observed at dusk throughout the site. The presence of significant stands of trees provides suitable habitat for several species. The managed woodlands on the terminal site also provide a habitat for species not found elsewhere in the wider area. For example, the goitred gazelle (*Gazella subgutturosa*), which is extinct in the wild in Turkey, has been re-introduced at the existing BOTAŞ facility, where a managed herd is corralled [Ref 16].

Several species of snakes and lizards known to be present in the area are presumed to frequent the site where a suitable habitat is present.

A number of protected amphibian species were observed during ecological surveys at the BTC Marine Terminal site (see Section 10.7.3.2). In addition, the European pond turtle (*Emys orbicularis*), which is listed as Lower risk-near threatened (LR-nt) under the IUCN 2000 Red List, was observed in irrigation canals within the immediate vicinity of the existing terminal site.

10.7.6 Seasonal sensitivities

Breeding birds are likely to be present between March and September, with the peak breeding season concentrated between April and July. Migratory birds generally pass through the area in the spring between mid March and late May and again during the summer/autumn between late July and mid October. Non-breeding summer visitors occur in the area between mid March and late August.

Passage migrants are also a potential seasonal sensitivity. These birds tend to congregate at staging posts, which may include wetland areas such as the Yumurtalik Lagoon, and will be susceptible to disturbance as a result of their low energy budgets. However, the presence of such staging posts is unlikely within the proposed BTC Marine Terminal site. Seasonal sensitivities for birds at Yumurtalik lagoons are discussed in Section 11.

Table 10.10 summarises the seasonal sensitivities for birds observed at the BTC Marine Terminal.

Table 10.10 Seasonal Sensitivities

	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP	OCT	NOV	DEC

peak period other important period

No information is available for other habitats and/or species at the BTC Marine Terminal site other than those in Attachment 1 of the EMMP (see Appendix C1), which sets out seasonal sensitivities for species along the BTC Pipeline Route.

10.8 AIR QUALITY

10.8.1 Sources of information

An air quality sampling programme was developed taking into consideration the following factors:

- type of pollutants that will be emitted by the project activities;
- significance of the pollutant emissions in terms of quantity;
- existing air pollution sources near the project locations;
- seasonal atmospheric variations;
- proximity of population centres, and environmentally sensitive areas (ESAs) to the project emission sources.

In general, air emissions related to the proposed construction of the BTC Marine Terminal are minor in quantity and amenable to control through the adoption of standard mitigation techniques. However, Particulate Material (PM) emissions may be significant during the construction of the terminal. Therefore, PM measurements have been undertaken to determine the background levels.

Operation of the marine terminal may result in ground level concentrations of pollutants in the vicinity of the tank farm and the tanker loading area. Air quality has been monitored in the vicinity of the proposed BTC Marine Terminal and existing monitoring data for a nearby site has been referred to in the determination of background air quality.

The seasonality of the ambient pollutant levels has been taken into consideration. Typically, background air pollutant levels in the Adana Province are lower during the wet season (between January and May) [Ref 25] and higher in the dry season (between June and September) [Ref 17]. This is particularly true for the atmospheric PM levels, which are mostly generated by wind erosion. Measurements for PM and Volatile Organic Compounds (VOCs) have therefore been taken during the dry season in order to observe the worst-case ambient concentrations.

Ambient VOC levels were sampled in terms of total VOC concentration, which is a parameter commonly used for detecting the presence of organic pollutants that may potentially be emitted from oil export facilities.

The air quality measurement program entailed monitoring over a one-week period in the dry season between 21-28 September 2001 and in the wet season between 7 - 17 February 2002 to examine existing PM_{10}[1] and VOC levels at the proposed BTC Marine Terminal site. Figure 10.13 shows the locations of both PM_{10} and VOC sampling sites.

[1] **PM_{10}**: the fraction of suspended particulate matter (SPM) with an aerodynamic diameter of less than 10 micrometers (**μm**).

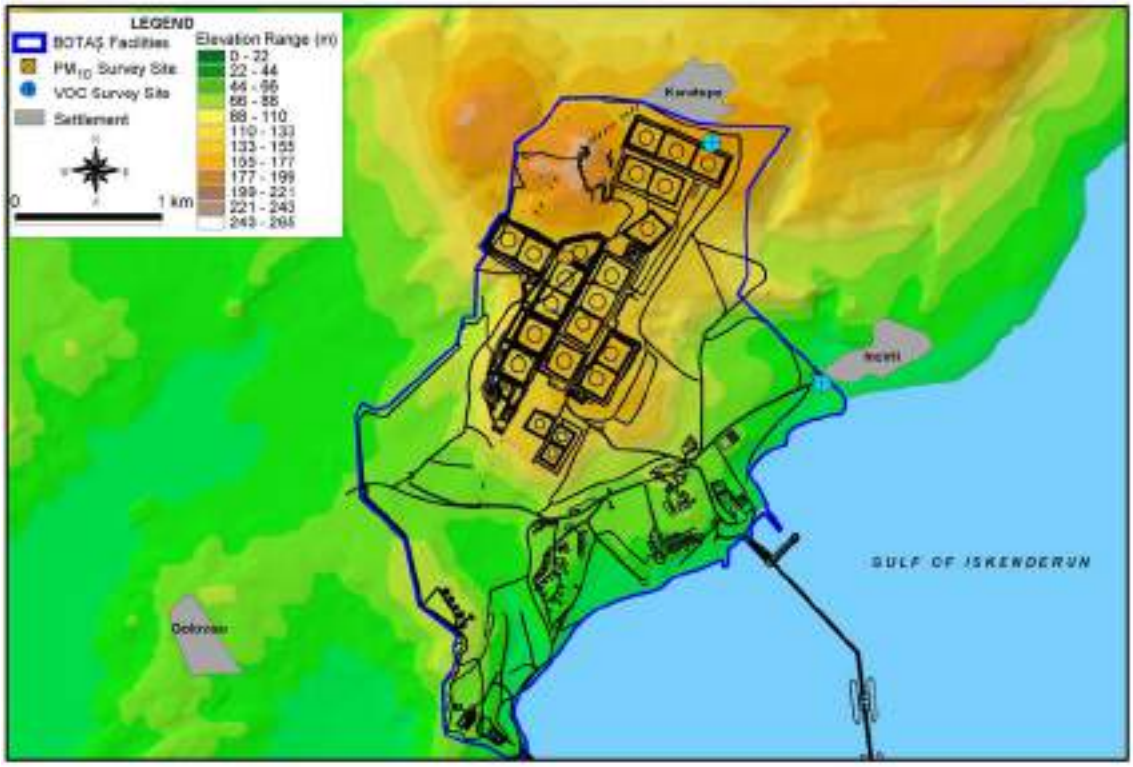

Figure 10.13 Location of Air Quality Sampling Sites in the BTC Marine Terminal Area

10.8.2 PM_{10}

PM_{10} concentrations were measured at the proposed BTC Marine Terminal site using a Minivol portable low-volume sampler equipped with a 10-µm inlet [Ref 17]. Seven daily average concentrations were measured. The results of the PM_{10} survey are given below in Table 10.11.

Table 10.11 PM_{10} Concentrations at the Existing BOTAŞ Marine Terminal Location

DATE	PM_{10} CONCENTRATION (µg m^{-3})
Dry Season	
22/9/2001	28.8
23/9/2001	23.1
24/9/2001	48.0
25/9/2001	57.4
26/9/2001	54.8
27/9/2001	49.1

13/2/2002	37.1
Weekly Average	30.0

Source : [Ref 17]

Comparison of these concentrations with short-term limit values under the Turkish Regulation on Preservation of Air Quality (300µg m^{-3}) indicates that these values are well below this limit. Whereas, comparison with short-term limit values under European Community (EC) standards, (50µg m^{-3}), indicates that there are two instances where the short-term limit value is exceeded. The EC limit value allows a maximum of 35 exceedances of 50µg m^{-3} per year. However, it is reasonable to use the Turkish standard as the air quality benchmark since elevated atmospheric particle levels could be explained on climatic grounds.

10.8.3 VOCs

The VOC survey was conducted using a portable Perkin-Elmer Photovac Voyager Gas Chromatograph - Photoionization Detector (GC/PID) with a detection limit of 0.5 parts per million (ppm)[1]. Both continuous and source screening measurements were taken during the survey.

The existing BOTAŞ tank farm and marine loading facilities are the main sources of the ambient VOC. During the source screening survey, the highest VOC concentrations were observed in the ballast tank area of the existing BOTAŞ Marine Terminal (6.7ppm, or 10 g m^{-3} near the control room) as the ballast tanks are uncovered and receive oily ballast from incoming ships [Ref 17]. VOC concentrations at the existing tank farm were not as high, as the crude oil tanks are covered and sealed [Ref 17]. Ambient VOC measurements were surveyed through continuous measurements conducted at two locations in the immediate vicinity of the existing BOTAŞ facilities. These locations are the Incirli settlement entrance to the east of the existing BOTAŞ facilities and Karatepe settlement to the north-east. These sites were chosen because of their downwind locations from the existing facilities. Briefly, the survey involved taking a sample for 10 seconds every 5 minutes over a 24 hour period at each of the two locations, giving a total of 576 measurements.

During this survey, total VOC concentrations were all below the detection limit, with the exception of six instantaneous (ie 10s) measurements, given in Table 10.12. These measurements were probably due to changes in source strengths [Ref 17]. The highest instantaneous VOC concentration was observed at Karatepe settlement. Long-term VOC concentrations are likely to be significantly lower than these instantaneous concentrations.

Table 10.12 VOC Concentrations at the BTC Marine Terminal Location

LOCATION	DATE	TIME	CONCENTRATION (ppm)	CONCENTRATION mg m^{-3}
Karatepe	25/09/2001	16:02	6.7	10.1
Karatepe	25/09/2001	16:32	6.4	9.6
Karatepe	25/09/2001	17:01	8.5	12.8
Karatepe	25/09/2001	17:16	1.7	3.1
Karatepe	25/09/2001	17:31	7.2	10.8
Incirli	28/09/2001	02:19	3.1	4.7

Source: [Ref 17]

Under the Turkish Regulation for the Preservation of Air Quality, the VOC standard has been taken as the total hydrocarbon standard, an hourly maximum of 280µg m^{-3} (see also Appendix D), ie 0.28mg m^{-3}. It is difficult to make a comparison between the standard and the measured values. Only six out of 576 values were above the instrument detection limit and these were all

[1] Conversion factors from ppm VOC to mg m^{-3} are not straightforward. They vary from 1ppm = 1.8mg m^{-3} to 1ppm = 4mg m^{-3} for propane and heptane respectively. Taking a mean of 1ppm = 2.9mg m^{-3} the detection limit was in the order of 1.5mg m^{-3}.

very short-term episodes. However, the instrument detection limit of 1.5mg m^{-3} is also above the standard so there is no certainty that the values measured as below detection were not above the standard.

VOCs are not easy to address in terms of monitoring. Measured concentrations are easily influenced by transient sources such as road traffic and farm vehicles. VOCs are also difficult to address in terms of composition since they may comprise variable mixtures of alkanes and aromatic hydrocarbons etc. The alkanes may make up the bulk of the VOC but it is the aromatics that have the potential greatest human health implications. For these reasons a long-term monitoring programme has been set up to establish more information on VOCs in the project area. This will primarily involve a passive monitoring approach where BTEX (benzene, toluene, ethyly benzene and xylene) diffuser tubes are deployed and regularly analysed.

10.8.4 Existing air quality in the wider terminal area

Baseline information on the existing SO_2, NO_2, PM_{10}, and NO concentrations in the wider terminal area is available from two previous studies undertaken for the Sugozu Power Plant, which is under construction approximately 4-5km from the proposed BTC Marine Terminal. Information from this study is intended to supplement site-specific data already gathered and is considered indicative of the general conditions within the wider BTC Project area.

Long-term concentrations of SO_2, PM_{10}, NO, and NO_2 pollutants are presented in Table 10.13 [Ref 18]. The data were collected during two different seasons (spring and summer; ie wet and dry seasons).

During the wet season total PM (TPM) measured, whereas in the dry season, only PM_{10} was measured due to a difference in the use of sampling instruments for each season. Complementing these measurements, a long-term (annual) passive sampling monitoring study was also conducted [Ref 19]. In this study, annual average concentrations for SO_2 and NO_2 were 7 and 11µg m^{-3}, respectively.

Table 10.13 Average Pollutant Concentrations in the Wider Terminal Area

POLLUTANT PARAMETERS	GROUND LEVEL CONCENTRATION (µg m^{-3})	
	10 DAYS (Wet Season)	38 days (dry season)
SO_2	3.06 ± 0.89	4.84 ± 3.80
TPM	53.29 ± 18.75	7.76 ± 17.55*
NO	1.43 ± 0.30	0.32 ± 0.74
NO_2	6.44 ± 2.37	7.47 ± 4.20
NO_x	7.87 ± 2.52	7.80 ± 4.58

*Only particles with less than 10µm aerodynamic diameter (ie PM_{10}) were measured.
Source: [Ref 19]

The concentrations in Table 10.13 were measured over 10 days and 38 days for the wet and dry seasons, respectively. These values are not directly comparable with the standard short-term limit values, which are measured over a 10-minute to 24-hour period. Comparison with long-term limit values identified in the Turkish Regulation on Air Quality, EC standards and World Health Organisation standards has therefore been made.

Annual mean long-term limit values under the Turkish Regulation are 100µg m^{-3} for NO_2, 200µg m^{-3} for NO and 150µg m^{-3} for both SO_2 and PM; under EC standards, 40µg m^{-3} for NO_2 and 40µg m^{-3} for PM; and under the World Health Organisation standards, 50µg m^{-3} for SO_2.

The measured concentrations of all pollutants are below the limit values and therefore it is likely that the long-term limits will be met. The data indicate little in the way of combustion related

pollution in the area. This is with the exception of PM, for which the long-term limit value under the EC standard was exceeded during the wet season. However, this survey data should be treated with a degree of caution, as it may not be representative of the rest of the year and may have a natural rather than combustion source. However in 2003, approximately 18 months before the BTC Marine Terminal commences operation, the coal-fired power plant at Sugozu will become operational. This will constitute a substantial new source of combustion related pollution in the area and for this reason further long-term air quality monitoring of sulphur and nitrogen oxides and PM_{10} will be undertaken for the project area.

10.9 NOISE

Daily continuous (24 hours) measurements were conducted at two residential locations in the area – Karatepe settlement and the BOTAŞ lodges [Ref 20]. Karatepe settlement is near the existing tank farm of the BOTAŞ facilities whereas the BOTAŞ lodges are inside the existing BOTAŞ Marine Terminal area (see Figure 10.14).

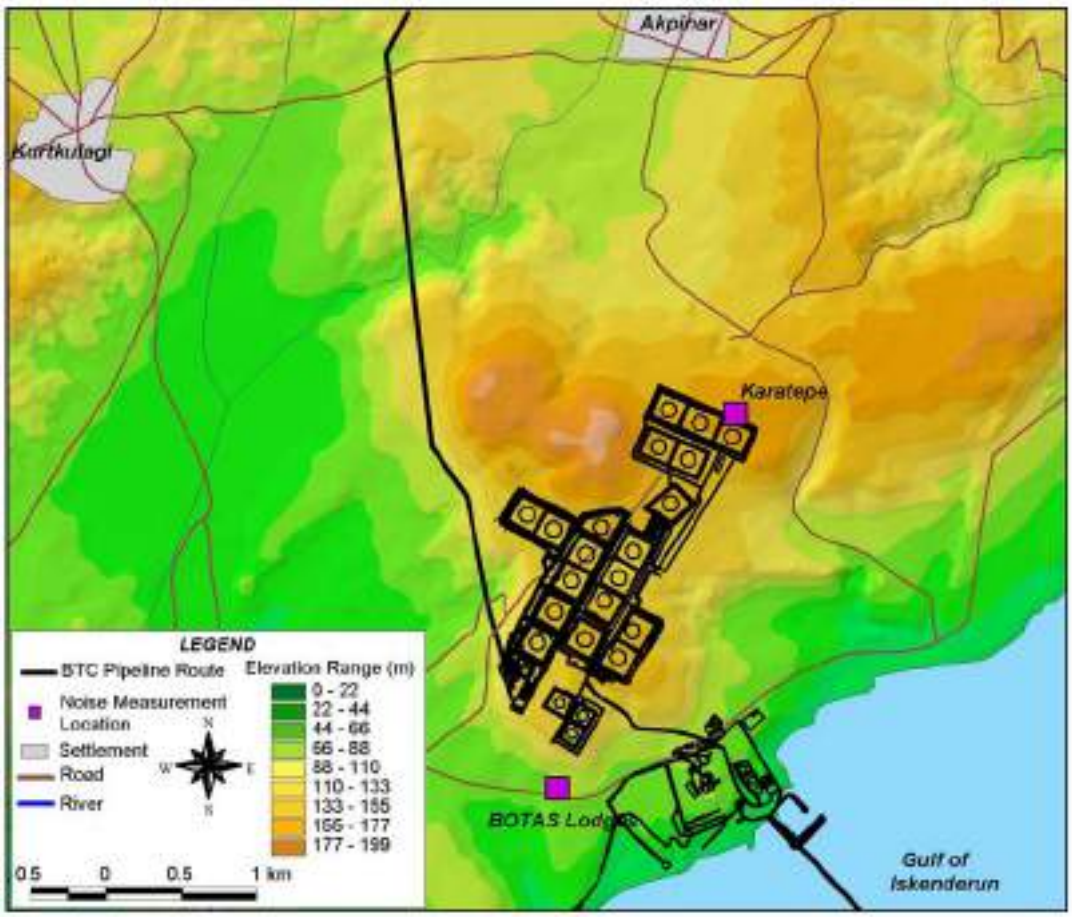

Figure 10.14 Location of Noise Measurements in the Vicinity of the BTC Marine Terminal

At Karatepe, day and night time L_{eq} values as well as daily average L_{eq} were calculated using the 24-hour continuous noise measurement records. These L_{eq} values are presented in Table 10.14 and Table 10.15 for weekend and weekday levels, respectively.

Table 10.14 Day and Night L_{eq} Values and Daily Averages of L_{eq} Measurements at Karatepe (weekend)

	DAY; 06:00-22:00 NIGHT; 22:00-06:00[1]	DAY; 07:00-22:00 NIGHT; 22:00-07:00[2]
L_{eq} (day)	43.3	43.2
L_{eq} (night)	36.4	37.3
L_{eq} (daily-24 hr)	41.0	

Table 10.15 Day and Night Time L_{eq} Values and Daily Averages of L_{eq} Measurements at Karatepe (weekday)

	DAY; 06:00-22:00 NIGHT; 22:00-06:00	DAY; 07:00-22:00 NIGHT; 22:00-07:00
L_{eq} (day)	52.3	52.2
L_{eq} (night)	58.9	58.4
L_{eq} (daily-24 hr)	54.5	

Noise sources in the area comprise road traffic and daily activities of the residents as well as activities both at the existing BOTAŞ tank farm and jetty.

As shown in Table 10.14 and Figure 10.15 daily average noise levels at the weekend are lower than during the week. This is because the measurement location is close to the existing BOTAŞ Marine Terminal, where daily routine activities during the week are the main sources of noise in the area. Increased night time noise levels during the working week at Karatepe were likely to be caused by repair and maintenance work that was reportedly carried out during the cooler hours of the night between 15:00 and 08:00 hours [Ref 20]. Peaks were seen between 21:00 and 22:00 hours in diurnal records as a result of such works in the existing tank farm. These levels exceed the 45 dBA World Health Organisation criterion above which sleep disturbance may occur.

At the BOTAŞ Lodges, day and night time L_{eq} values as well as daily average L_{eq} were also calculated using the 24-hour continuous noise measurement records. These L_{eq} values are presented in Table 10.16 and Table 10.17 for weekend and weekday levels respectively.

Table 10.16 Day and Night L_{eq} Values and Daily Averages of L_{eq} Measurements at BOTAŞ Lodges (weekend)

	DAY; 06:00-22:00 NIGHT; 22:00-06:00	DAY; 07:00-22:00 NIGHT; 22:00-07:00
Leq (day)	50.6	50.6
Leq (night)	46.3	46.7
Leq (daily-24 hr)	49.2	

Table 10.17 Day and Night Time L_{eq} Values and Daily Averages of L_{eq} Measurements at BOTAŞ Lodges (week day)

	DAY; 06:00-22:00 NIGHT; 22:00-06:00	DAY; 07:00-22:00 NIGHT; 22:00-07:00
L_{eq} (day)	46.1	45.8
L_{eq} (night)	45.4	45.6
L_{eq} (daily-24 hr)	45.9	

[1] The Turkish Noise Control Regulation defines 'day' as 06:00 – 22:00 and 'night' as 22:00 – 06:00. This statement applies to Tables 10.11 – 10.14.

[2] The World Bank Noise Standard defines 'day' as 07:00 – 22:00 and 'night' as 22:00 – 07:00. This statement applies to Tables 10.11 – 10.14.

Comparison of Table 10.16 and Table 10.17 indicates that weekend L_{eq} values are higher than those recorded during the week, probably because BOTAŞ personnel spend most of their weekday time away from the lodges (ie administrative buildings, tank farm, workshop and jetty) [Ref 19]. Weekday noise levels are therefore lower in the vicinity of lodges.

Similarly, survey results at Karatepe show diurnal changes in noise levels at BOTAŞ lodges, with peaks between 21:00 and 22:00, due to loading/unloading at the jetty and maintenance works conducted in the existing tank farm.

10.10 CULTURAL HERITAGE

Desk studies and preliminary consultations with the Ministry of Culture and the Adana Provincial Directorate on the Protection of Cultural and Natural Entities were undertaken during the Basic Engineering phase and Scoping stage of the EIA. These identified two archaeological sites 1.5 km north-west of the proposed BTC Marine Terminal site. These sites are Boyali Mound and Mercimek Mound and were deemed vulnerable sites only in terms of the potential impacts associated with oil spills [Ref 2]. There were no archaeological sites identified within the BTC Marine Terminal [Ref 2].

Furthermore, baseline studies conducted during the Detailed Engineering stage also confirm the absence of archaeological sites in the area of the BTC Marine Terminal [Ref 22].

10.11 DEMOGRAPHICS

It is important to document existing population levels, migration patterns and gender/age balances as a benchmark for future change. This is particularly salient in view of evidence that in-migration associated with existing developments has already taken place and is shaping the gender and age balances of settlements in the existing BOTAŞ Marine Terminal area. Understanding the demographic characteristics of an area also allows for the prediction and assessment of the types of impacts likely to be experienced as a result of the proposed development (eg the existing ratio between numbers of residents and available services will provide an indication of the ability of the survey area to absorb additional population totals).

10.11.1 Provincial level demographic overview

According to the latest official census[1], the total population of Adana province in 1997 was just below 1.7 million. Annual population growth between 1990-1997 was approximately 1.2%, slightly lower than that for Turkey as a whole (1.5%). This increase was associated with in-migration from neighbouring provinces, particularly South-Eastern Anatolia, a direct result of increasing industrialisation and new development in Adana[2]. These include: 1) the South-eastern Anatolian Development Project; 2) the Adana-Yumurtalik Free Trade Zone (FTZ); 3) the existing BOTAŞ developments; and 4) Siemens Powerhouse (also known as Sugozu Thermal Power Plant) and Sanko Holdings Petro-Chemical Development to the south of the BOTAŞ property, both of which are currently under construction (see Plate 10.9). These developments in conjunction with the proposed BTC Marine Terminal development and jetties will continue to act as a growth magnet for the province and could potentially cause a change in livelihoods, through land take, decreased access to marine resources and greater opportunities (see Box 10.2, Box 10.3 and Box 10.4).

[1] State Institute of Statistics (Census 1997). Complete data for the 2000 Census is currently under review and has not yet been publicly released.
[2] In 1990, 70% of the Adana population lived in urban areas compared with 76% in 1997.

Box 10.2 South-Eastern Anatolian Project (GAP)

The South-Eastern Anatolian Project (Guneydogu Anadolu Projesi or GAP) is a multi-sectoral and integrated regional development project based on the concept of sustainable development. The project aims to eliminate regional development disparities by raising people's income level and living standards. The project also aims to contribute to such national development targets as social stability and economic growth by enhancing the productive and employment generating capacity of the rural sector. The project area covers nine provinces in the Euphrates-Tigris basins and Upper Mesopotamia plains (Adiyaman, Batman, Diyarbakir, Gaziantep, Kilis, Mardin, Siirt, Sanliurfa and Sirnak). The area between Iskenderun and Yumurtalik is regarded as the main gateway for the Project.

The regional development programme spans a range of sectors including irrigation, hydraulic energy production, agriculture, urban and rural infrastructure, forestry, education and health. Its water resources programme will involve the construction of 22 dams and 19 power plants and irrigation schemes in an area extending over 1.7 million hectares. The total cost of the Project is 32 billion USD.

Source: [Ref 24]

Box 10.3 The Adana-Yumurtalik Free Trade Zone (FTZ)

The Adana-Yumurtalik Free Trade Zone (FTZ) is located east of the existing BOTAŞ property near the settlements of Sarimirza and Ceyhan, close to the Toros Gubre Fertilizer facility. It was designated in 1985 to:

- increase export-oriented investment and production in Turkey;
- accelerate the transfer of foreign capital and technology to Turkey;
- provide inputs to the economy in an economical and orderly manner through the presence industrial;
- promote commercial and service activities; and
- increase the utilization of foreign trade opportunities and foreign financial instruments.

Source: [**Ref 26**]

The Adana-Yumurtalik FTZ is not yet operational and initial infrastructure is currently being established on site. It aims to increase the industrialization of the region by providing a tax free zone governed by international regulations for trade and other commercial activities. It is possible the Adana-Yumurtalik FTZ will one day be connected to the existing Mersin FTZ.

Source: Meeting with Yumurtalik Municipality Representative, Adana

Box 10.4 Existing and Proposed Marine Jetties in the Region

There are four existing active jetties in the region: 1) BOTAŞ Ceyhan operated by BOTAŞ, 2) BOTAŞ Dortyol operated by BOTAŞ; and 3) two Toros Gubre Fertiliser Facility jetties operated by Tekfen Holdings. Three additional jetties are proposed along the 15 km stretch of coastline including:

- the BTC Jetty which will be operated by BOTAŞ and is described in more detail in Section 9;
- the Siemens Powerhouse (also referred to as the Sugozu Thermal Power Plant) jetty which is under construction, although no vessel is expected to berth; and
- the Sanko Holdings jetty, (close to Sugozu), which will be used for transporting chemical materials. Construction has started, but was recently halted because of environmental concerns.

Plate 10.9 Sugozu Thermal Power Plant, Adana

10.11.2 Settlement level overview

Box 10.5 provides an overview of the demographic baseline for settlements potentially impacted both directly and indirectly by the BTC Marine Terminal. The findings are explored in more detail in the subsequent section culminating in Table 10.18, which provides a demographic summary by settlement.

Box 10.5 Overview of Demographic Baseline

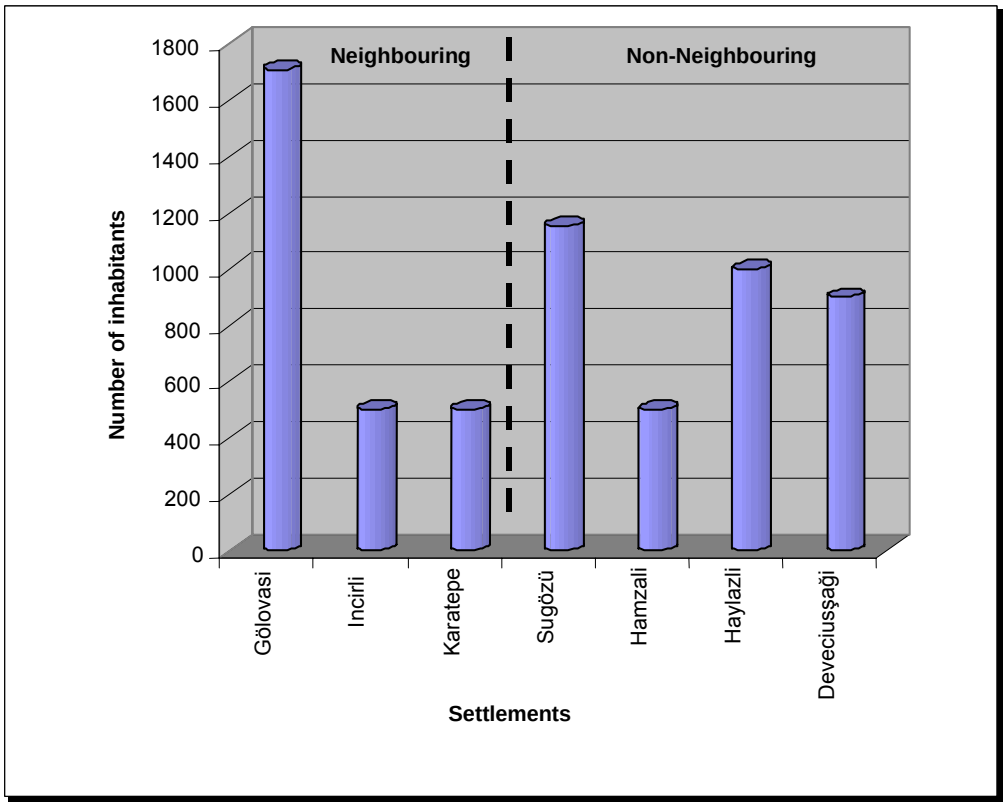
- **Provincial:** industrialisation is attracting a significant number of migrants to the province of Adana correlating with increasing population levels for the province as a whole. This trend is generally limited to urban areas of the province.
- **Population levels:** Golovasi (on the western boundary of the BOTAŞ site) is the largest settlement in the project area followed by Sugozu (a settlement close to Sugozu Thermal Power Plant, approximately 4-5km south-west of the BOTAŞ site). Only three of the Muhtars (of Golovasi, Incirli and Karatepe) reported a natural increase in population (ie birth rates exceeding death rates) in their settlements over the past five years.
- **In-migration:** according to the Muhtars, none of the surveyed settlements have experienced in-migration in *the past five years*, with the exception of Sahil Sitesi, which attracts people wanting to buy second homes in the settlement.
- **Out-migration:** this has been experienced in three non-neighbouring settlements (Sugozu, Hamzali and Haylazli) and is indicative of a lack of employment opportunities. No neighbouring settlements have experienced out-migration. Consultation findings indicate that the lack of out-migration among neighbouring settlements is due, in part, to expectations of employment from the proposed BTC Marine Terminal development.
- **Gender:** a gender imbalance is evident in the area (53% male) with a noticeably higher ratio of men in Incirli (60% men: 40% women), Haylazli (60% men: 40% women) and Sugozu (57% men: 43% women). This was not attributed by the Muhtar to in-migration over the past five years and could either be a result of earlier in-migration for existing developments (eg BOTAŞ Marine Terminal) or due to high female mortality.
- **Seasonal Workers:** 10% of the economically active population in Golovasi are seasonal workers migrating temporarily for construction or agricultural work. Very small percentages live in Deveciusagi and Karatepe.

- **Age Distribution:** Incirli exhibits the highest dependency ratio (1.6 dependents to every one working adult) and Golovasi the lowest (0.5 dependents per working adult). These dependency ratios are below the national average and associated with the demographic process of out migration, fertility (ie low birth rates) and mortality (ie high death rates).

- **Language and Religious Distribution:** the vast majority of the surveyed residents are Turkish speaking Sunni Muslims.

10.11.3 Population levels and household size

Population levels for each settlement are given in Figure 10.15. All three of the neighbouring settlements (Golovasi, Incirli and Karatepe) have experienced a natural increase in population attributed, by their respective Muhtar, to a rise in birth rates. No explanation was offered for this increase in fertility. With the exception of Sahil Sitesi, average household size for the surveyed settlements mirrors the Adana average (approximately five inhabitants). Both are lower than the average household size for Turkey, which is six[1], a trend indicative of more urbanised, nuclear households. The smaller average household size exhibited by Sahil Sitesi (three inhabitants) can be explained by the use of the settlement for retirement or secondary homes.



Source: Settlement Survey 2001
NB: Sahil Sitesi is a hamlet of Golovasi and is, where relevant, included with the Golovasi data. Karayilan has no Muhtar, hence there is no data from the settlement survey.

Figure 10.15: Population Levels in the Surveyed Settlements in the Marine Terminal Area

[1] Source: SIS, 1996.

10.11.4 Migration patterns and gender distribution

- **In-migration:** Sahil Sitesi is the only settlement in the project area where the Muhtar identified in-migration over the *past five years* - a trend associated with the construction of secondary homes by individuals from the Ceyhan district. However, the increased number of males in the survey area, particularly in Incirli and Haylazli where 60% of the population are males, suggests that male in-migration may have taken place prior to the past five years, as a result of the development of BOTAŞ Marine Terminal (see Figure 10.16).

- **Out-migration:** the non-neighbouring settlements, according to their respective Muhtars, have experienced out-migration in the past five years, due to a perceived lack of employment opportunities within the settlements. Residents from Sugozu tend to migrate to either Ceyhan to work in trade or to work in the construction of the nearby Sugozu Thermal Power Plant. For the latter, residents tend to stay in dormitories near the power plant to save on transport costs. Educated residents from Hamzali continue to migrate to Adana for work in the tertiary sector (eg as office workers). In comparison, there is no out-migration from neighbouring settlements. Residents in Karatepe explained this through their aspirations for permanent employment from the proposed marine terminal development and the strong solidarity and social networks amongst residents.

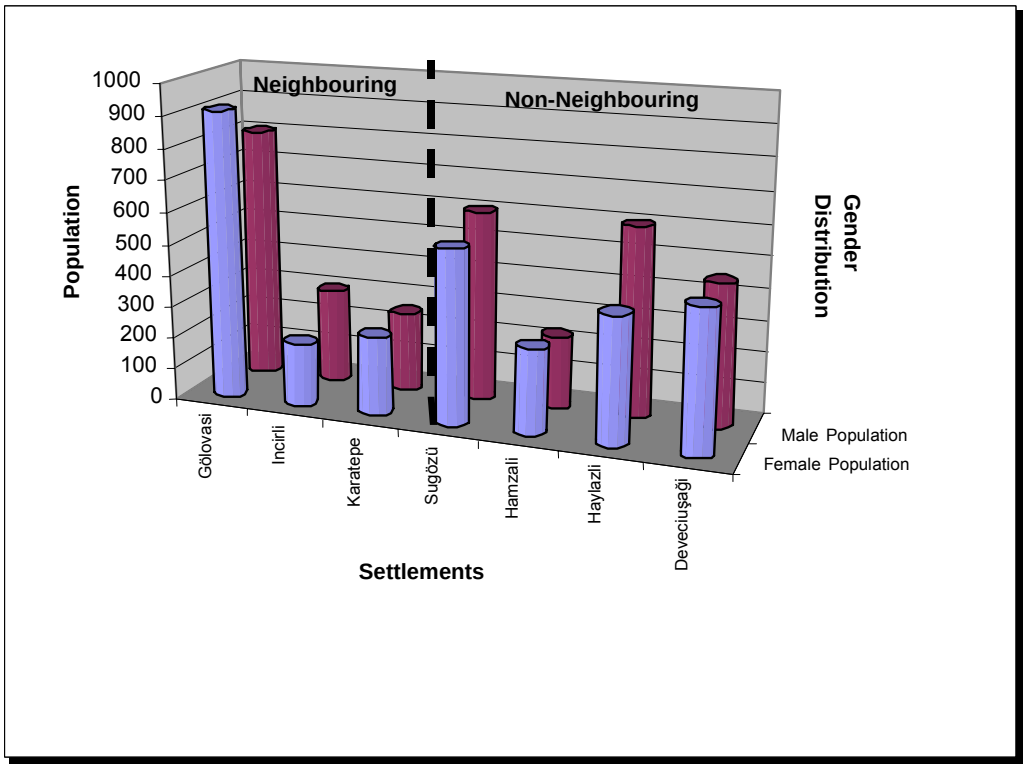
Box 10.6 Social Networks in Neighbouring Settlements

One experienced heavy machine operator stated: *'I am earning 150 million TL per month, but if I do the same work in Istanbul, I will earn the same money. At least here I do not pay rent and my family looks after me. When I was unemployed, my uncle looked after my family. Once, when my son got sick he covered all the medical expenses. Why then should I go to Istanbul?*

Source: Machine Operator, Marine Terminal Consultation

- **Seasonal Migration:** seasonal workers leave their settlements to work during peak harvest/ construction seasons. According to the Muhtars in the project area, seasonal workers only live in: 1) Golovasi, where they comprise 10% of the economically active population[1]; 2) Deveciusagi, where they comprise 2%; and 3) Karatepe, where they comprise 1%. Seasonal workers are hired periodically within the borders of Adana, between May and the end of November (see Plate 10.10). Not all seasonal workers are agricultural labourers. Some work as drivers for heavy construction machinery, notably in the summer months when construction is at its peak.

[1] For the purposes of the survey, 'economically active' individuals are between 19 and 59 years of age. Legally, however, economically active individuals are considered to be between the ages of 15 and 65.



Source: Settlement Survey 2001
N.B. Karayilan has no Muhtar, hence there is no data from the settlement survey

Figure 10.16: Gender Distribution for Surveyed Settlements in the Marine Terminal Area

Plate 10.10: Seasonal Cotton Worker's Camps along the Main Road between Ceyhan and Yumurtalik

10.11.5 Age distribution

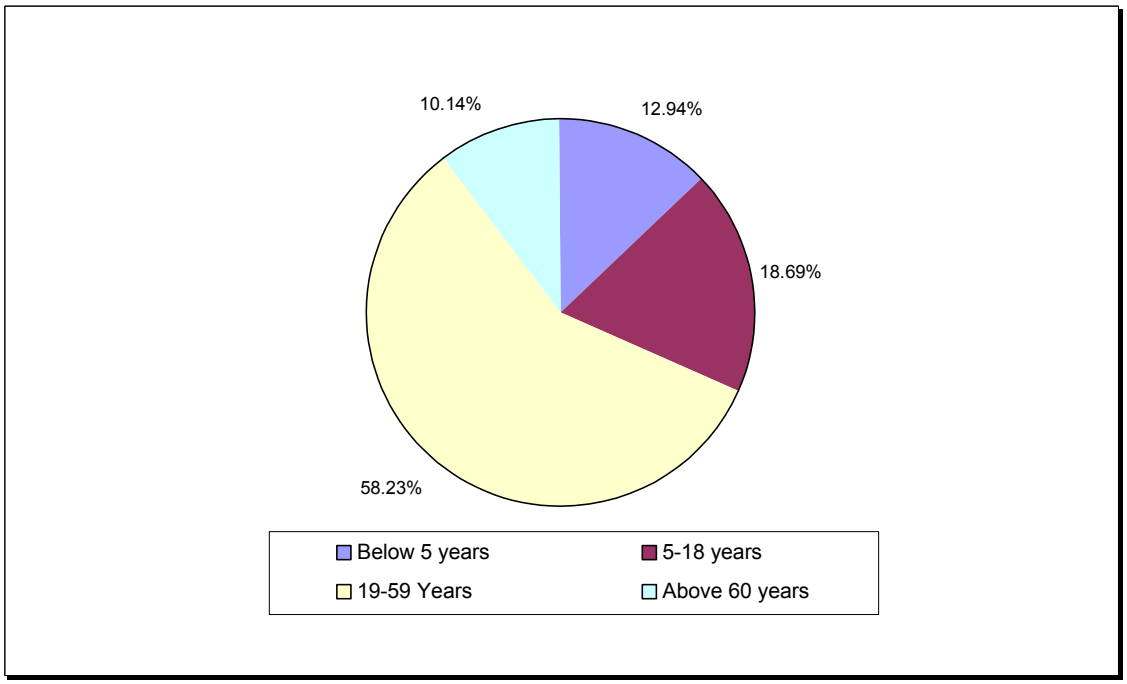
The findings highlight the following (see Figure 10.17):

- **Low fertility rates:** according to the Muhtars, settlements exhibit surprisingly low birth rates, a trend usually corresponding with increasing education levels (particularly of females) and access to family planning. For example, Golovasi has the lowest number of inhabitants under five years of age (8%, compared with the survey average of 13%). However, the Muhtars of the neighbouring settlements noted a rise in birth rates.

- **High mortality rates:** contrary to world-wide development trends, the low birth rates are not concomitant with an ageing population. Instead, the surveyed settlements exhibit a small elderly population, particularly in the neighbouring settlements. Golovasi[1] has the lowest number of elderly residents of both genders (5% compared with the 10% survey average), whereas Incirli and particularly Karatepe have very few elderly women (eg only 15 of the 55 individuals over 60 are female in Karatepe) contributing to the gender imbalance discussed earlier. One possible explanation for the small proportion of elderly people is that health services are insufficient to attend to the needs of the elderly as corroborated by the survey (see Section 10.14.4).

- **Low dependency ratios:** dependency ratios are the ratio of dependent individuals (children and retired adults) against individuals of working age (defined in this survey as between the ages of 19 and 59). They are important, because they are indicative of levels of development and the availability of adults for current and future employment. On average, 55% of the surveyed population is of working age. This ranges from 38% in Incirli to 66% in Golovasi, correlating with the highest (1.6) and lowest (0.5) number of dependents per working adult respectively. These very low dependency ratios emulate those found for Adana province and are typically associated with increased development and in-migration of working adults.

[1] Not including Sahil Sitesi where some of the secondary homes are used by retired inhabitants.



Source: Settlement Survey 2001

Figure 10.17: Age Distributions for Surveyed Settlements in the proposed BTC Marine Terminal Area

10.11.6 Language and religious distribution

Adana province is multicultural[1]. There are Arabic speaking groups of both Sunni and Alevi origin[2], a limited number of non-Muslim groups and a few immigrants of Kurdish origin or from the Balkans. However, the vast majority of inhabitants are Turkish speaking Sunni Muslims.

The main language spoken day to day in all surveyed settlements in the marine terminal survey area is Turkish and the residents are predominantly Sunni Muslim. However, four households in Golovasi, two in Sugozu, two in Hamzali and one in Haylazli speak west European languages and three households (one each in Incirli, Hamzali, and Deveciusagi) speak Arabic[3] on a daily basis. Only two households surveyed have Kurdish speakers (one each in Sahil Sitesi and Deveciusagi)[4].

10.11.7 Demographic summary

Table 10.18 summarises the demographic findings for each surveyed settlement.

[1] Andrews, PA (1989). Ethnic Groups in the Republic of Turkey (Weisbaden: Reichart, 1989).
[2] The two main Islamic sects in Turkey.
[3] Arabic is primarily taught in secondary education institutions (notably religious vocation schools). Therefore the low concentration of Arabic speakers is more likely to correspond to the settlement Imams rather than ethnic Arabs.
[4] It is possible, that this is an underestimation, respondents will not always admit to speaking different languages.

Table 10.18 Demographic Summary

SETTLEMENT	AVERAGE HH* SIZE	TOTAL POPULATION	NATURAL INCREASE	IN-MIGRATION	OUT-MIGRATION	GENDER DISTRIBUTION (M/F) (%)		DEPENDENCY RATIO ****
Neighbouring Settlements								
Golovasi	5	1,710	Yes	No	No	47	53	0.5
Sahil Sitesi **	3	-	-	Yes	No	-	-	-
Incirli	5	500	Yes	No***	No	60	40	1.6
Karatepe	5	500	Yes	No	No	50	50	1.0
Non-neighbouring Settlements								
Sugozu	4	1,150	No	No***	Yes	57	43	0.6
Hamzali	5	500	No	No	Yes	46	54	1.1
Haylazli	5	1,000	No	No ***	Yes	60	40	0.8
Deveciusagi	6	900	No	No	No	50	50	0.6

* HH = Household
** Difficult to ascertain as most people (many of whom are retired) live in the settlement only during summer months.
*** Although the Muhtars reported that no in-migration had been experienced over the past five years, gender ratios in these settlements (more men than women) indicate that in-migration may have occurred prior to the past five years and/ or high female mortality.
**** Defined as the number of dependents (<19 years and >55) for each adult of working age.

10.12 LAND OWNERSHIP AND USE

10.12.1 Overview

The jetty development will result in the establishment of two security zones (an operational and exclusion zone), with a resultant decrease in access to marine resources within these designated areas. Similarly, increased industrialisation in the wider project area (of which the BTC Project is a part) will result in increased land take and the potential for in-migration to the area. Understanding the impact of this on the local population requires an analysis of the availability of land and land use in the area. An assessment of the impacts, outlined above, therefore requires the documentation of land ownership patterns, land use and availability of land prior to the development of the marine terminal. Box 10.7 provides an overview of land status within the neighbouring and non-neighbouring settlements.

Box 10.7 Overview of Land Ownership, Distribution and Use

- **Land Ownership:** the two most common land ownership patterns in the surveyed settlements are private and State ownership, although the former is more common in Golovasi, Hamzali and Haylazli. The prevalence of State land increases east of the existing BOTAŞ development towards the Adana-Yumurtalik Free Trade Zone, where land expropriation has taken place. Some of this land is rented, but in the case of land once owned by Karatepe, this lies unused.
- **Land Distribution:** in neighbouring settlements, land is concentrated in the hands of a minority (eg in Golovasi only 19% of all respondents own land with 80% of these owning more than one plot). Conversely, in the non-neighbouring settlements, more than 80% of surveyed households in Sugozu, Hamzali and Haylazli own land, with more than 50% owning more than one plot. These settlements are dependent on commercial agriculture as a main source of income.
- **Land Titles:** the non-neighbouring settlements, which are more reliant on commercial agriculture, have land titles for more than 90% of their land. Fewer households, between 50-80% have land titles in the neighbouring settlements. Consultation findings suggest that the vast majority of secondary homeowners in Sahil Sitesi lack land titles.
- **Irrigation:** of the neighbouring settlements, Golovasi has the highest percentage of land under irrigation (36%), followed by Incirli (33%). No land in Karatepe is under irrigation. Of the non-neighbouring settlements, Sugozu has 67% of its land under irrigation, in sharp contrast to Haylazli, with only 0.2% of land irrigated, explained by limited access to water resources in the latter.
- **Land Use - Crops:** grain is the most widespread crop and is primarily used for household consumption with the exception of the more market oriented settlements of Sugozu, Hamzali and Haylazli. Cotton is produced for the markets in all settlements and is grown, with the exception of Haylazli, on irrigated land. The non-neighbouring settlements exhibit greater crop diversification and grow nuts, grapes and watermelon.
- **Land Use - Livestock:** cattle and poultry are the most important livestock (particularly in Incirli and Karatepe) and are kept by 38% and 42% of surveyed households respectively. Sheep are only kept in Incirli and Karatepe. Animals are generally kept for household consumption.

10.12.2 Land ownership and distribution

Parts of Turkey have not undergone cadastral surveys, hence land ownership patterns are difficult to ascertain. A large proportion of land in Turkey is owned by the State and in Adana, State owned land is more common than communally owned land.

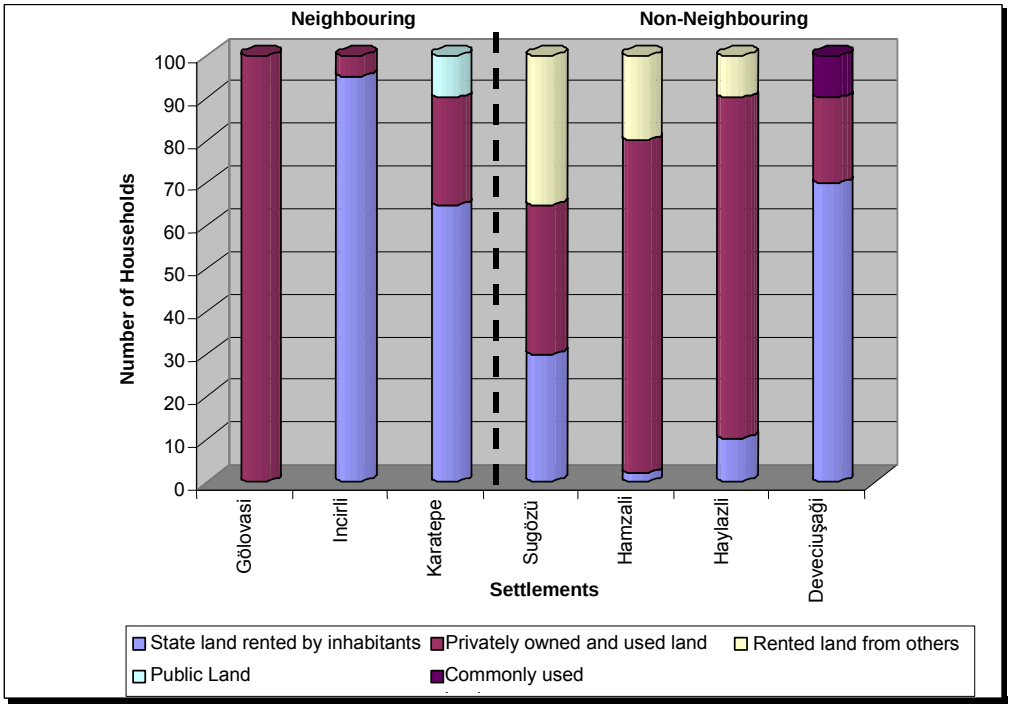
Figure 10.18 illustrates the main landowners in the surveyed settlements.

- **State owned:** in Incirli, Karatepe, Sugozu and Deveciusagi, the majority of land is State owned. Residents from the latter two settlements rent State land, whereas in Incirli and Karatepe a large proportion of once arable land was expropriated in the 1990s and designated a Free Trade Zone. Residents stated that the majority of this land remains unused.

- **Privately owned:** the bulkof land in Golovasi, Hamzali and Haylazli (100%, 78% and 80% respectively) is privately owned, in line with the high proportion of owner-occupied land found in settlements along the pipeline in Adana province.

- **Private rental:** the survey found a low proportion of rented land, controlled by an unstructured private rental market. Karatepe, Hamzali and Haylazli (all settlements where agriculture is the main source of income) do, however, rent land from a number of other neighbouring settlements.

- **Communal Land:** only 10% of land in both Karatepe and Deveciusagi is communal land. There is no communal land in the other surveyed settlements correlating with the low importance of commercial animal husbandry.



Source: Settlement Survey 2001
N.B. Karayilan has no Muhtar, hence there is no data from the settlement survey

Figure 10.18: Land Tenure in the Surveyed Settlements in the Marine Terminal Area

The main findings of the survey of land distribution are as follows:

- **Land Concentration:** the concentration of land into the hands of only a few landowners is most acute in the neighbouring settlements, particularly in Golovasi, where the minority are employed in agriculture and the majority in other sectors, most notably fishing and trade. Here, there are approximately four/five big landowners each within excess of 100ha[1]. Only 10-15 fishermen rent approximately 0.1ha of land each as a subsidiary form of income. In the non-neighbouring settlements, agriculture is more important as a source of income and most households own some land (see Figure 10.19).

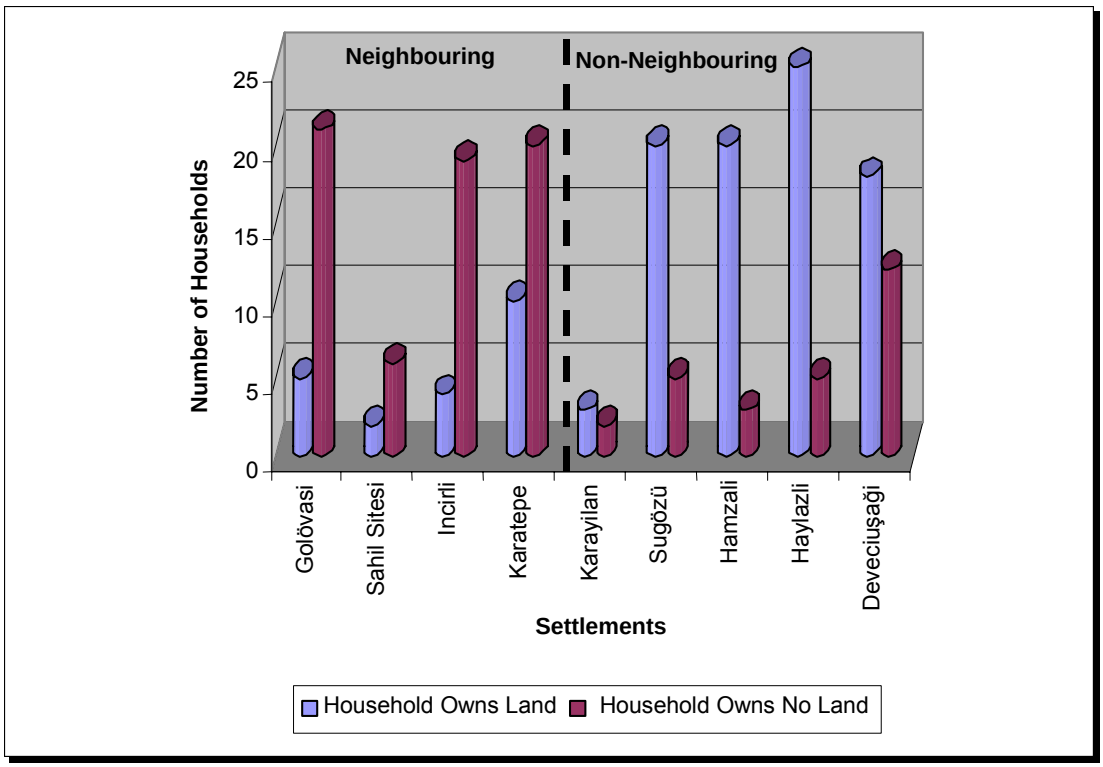
- **Household landholding:** between 1950-1980, the region was characterised by large landholdings. Subsequent division by inheritance has meant that small and medium-scale land ownership patterns are dominant[2]. Households in Haylazli and Hamzali have the largest landholdings in the survey area (243ha and 197ha respectively). This correlates with their greater dependency on agriculture and higher levels of commercialisation. Golovasi has the third largest land holding (137ha). This is most probably because it has been less affected by land expropriation in the past than settlements such as Karatepe and Incirli, and because the surrounding topography is potentially more suited to agriculture. However, the average is also elevated by a handful of big landowners.

[1] One hectare is equal to 10,000 m^2, and one decare is 1000 m^2.
[2] Source: Mayor of Yumurtalik Municipality, Adana Province

- **Average number of plots (fragmentation):** the number of agricultural plots per settlement ranges from 102 in Hamzali to 5 in Karayilan. In general, settlements dependent on agriculture as their main source of income have a larger number of agricultural plots per settlement and suffer greater land fragmentation indicative of inheritance patterns.

- **Average plot size:** the average plot size varies from 8ha in Golovasi to 0.9ha in Karatepe. The small figure for Karatepe is indicative of the large amount of land expropriated for industrial developments. The average plot size for the survey area is 2.4ha. This average (depending on land capabilities) is sufficient for commercialisation and capital-intensive farming.

- **Land titles***:* the percentage of land owned by respondents with land titles for their largest land plot within each settlement varies from 55% in Karatepe to 100% in Hamzali and Karayilan. In general, settlements more dependent on land (and earning sufficient income) have land titles for their main land plots. For many of the secondary home owners living along the coast near Sahil Sitesi, there are disputes over the legal status of the land and it is estimated that a high proportion do not have land titles.



Source: Household Survey 2001

Figure 10.19: Land Ownership by Settlement

Box 10.8 Secondary Home Owners in Sahil Sitesi

Secondary homeowners in Sahil Sitesi are tradesmen from Adana and Ceyhan or retired individual (See Plate 10.11). There are approximately 150 secondary homeowners, although exact figures are difficult to determine, notably because only a small proportion of homeowners were present during the survey. These homeowners bought land from an owner who occupied treasury lands for 19 years. This was just below the 20 years of occupancy required before obtaining rights of ownership. Thus residents are currently paying rent to the State, although some have taken the matter to court. The State has also defined the houses as illegal and has ordered their demolition, an order that is being argued in the courts. It should be noted that the State cannot destroy the houses if they are more valuable than the land itself, although because some of the houses are less than 100m from the shore they are of questionable legality. The uncertainty of the ownership of the secondary homes is a source of concern raised in the consultation meetings as well as in subsequent correspondence received from homeowners.

Source: Marine Terminal Consultation, Adana

Plate 10.11: Secondary Home Owner Properties in Sahil Sitesi, Adana

10.12.3 Land use: agricultural activities

10.12.3.1 Arable farming

The desktop research, supplemented by household surveys and discussions with community and government representatives have indicated the following pattern of arable farming.

- **Main crops:** grain crops such as wheat, barley and maize are the most widespread crops in the survey area, grown in all surveyed settlements, and by approximately 50% of surveyed households (see Figure 10.20).

- **Secondary crops:** cotton is the second major product, grown by approximately 40% of households surveyed generally correlating with the presence of irrigation facilities. Households in Golovasi also grow fruit trees and a range of other crops is grown in the non-neighbouring settlements including: watermelon (in Deveciusagi and Haylazli); nuts

and seeds (in Sugozu and Deveciusagi); wine grapes (in Hamzali); and timber (in Sugozu, Hamzali and Haylazli).

- **Crop diversity:** the settlements surveyed are generally characterised by low product diversification primarily due to reliance on rainfed agriculture, particularly in Haylazli and Golovasi. However, according to the Mayor of Yumurtalik Municipality, with irrigation the area would be suitable for green house products and tropical fruits.

- **Crop use:** *Grain* is grown mainly for household consumption in Incirli, Golovasi, Karatepe, Karayilan and Deveciusagi. However, 51% of grain produced in the survey area is produced for market – the majority of which is grown in the ore commercially orientated settlements of Sugozu, Hamzali and Haylazi. *Cotton* is produced primarily for markets outside the settlements. *Wine grapes* are produced for a mix of household consumption and markets. Fruit is produced exclusively for household consumption (see Plate 10.12 to Plate 10.16)

- **Cropping patterns:** one crop is grown per year by the majority of households in the neighbouring settlements although timber (from trees grown in Golovasi, Sugozu, Hamzali and Haylazli) is multi-cropped.

- **Costs of production:** crops sold in local markets are generally associated with greater investment. For example, average household input costs are highest for cotton (2,725 million TL; or 1,703 USD[1] per season per household); grain (2,195 million TL; or 1,372 USD per season, per household) and certain crops categorised as 'other' such as watermelon (2,245 million TL, or 1,403 USD per season, per household). Fruit trees (grown exclusively for household consumption) have the lowest average costs because their production is not labour intensive. Input costs are particularly high for cotton due to the high investment in irrigation and intensive seasonal labour requirements. Input costs are noticeably high for grain production in Sugozu, possibly due to investment in fertilisers and harvest machinery in this more commercialised settlement.

- **Crop yields:** grain productivity is highest in Golovasi (where average household yields are approximately 38,000kg from the last harvest in 2001, most of which was used for household consumption) and Hamzali (approximately 36,000kg, most of which was sold at markets outside the settlement). This is perhaps due to good growing conditions in Golovasi and high investment in Hamzali (eg fertiliser). High cotton yields were also reported in Golovasi (on average 20,000kg from the last harvest per household) and in Haylazli, high yields of 'other' crops – mainly watermelon (72,500kg from the last harvest in 2001).

- **Reduction in production:** approximately 80% of respondents stated that they had experienced a reduction in agricultural production over the past five years. A number of reasons were given for this overall trend including aridity (57% respondents), low agricultural prices (9%), rising input costs (9%) and the current economic crisis (8%). All respondents from Karayilan and Haylazli attributed this to aridity, correlating with the water supply problems experienced in both settlements.

[1] Currency conversions are based on January 2002 figures with a rate of 1million TL = USD 1.60

Plate 10.16 Vineyard in Adana

Box 10.9 Trends in Agriculture

Because of the division of land by inheritance, the same amount of land is now used to provide income for an increasing number of individuals. Recent agricultural policies have also adversely affected agricultural production and the lack of adequate irrigation facilities puts a barrier on product diversification into, for example, greenhouse products and tropical fruits. As part of an attempt at agricultural diversification, farmers have increased the area allocated to corn products as a second harvest in recent years. However, this initiative failed to produce benefits when, in 2001, there was a corn disease, thus discouraging farmers to diversify production. Opportunities still exist to diversify production if there is adequate investment for example in irrigation infrastructure or in manufacturing initiatives associated with agriculture.

Source: Mayor of Yumurtalik Municipality, Adana

- **Increase in production:** only 6% of all respondents stated that there had been an increase in production attributed to either good rainfall or an increase in irrigation.

In summary, the findings suggest that the non-neighbouring settlements (with the exception of Deveciusagi) are more market orientated, investing more heavily in arable agriculture and therefore reaping the benefits of higher yields. In the neighbouring settlements, arable agricultural production is more subsistence based and most households are more dependent on non-agricultural based income (eg fishing and wage income).

10.12.3.2 Livestock farming

Animal husbandry is a main source of income for 7% of surveyed households, more than half of which are from Incirli, and the remainder from Deveciusagi, Karatepe and Hamzali. More often than not, the majority of surveyed households keep livestock for their own consumption (see Figure 10.21).

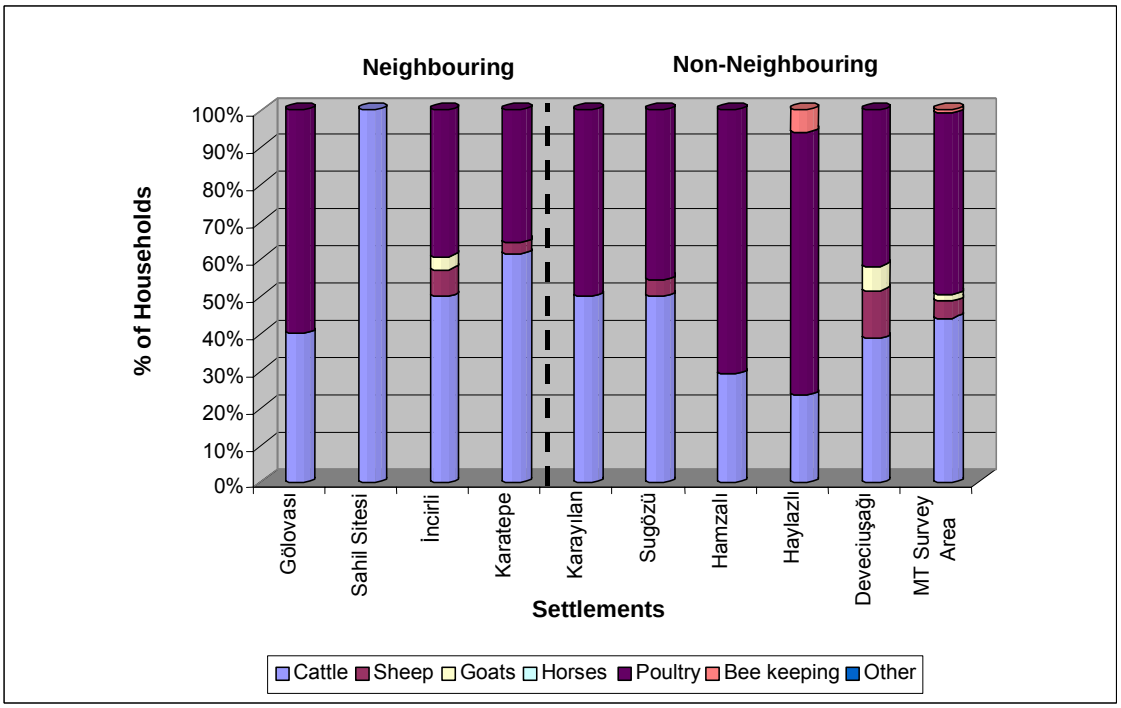
- **Poultry:** these are the most common type of livestock and are kept by 42% of households in the surveyed settlements, and in excess of 70% of households in Karayilan and Hamzali. Poultry are mainly kept for household consumption, although only a couple of households in Karatepe breed poultry to sell eggs and some meat in external markets.

- **Cattle:** these are the second most common type of livestock in the survey area and are kept by 38% of all households surveyed including 61%, 64% and 80% of households in

Incirli, Karatepe and Karayilan respectively. However, land expropriation by BOTAŞ in the 1970s has limited the availability of communal land for grazing and only Karatepe has communal land (10% of all land) where cattle can be grazed.

- **Herd size:** Incirli, Karatepe and Karayilan have the highest average herd sizes ranging from three to five cows, reflecting the average herd size for the province. This small herd size is indicative of the subsistence nature of cattle husbandry. Only a small number of cattle are sold to outside markets by households from Karatepe, Sugozu and Deveciusagi. The majority is produced for household consumption.

- **Sheep and goats:** these are relatively uncommon with only 4% and 2% of households breeding these animals respectively. Incirli and Karatepe have large average flocks of sheep (200[1] and 60 respectively). Sheep in the latter are produced solely for markets whereas the remainder of sheep and goats in the survey area are produced primarily for household consumption. Table 10.19 summaries land ownership and use for the surveyed settlements.



Source: Household Survey 2001

Figure 10.21 Percentage of Households in the Surveyed Settlements Owning Animals in the BTC Marine Terminal Area

[1] Two households in Incirli are engaged in sheep breeding. One of these households has 100 sheep and the other has 300 sheep.

(Source: Settlement and Household questionnaire (HH = Household) 2001) [Ref xx]

[1] Karayilan is a part of the municipality of Kurtpinari. It does not have its own Muhtar. As a result, no information was available from the settlement level survey on this topic.

10.13 LIVELIHOODS, EMPLOYMENT AND SKILLS

10.13.1 Overview

An understanding of livelihoods, employment and skills within the survey area fulfils the following key objectives: 1) it allows one to assess the extent to which people are dependent on various forms of livelihood and thus their ability to cope should access to these livelihoods be diminished; 2) it provides an indication of the availability of local residents for project employment; and 3) it provides an indication of the suitability of local residents for semi-skilled and skilled employment.

The findings are reported under the following headings.

- **Levels of income** describes levels of income/wealth (financial and capital assets) and changes to living conditions.
- **Sources of livelihood** describes the importance of cash and non-cash earnings (eg wage income, food production, fishing and social benefits).
- **Levels of employment** describes the levels of unemployment and availability for temporary employment (this is a proxy indicator for underemployment).
- **Sources of employment** identifies the main employment sectors in which respondents are actively engaged, including both subsistence and income-based activities (a more in-depth exploration of the fishing and tourism sector is provided).
- **Skills and experience** identifies the extent to which respondents have previous construction experience and/or skills appropriate for large-scale construction projects.

Box 10.10 provides an overview of levels and sources of livelihood and employment findings. This is followed by a more detailed review culminating in Table 10.20 summarising the findings by settlement surveyed.

Box 10.10 Overview of Livelihoods, Employment and Skills in the Survey Area

Levels of Livelihood: Sugozu is the highest-ranking settlement in terms of both income and assets whereas Karatepe (the settlement directly adjacent to the existing oil storage tanks) is the lowest. Golovasi and Incirli are ranked third and seventh respectively. Living conditions in the majority of the settlements (namely Incirli, Golovasi, Karatepe, Hamzali, Haylazli, Deveciusagi and Sahil Sitesi) appear to have deteriorated in the last five years, attributed to the rise in agricultural and fishing input costs and the fall in output prices. Only one settlement, Sugozu, reported an improvement in living conditions, relating this to the on-going construction of the Thermal Power Plant, which has provided employment opportunities.

Sources of Livelihood: wage incomes (eg from permanent, non-agricultural employment) contribute only a small proportion of income to the residents and are a main source of income for only 34 of the 200 households surveyed. Fishing is a source of livelihood for at least 60 of the 200 households surveyed, with the majority of fishermen residing within Golovasi, Deveciusagi and Haylazli.

Alternative Sources of Livelihood: alternative sources of income besides agriculture, fishing and husbandry, include trade and semi-skilled irregular jobs, such as driving and operating heavy construction machines (eg Karatepe, Karayilan, and Sugozu).

Levels of Employment (employment status)*:* unemployment levels for the survey settlements are deceptively low. In reality, only approximately 17% have salaried permanent positions. The vast majority are self-employed in natural resource based activities (farming or fishing). These activities are vulnerable to environmental and economic fluctuations (varying prices for goods produced).

Sources of Employment*:* fishing, agriculture, animal husbandry and utilities are the main activities sectors that employ people's time within the survey area. Fishing is the main employment source for 77 of 288 (27%) respondents including: 23% of respondents in Incirli; 31% of respondents in Golovasi; 44% of respondents in Haylazli; and 58% of respondents in Deveciusagi. Where fishing is a main source of income, most of the residents are self-employed and generally own or part-own fishing boats. Tourism does not appear to be an important source of employment in the area, although trade is the second most common source of employment for some residents in the settlements of Golovasi, Incirli, Sugozu, Hamzali, Haylazli and Deveciusagi.

Previous Construction Experience[1]: respondents in both the neighbouring and non-neighbouring settlements reported semi-skilled and unskilled experience on previous construction projects. The highest totals per settlement were recorded for Golovasi and Sugozu.

Acceptance Rates: more than 70% of respondents from the neighbouring settlements would accept temporary employment, although these figures vary for non-neighbouring settlements. In Karatepe, however, there is a strong preference for permanent employment partly due to its proximity to the new facility, where it is recognised that there will be some opportunities for employment.

10.13.2 Levels of income and wealth

The following conclusions can be drawn with regard to levels of financial and economic assets.

- **Income levels**: the average per capita annual household income in the marine terminal survey area is 3,184 million TL (1,990 USD)[2] (see Figure 10.22). This figure is

[1] Previous construction experience is defined as any previous construction experience, whether as skilled, semi-skilled or unskilled workers. Levels of experience are not considered in this definition.
[2] Rate of Exchange: 1million TL = 1.6 USD January 2002

marginally above the average for Adana province as a whole (2,924 million TL or 1,246 USD) and the minimum wage of 2,220 million TL for over 16 year olds and 1,1187 million TL for under 16's[1]. Residents in Sugozu have almost double the average survey area income (6,328 million TL or 3,955 USD) due to their relative dependency on wage income and pensions providing both a regular and permanent income for households. Residents from Sahil Sitesi and Haylazli also have income levels above the provincial average (3,844 m TL or 2,402 USD) and 3,722 m TL or 2,326 USD respectively). Incomes are significantly lower in Karatepe (55% less than the average for the marine terminal area), corresponding with the high unemployment levels for this settlement (18% unemployment compared to the national average for Turkey of 8.5%[2]).

- **Income distribution:** the highest inequality in income distribution[3] is found in Sahil Sitesi, potentially due to the different incomes between secondary homeowners and permanent residents. Karatepe exhibits the second highest inequality in income distribution, possibly because a high proportion of residents are unemployed. Sugozu also exhibits an unequal distribution of income substantiated by the consultation findings that suggested a small number of large farms and rich landlords[4].

- **Income fluctuations:** approximately 40% of households in all the neighbouring settlements, with the exception of Sahil Sitesi, stated that average incomes fluctuated throughout the year, peaking between June and August (corresponding to peak agricultural harvest times) and falling between December and January. The non-neighbouring settlements, particularly Deveciusagi and Haylazli, also exhibit monthly fluctuations in income, with high-income months being September and October and low-income months being December and January. Both are dependent on fishing and agriculture as their main source of activity.

- **Levels of wealth:** wealth is a measure of both income and assets such as televisions, property and cars. Levels of wealth were calculated using two indices, an Asset Index (AI) and a Composite Asset-Income Index (CAII). These are explained in greater detail in Section [10.13.2]. The settlements show a similar ranking for both indices. Karatepe is the poorest in terms of assets and Hamzali the richest. Sahil Sitesi has a slightly lower asset ranking potentially because secondary homes are less likely to have assets such as televisions because they are not occupied throughout the entire year. Sugozu (more dependent on wage income and pensions) is ranked top in terms of both assets and income.

- **Levels of debt:** approximately 54% of surveyed households in the marine terminal study area are in debt. This is attributed (by 28% of all surveyed households) to a fall in price of agricultural products and (by 15% of households) to general economic conditions (a reference to the current economic crisis in Turkey). The level of debt in the non-neighbouring settlements is higher, explained by the tendency for comparatively richer settlements to obtain credits. Of the neighbouring settlements, Incirli and Karatepe exhibit the lowest levels of debt (44% and 30% respectively), and Golovasi the highest (fishing is one of the main sources of employment) (see Box 10.11*)*. Of the non-neighbouring settlements, households in Deveciusagi have particularly high levels of debt attributed to, a fall in agricultural product prices, general economic conditions and a fall in fish stock.

[1] Argen Employment Agency (30.6.02). The minimum wage changes every 6-12 months according to a Decree operating under the Labour Law 1475. The education age in Turkey is 6 to 14 or in some cases 7 to 15.
[2] State Institute of Statistics (SIS), 2000 Census.
[3] Determined through calculation of standard deviation from the settlement mean.
[4] Although 80% of villagers stated that they own land, the average plot size is relatively low suggesting that the majority do not derive income from this land. The majority of land in Sugozu is state land and only a small proportion privately owned.

Box 10.11 Fishermen Debts

Fishing debts are attributed to the high cost of fishing equipment (by 44% of households surveyed in Golovasi), high petroleum costs in fishing (44% of households), a fall in fish stocks (22% of households) and agricultural prices (22% of households). The debt is generally owed to tradesmen. The high levels of debt among fishermen was corroborated during the settlement meetings where fishermen explained that they purchased equipment from private fishing companies (eg local traders) in the area using money borrowed from the companies and on condition that they sell their fish to these companies.

Source: Local Fishermen from Golovasi, Adana

- **Creditors:** of the total number of households surveyed, 53% reported being in debt. Of these, 53% owe money to the Ziraat Bank and 22% (largely fishermen) to tradesmen. In Golovasi, approximately 58% of indebted households owe money to tradesmen (eg the private fishing companies). The majority of households (90%) in the marine terminal survey area expect to be able to pay off their debt, including 42% of households in the next five years and 32% in the next year. The ability to pay off debt is particularly low in Golovasi where a large proportion of inhabitants are dependent on earnings from fishing - perceived to be an increasingly unreliable form of livelihood. In Incirli and Karatepe, the majority of debt is owed to relatives, as is characteristic of poorer communities.

- **Changes to quality of life:** with the exception of Sugozu, all Muhtars stated that living conditions had deteriorated in the past five years, specifically in settlements dependent on natural resource based activities (farming and fishing). Rising prices of agricultural inputs and a reduction in subsidies, in conjunction with falling agricultural product/output prices, have exacerbated the situation for farmers (and fishermen) already faced with a provincial trend of increasing industrialisation, a local trend of land expropriation and increased marine exclusion zones associated with coastal developments. For Sugozu, living conditions have improved due to job opportunities provided by the on-going construction of the Thermal Power Plant. This is substantiated by its ranking as the 'wealthiest' settlement in the survey area, both in terms of income and assets.

Potential solutions offered by Muhtars to counter this downturn include enhancement of agricultural opportunities (eg increasing levels of agricultural credit, provision of high quality seed and improvement of irrigation facilities) and investment in non-agricultural opportunities for the younger generation.

Figure 10.22 : Average Annual per Capita Household Income (million TL) by Surveyed Settlement in the Marine Terminal (MT) Area

10.13.3 Sources of livelihood

Table 10.20 summarises the key sources of livelihood (both wage income and subsistence) for households surveyed in each settlement. The main findings are that wage incomes contribute only a small proportion of the total income in the survey area (this includes the small proportion of residents from Incirli and Hamzali employed with BOTAŞ). Fishing, agriculture, animal husbandry and pensions are the main sources of income, although the former three activities are also critical for subsistence in the settlements (see Figure 10.23). Traditional income generating-activities are losing their importance (see Box 10.12 and Plate 10.17).

Box 10.12 Traditional Income Generating Activities

Women in Yoruk (an ethnic group from Anatolia) settlements generally weave carpets. Iinhabitants from Karatepe were originally from Yoruk settlements. In Karatepe, women make valuable handmade carpets. And household material. Yet according to older women in Karatepe, young women do not treat this as an income-generating activity and many do not know how to weave.

NB: Multiple responses permitted, therefore percentage exceeds 100

Figure 10.23: Sources of Income for the Surveyed Settlements

Plate 10.17: Traditional Livelihoods – Residents Standing Adjacent to Home-Made Carpets

Table 10.20 Livelihood Sources (Cash Income and Subsistence Goods)

INCOME SOURCE	IMPORTANCE (AS A SOURCE OF INCOME AND SUBSISTENCE) FOR THE NINE SURVEYED SETTLEMENTS (HH = Household)				COMMENT
	High (>59% of HHs surveyed)	Medium (21-59% of HHs surveyed)	Low (< 21% of HHs surveyed)	0% of HHs surveyed	
Wage Income (permanent non agricultural)			Hm ; Ha ; D ; K ; Ky; SS		Wage income (eg from construction firms, industrial activities) varies in importance between settlements. 17% (34 of surveyed HHs) list permanent wages as a main source of income (25% of these are employed in schools and a small proportion with fishing companies). This includes nine (35%) and seven (30%) of HHs in Golovasi and Incirli respectively. Less than 10% of HHs surveyed in Deveciusagi, Haylazli, and Hamzali list wage income as a main income source.
Fishing		D; G; I; Ha	K; SS ; Su	Ky	For many of the residents, fishing is a *'way of life'* not only a source of income. Fishing is a main source of income for: 40% or 12 HHs surveyed in Deveciusagi; 38% or ten surveyed HHs in Golovasi; 30% or seven surveyed HHs surveyed in Incirli; and 37% or 11 HHs surveyed in Haylazli. Fishing for HH consumption is also important in these settlements.
Tourism/ Trade			G; I; Su; Hm; Ha; D; SS	K; Ky	The survey suggests that tourism/ trade is only a main source of income for 16 of the 200 surveyed HHs. In Golovasi and Incirli, 15% (four) and 13% (one) of surveyed HH HHs respectively reported tourism and/ or local retailing for servicing tourists, (eg local convenience stores, the camping ground on the beach front in Incirli) as a main source of income (see Plate 10.18). However, it should be noted that although tourism is not a major source of income, residents in Sahil Sitesi are primarily secondary homeowners and use the location as a retirement/ holiday retreat. There are also recreational facilities at the existing BOTAŞ terminal including a private beach, a guesthouse with approximately 50 rooms and a restaurant. These are only accessible to BOTAŞ employees, their families and guests.

INCOME SOURCE	IMPORTANCE (AS A SOURCE OF INCOME AND SUBSISTENCE) FOR THE NINE SURVEYED SETTLEMENTS (HH = Household)				COMMENT
	High (>59% of HHs surveyed)	Medium (21-59% of HHs surveyed)	Low (< 21% of HHs surveyed)	0% of HHs surveyed	
Food Products	Ky; Su; Hm; Ha	K; D; SS	I ; G		Agriculture is by far the most important source of income for the non-neighbouring settlements: Hamzali (78% or 18 surveyed HHs); Sugozu (76% or 19 HHs); Haylazli (77% or 23 HHs); Karayilan (60% or 9 HHs); and Deveciusagi (47% or 14 HHs. For the neighbouring settlements, 33% or ten surveyed HHs in Karatepe named food production as a main income source, followed by 17% (or four HHs) and 19% (or five surveyed HHs) in both Incirli and Golovasi. All settlements sell cotton in outside markets in varying proportions, but grain is grown primarily for household consumption particularly in Golovasi, Karatepe, Karayilan and Deveciusagi.
Animal Husbandry		I; □K; Hm ;	K; Hm ; D	G ; SS; Ky; Su; Ha	Of all the HHs surveyed (200), only 13 stated that animal husbandry was an important income source. Seven of these HHs were in Incirli and the remainder in Deveciusagi, Karatepe and Hamzali. This figure is low, reflecting the fact that animal husbandry is primarily a subsistence activity. Residents complained of existing shortages of pastureland in the consultation meetings in part due to previous land expropriation.
Pensions		G ; Hm ; Su ; SS	I; K; Ha; D	Ky	36 of the 200 HHs surveyed stated that pensions were a main source of income. This included Golovasi (27% or seven HHs), Sugozu (32% or eight HHs), Hamzali (39% or nine HHs) and Sahil Sitesi (38% or three HHs). The latter is a popular spot for secondary homeowners, particularly pensioners. Many of the residents in the surveyed settlements are retired farmers and depend on the social security institution BAG-KUR or are retired semi-skilled labour dependent on the SSK[1].
Assistance from relatives			I; G; K; Hm; D	Ky; Su; Ha; SS	More than 13% of HHs surveyed in Incirli, Karatepe, and Hamzali stated that help from relatives was a main source of income. No information was available on where these relatives were based or how they were earning their income.

[1] There are three pension schemes in Turkey: 1) Emekli Sandigi the retirement fund for civil servants; 2) Social Security Institutions (SSK) for primarily private and some public workers; and 3) Bagkur (Social Insurance Agency) for employers and the self employed (e.g. farmers, merchants, artisans and tradesmen).

INCOME SOURCE	IMPORTANCE (AS A SOURCE OF INCOME AND SUBSISTENCE) FOR THE NINE SURVEYED SETTLEMENTS (HH = Household)				COMMENT
	High (>59% of HHs surveyed)	Medium (21-59% of HHs surveyed)	Low (< 21% of HHs surveyed)	0% of HHs surveyed	
Rental/ Real estate income			Hm	I; Ha; G; D; K; SS; Ky	Of all the surveyed HHs, income from property rental was only important for one household in Hamzali reflective of the limited and unstructured rental market. During consultation, a handful of secondary homeowners from Sahil Sitesi stated that they would be willing to sell or rent their properties for incoming construction workers.
Social Assistance and Solidarity Encouragement Fund (*Sosyal Dayanisma Fonu*)			D	G; Su; I; Hm; K; Ha; Ky; SS	The Social Assistance and Solidarity Encouragement Fund was only found to be a main source of income for one household in Deveciusagi.

Source: Household Survey 2001

Key to settlements: G = Golovasi; SS = Sahil Sitesi; Hm = Hamzali; Ha = Haylazli; D = Deveciusagi; K = Karatepe; I = Incirli; Kv = Karayilan; Su = Sugozu.

HHs = Households

Plate 10.18: Camp site at Incirli (existing BOTAŞ Jetty in the background)

10.13.4 Levels of employment (employment status)

Table 10.21 summarises the key findings in relation to employment (see Plate B8-10.13). The findings suggest that unemployment levels are low (particularly when compared to urban areas of Adana where in-migration has resulted in high levels of unemployment). However, the vast majority of residents are self-employed, farmers and seasonal workers vulnerable to seasonal and economic fluctuations and *underemployment* [1]. High *underemployment* explains why 29% of households named unemployment, and lack of social security as the priority settlement problem and why, during consultation meetings, high expectations were recorded regarding permanent employment from the new marine terminal development. Unemployment/underemployment was particularly severe in Karatepe, notably among the educated younger generations.

10.13.5 Main sectors of employment

As summarised in Figure 10.24, respondents are primarily engaged in the natural resources (agricultural, animal husbandry, fishing) and utilities sectors. This does not entirely correspond to the main sources of income reviewed earlier in Section 10.13.2, particularly in the case of animal husbandry. For example a high proportion of respondents are engaged in animal husbandry (eg 70% and 80% of households in Karayilan have poultry and cattle) but outputs are used to meet subsistence needs rather than contributing to cash income.

- **Main employment sector:** the findings suggest that settlements can be differentiated into four groups in terms of top employment activities:
  - Fishing: 31% of respondents in Golovasi; 44% of respondents in Haylazli; 58% of respondents in Deveciusagi (See Box 13a and b);
  - Agriculture: [2] 69% of respondents in Sugozu; 82% of respondents in Hamzali; 50% of respondents in Sahil Sitesi;
  - Animal husbandry: 36% of respondents in Karatepe; and 44% of respondents in Karayilan;
  - Utilities: 26% of respondents in Incirli, (mainly at the BOTAŞ site, although this is not a main source of income for this settlement).

  The second most common source of employment is: fishing in Sahil Sitesi and Incirli; agriculture in Karayilan, Haylazli and Deveciusagi; trade (eg shops/crafts) in Golovasi; and 'other' (eg construction, working in the Sugozu Thermal Power Plant construction) in Sugozu, Hamzali and Karatepe.

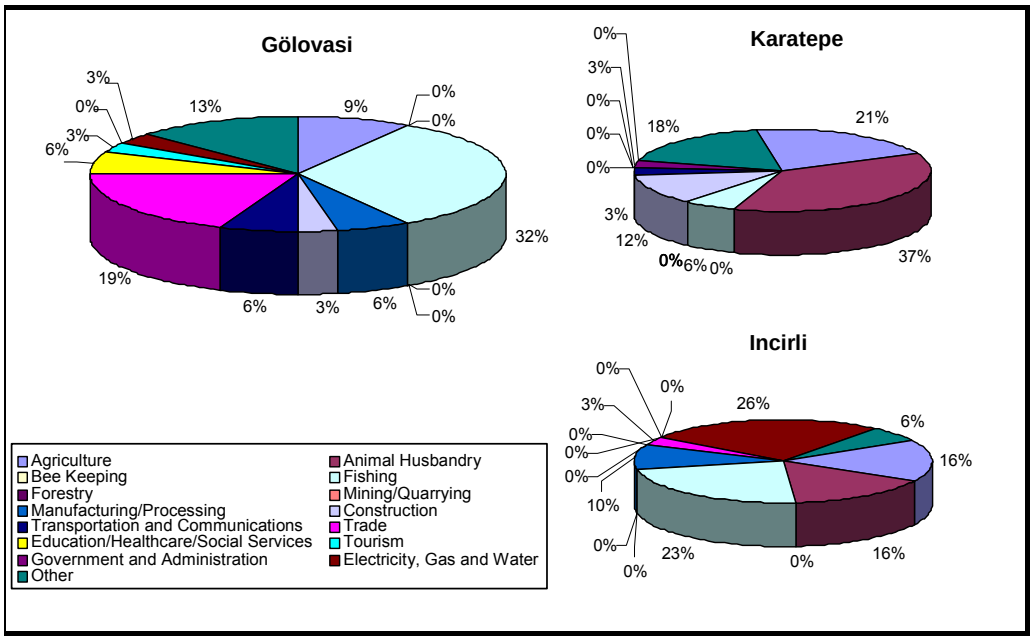
[1] Someone is classified as underemployed if they work for less than 40 hours a week due to: 1) a lack of employment or full time employment; or 2) a shortage of jobs; or 3) they are employed in an activity that does not match their skills set or potential earning capacity (State Institute of Statistics, 2001.

[2] The importance of agriculture as a main employment sector is well below the provincial average of approximately 50% with the exception of Sugozu, Hamzali and Sahil Sitesi. This suggests that the project areas have already been impacted by existing developments, but also the land (volcanic hills only occasionally interrupted by valleys) is less suitable for agriculture than the Cukurova plain, north of the area.

Table 10.21 Employment Status

EMPLOYMENT STATUS	COMMENT
Unemployment	Relatively low rates of unemployment were found in the surveyed settlements area (although still higher than the national average of 8.5% in 2001). The highest levels are found in Karatepe (18%), Golovasi (11%) and Hamzali (19%). In Karatepe, a quarter of all household heads and young adults over 14 are unemployed. It should be noted, however, that unemployment is likely to be under-reported particularly because respondents did not like to be categorised as unemployed. High levels of underemployment also characterise the project area.
Permanent Salaried Jobs (formal employment)	Regular salaried jobs are rare amongst respondents, although slightly more prevalent in the neighbouring settlements - Incirli (9% of respondents work in companies), Golovasi (9% of respondents work in education or for fishing companies) and Karatepe (7%) with main employers including BOTAŞ, fishing companies, schools and the army. It should be noted, however, that the majority of residents who reported having salaried jobs were actually doing informal or casual work and as a result can be considered underemployed.
Self Employed (non farmers)*	The levels of self-employment are 17% in Sahil Sitesi and Deveciusagi, 15% in Haylazli, 12% in Golovasi and 10% in Incirli. A number of these settlements, including Golovasi and Deveciusagi, are dependent on fishing as a source of income and employment. Self-employed fishermen are particularly vulnerable, having run up debts to purchase their own equipment (eg fishing boats).
Farmers	A significant number of respondents in Hamzali are farmers (approximately 21%), although the majority only employ one worker. In Haylazli, 8% of respondents (slightly more than for Hamzali) stated that they employed two or more workers. Both Hamzali and Haylazli are associated with commercial agriculture.
Unpaid Family Worker **	Relatively few respondents identified themselves as unpaid family workers.
Seasonal Employee	These were the highest in Karayilan (5%), Deveciusagi (5%) and Haylazli (4%), correlating with the higher levels of income fluctuation reported for these settlements (see Section 10.14.2).
Other	This group made up a large proportion of respondents and included students, retired respondents and housewives. The majority of women identified themselves as housewives although may undertake either income or subsistence family work (eg working in the fields, or tending the household garden or poultry). The main exceptions were Hamzali where 5% of women stated that they had regular jobs, Sahil Sitesi where a quarter defined themselves as self-employed, and Incirli and Karatepe where women are employed in 'other' areas (eg at BOTAŞ as cleaners/ caterers).

* 'Self employed' individuals earn a cash living from his/ her non agricultural activity
** 'Family workers' are defined as unpaid family members (excluding housewives) who participate in helping secure a living (cash and subsistence) for the household
Source: Household Survey [Ref xxx]



Source: Household Survey 2001 **[Ref xxx]**

Figure 10.24: Main Sectors of Primary Employment for Surveyed Respondents in the Neighbouring Settlements

- **Dependency:** the findings of the survey and consultation with local fishermen suggest that settlements in the project area are highly dependent on one source of livelihood and if this livelihood opportunity was disrupted there could be severe repercussions. For example, Karatepe and Karayilan are dependent on animal husbandry, and future impacts on pastureland, compounding impacts of previous developments, would have severe implications for sustaining levels of livelihood. In Golovasi, where agricultural land is held in the hands of the minority, a loss of fishing as a source of livelihood would leave residents with limited options for securing a livelihood.

Box 10.13 Fishing as a Source of Employment

Importance of Fishing: fishing is *one of two* main sources of *income* for 54 (27%) of the 200 households surveyed, a *source* of *income* for 60 of the 200 households surveyed and the main source of *employment* for 77 of 288 respondents. Golovasi[1], with a harbour approximately 700 m from the proposed marine terminal jetty, has the highest number of surveyed households in the neighbouring settlements (38% or ten households) involved in fishing as one of two main sources of income, followed by Incirli[2]. Fishing is the *main* source of *income* for 33% of households in Golovasi and one of the two main sources for 80% and 37% of households in Deveciusagi and Haylazli respectively. However, the latter two are more distant from the planned marine terminal and not expected to be substantially impacted. In addition, there is indirect employment from fishing (eg unemployed youth in Golovasi are paid to repair nets and boats). Only in the non-neighbouring settlements of Karayilan, Sugozu and Hamzali were there no surveyed households involved in fishing (see Figure 10.25).

Numbers of Boats Registered: according to the official records held in the Yumurtalik sub-governorship, 30 fishing boats are registered in Golovasi (although local fishermen state that there are 50 boats in the settlement) and eight boats are registered to Incirli Sea Security. Only those boats that are officially permitted are allowed to fish in the Incirli area.

Employment Status: of the eight households surveyed in Golovasi that fish, three work for fishing companies. The other five and all surveyed fishermen in Incirli and Karatepe are self-employed.

Use of Fish: generally, fishermen use 1-2kg of fish for their own household consumption per day. Some fishermen from Golovasi and Incirli sell their catches either within the settlement or to local traders in Yumurtalik (Plate 10.20).

Box 10.14 Fishing as a Source of Employment (Continued)

Fishing Costs and Revenues: the average fishing costs for all fishing households surveyed varies from 100 million to 667 million TL[3] (62 to 417 USD)[4]. Average monthly costs for fishing mostly comprise fuel, the cost of which was found to vary hugely between households (from 43 million to 333 million TL [27 to 208 USD] depending on the scale of household activities). Generally, new nets cost around 100 million TL (80-90 million TL for the raw material for each net and 10 million TL for the labour, most of whom are women). Boats are imported from the Black Sea region and cost between 2-8 billion TL depending on size (1,250 to 5,000 million USD). The cost of raw materials for fishing is in general regarded as expensive, with the price of the nets indexed to the USD, but sold in Turkish Lira. Interest rates for equipment are also high. Average revenue for all fishing households surveyed varies from 100 million TL (62 USD) to 272 million TL (170 USD)[5]. Local fishermen reported to earn as profit, on average only 20-25%of what they sell annually. For the three families working for fishing companies in Golovasi, monthly wages were found to range from 83 to 150 million TL (52 to 94 USD). These wages are below the minimum wage (222 million TL) (139 USD) for individuals above 16 years of age.

Fishing Regardless of Low Revenues Earned: despite the fact that revenues from fishing are

[1] Includes the settlement of Sahil Sitesi.
[2] For the purposes of this section of the baseline description, the focus will be on fishing activities in Golovasi (includes Sahil Sitesi) and Incirli, unless where information on other settlements has relevance to this assessment.
[3] Rate of Exchange: 1 million TL = USD 1.60, January 2002
[4] It should be noted that fishermen found it difficult to give exact figures for costs and revenues associated with fishing.
[5] The Mayor of Yumurtalik Municipality suggested that fishermen generally earn between 100-150 million TL per month.

reasons were given:

- lack of alternative livelihoods and lack of skills to undertake other activities, particularly as the majority of fishermen are middle aged;
- large debts to local traders that, according to social norms, would be undesirable to leave for their children to pay off;
- expectations that there could still be opportunities to profit from fishing in the future;
- most fishermen enjoy fishing as a way of life. It has been a family business for generations and they do not want to change their way of life.

In view of their self-employed status, debt owed to fishing companies, dependency on expensive inputs (particularly fuel) and a decline in catches, fishermen in the survey area are particularly susceptible to additional negative impacts from future developments.

Studies to investigate the importance of fishing as a form of livelihood and to assess the potential impacts of the BTC Marine Terminal, (particularly the exclusion and manoeuvring zones of the BTC Jetty) are ongoing. To date, studies have focused primarily on the collection of data in the form of questionnaires with households and Muhtars from settlements in the vicinity of the Marine Terminal. This data collection includes the soliciting of information from local fishermen, particularly those living in the settlements of Golovasi, Sahil Sitesi and Incirli.

As a result, the findings reported in this section reflect the opinions and concerns of these stakeholders. This section will thus be added to as additional information becomes available. The overall studies will be completed and the results disclosed in parallel with the end of disclosure for the BTC Project.

Alternative Livelihoods for Fishermen: As an alternative income-generating activity, some of the fishermen rent their boats to amateur fishermen – but this is usually limited to summer and approximately 8-10 times per year. Fishermen also take tourists to the ancient castle (remains of Aegea ancient city) located on an island off the coast called *Kiz Kalesi* (Plate 10.21). Finally, between 10-15 fishermen in the settlement rent approximately 10 hectares of land and produce wheat and cotton as a secondary activity.
NOTE: See Section 11 for further information on fishing patterns, catch and dependency.

Plate 10.21 Kiz Kalesi Tourist Island

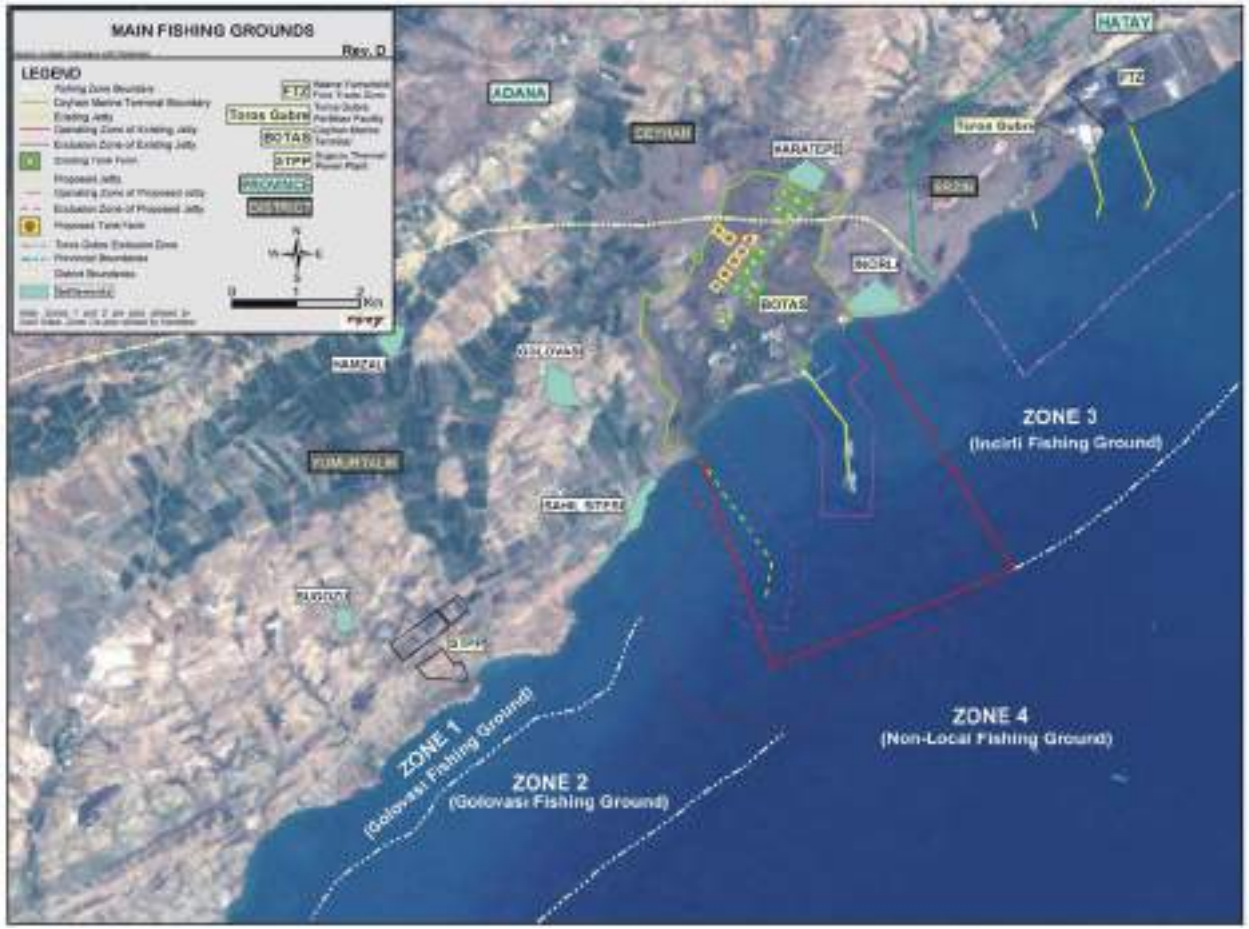

Figure 10.26 Main Fishing Grounds Map

10.13.6 Availability of construction skills and pipeline experience

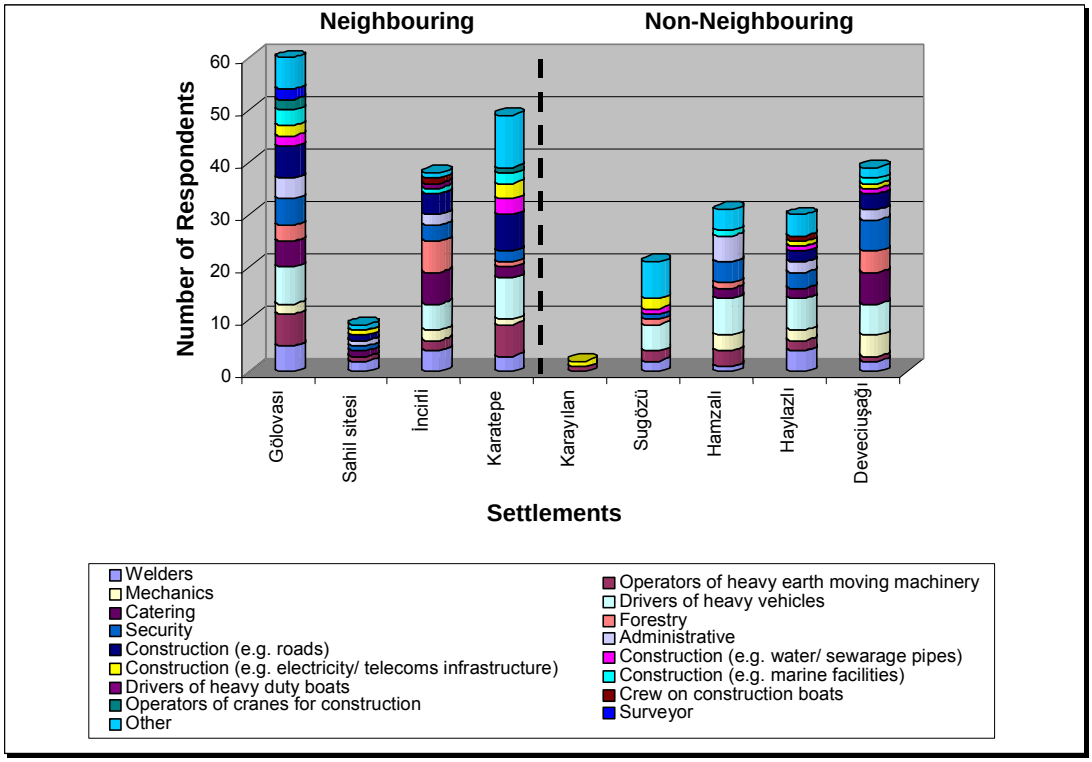
There is potential for recruitment of semi-skilled and unskilled workers primarily during construction. In order to ascertain the availability of construction skills and experience, respondents were asked to list their available skills, previous construction experience and availability for temporary employment. The findings indicate that there is an existing pool of labour with construction experience.

10.13.6.1 Neighbouring settlements

The most widely available personnel with relevant construction skills in the neighbouring settlements are: drivers of heavy vehicles (15 of 64 respondents); drivers of heavy earth moving machinery (15); road construction workers (14 of 64 respondents); catering (eight); and welders (ten) (see Figure 10.27). Golovasi recorded the largest number of surveyed respondents with previous construction experience. 46% (12 of 26 respondents) from Golovasi stated that they had previous construction experience compared with 30% (nine respondents), 22% (five respondents) and 38% (three respondents) in Karatepe, Incirli, and Sahil Sitesi respectively (see Figure 10.28).

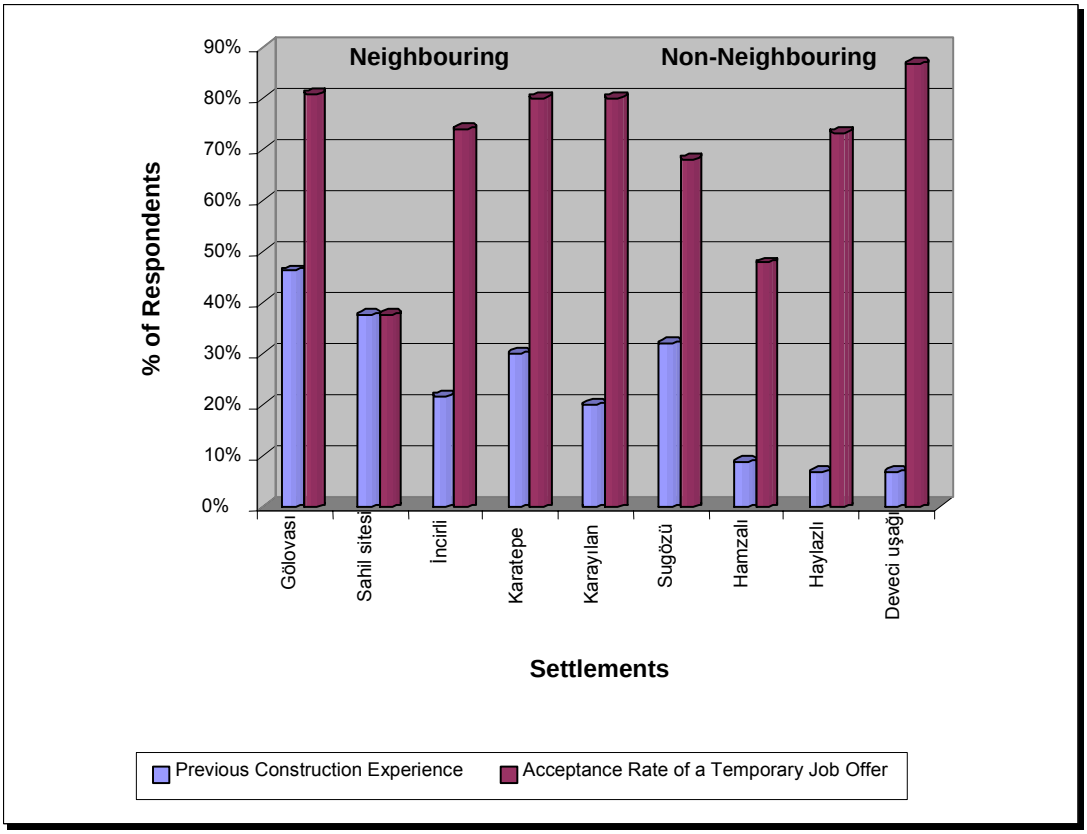
10.13.6.2 Non-neighbouring settlements

- The most widely available skills in the non-neighbouring settlements are: drivers of heavy vehicles (29 of 136 respondents); security guards (17 of 136); catering staff (16 of 136) and welders (13 of 136) (Figure 10.27). Respondents from Sugozu have significantly more construction experience than other non-neighbouring settlements, correlating with employment in the constitution of Sugozu Power Plant. 20% (five respondents) have had experience driving heavy vehicles, 8% (two respondents) experience of using earth moving heavy machinery, 8% (five) welding, 8% (five) utilities construction, and 28% (seven) a range of ‘other’ useful construction skills.



Source: Settlement Survey 2001 **[Ref xxx]**

Figure 10.27 Available Skills in Surveyed Settlements in the Marine Terminal Area



Source: Household Survey 2001

Figure 10.28 Previous Construction Experience in the Surveyed Settlements

10.13.7 Acceptance of temporary employment

Acceptance of temporary employment is a potential proxy for 'underemployment' because it indicates that respondents are not fully utilised in their current occupation. Approximately 80% of surveyed respondents in both Golovasi and Karatepe and 74% in Incirli would accept a temporary job offer. These figures are high, potentially because many of the activities carried out by residents of these settlements are seasonal freeing up respondents for additional work. Residents from Karatepe have very high expectations of permanent employment and have educated younger generations with the expectation of employment from BOTAŞ. Acceptance rates are not evenly distributed throughout the non-neighbouring settlements. The survey suggests that residents in Karayilan and Deveciusagi have significantly higher acceptance rates, possibly because dominant economic activities in these settlements are seasonal activities (animal husbandry in the former and fishing in the latter), freeing up residents for part of the year.

Table 10.22 Summary of Livelihood, Employment and Skills

SETTLEMENT	INCOME RANKING *	ASSET RANKING*	INCOME & ASSET RANKING*	MAIN LIVELIHOOD SOURCE**	WAGE INCOME (% respondents) ***	MAIN EMPLOYMENT SECTOR ****	SECOND MAIN EMPLOYMENT SECTOR ****	% UNEM-PLOYED RESPONDENTS *****	PREVIOUS CONSTRUCTION EXPERIENCE (% respondents)

10.14 INFRASTRUCTURE, UTILITIES AND SERVICES

10.14.1 Overview

Although the new development will be largely self sufficient in terms of telecommunications, energy, water supplies, sewage treatment and waste disposal (as it will utilise existing infrastructure and services in the BOTAŞ property), the Project will use local roads, access

some energy and water supplies from existing local municipal supplies (where consumption does not impact upon local needs). Gradual in-migration, as a result of industrialisation in the Iskenderun Gulf area, will also place additional pressure on existing services and infrastructure.

This section therefore reviews the availability of existing infrastructure and services, particularly in the neighbouring settlements. An understanding of the availability of services and infrastructure also allows for an analysis of the potential impacts associated with an increase in population numbers in the survey area. Background to the provision of infrastructure and services is available in Section 5 of the report.

Box 10.15 provides an overview of the availability and quality of infrastructure and services in the BTC Marine Terminal area. This is followed by a more detailed review of provision.

Box 10.15 Overview of Infrastructure and Service Availability and Quality

Overall: the settlements in the survey area can no longer be considered as traditional (ie solely subsistence based) and are in the process of changing from an agrarian to a more industrial based economy. In spite of this change, housing and infrastructure are in poor condition. In fact, 47% of households stated that infrastructure (particularly low quality roads, insufficient health, education and waste disposal systems and water supply) was the major problem in their settlement.

Infrastructure: all households surveyed (with one exception) receive electricity, although almost half of households surveyed receive irregular supply. Just over three quarters of households receive piped water, although 55% receive an irregular supply. Only 22% of households surveyed have their sewage collected by the municipality. Only 29% of households (located in Incirli, Karatepe and Karayilan) have access to a formal (ie municipality run) disposal system. However, 81% of surveyed households have a telephone, and although there is a mobile network, relatively few respondents have mobile phones. The roads linking settlements and within settlements although generally surfaced with asphalt, are on the whole considered by surveyed Muhtars to be of low quality and in poor condition.

Health: there are no health centres in any of the settlements, and although nurses and midwives visit all surveyed settlements, the health services provided were reported to be unsatisfactory by the majority of households in the neighbouring settlements. A relatively high proportion of households stated that one of their members had required hospital treatment in the past year (63% of households surveyed in Golovasi, 67% of households in Sugozu, and 60% of households from Deveciusagi).

Education: all children between the ages of 6 – 15 (the age of compulsory education) from the surveyed households currently attend school. Approximately half the surveyed adults have attained at least primary school qualifications, 12% have gained both primary and secondary education and 3% of respondents have university qualifications.

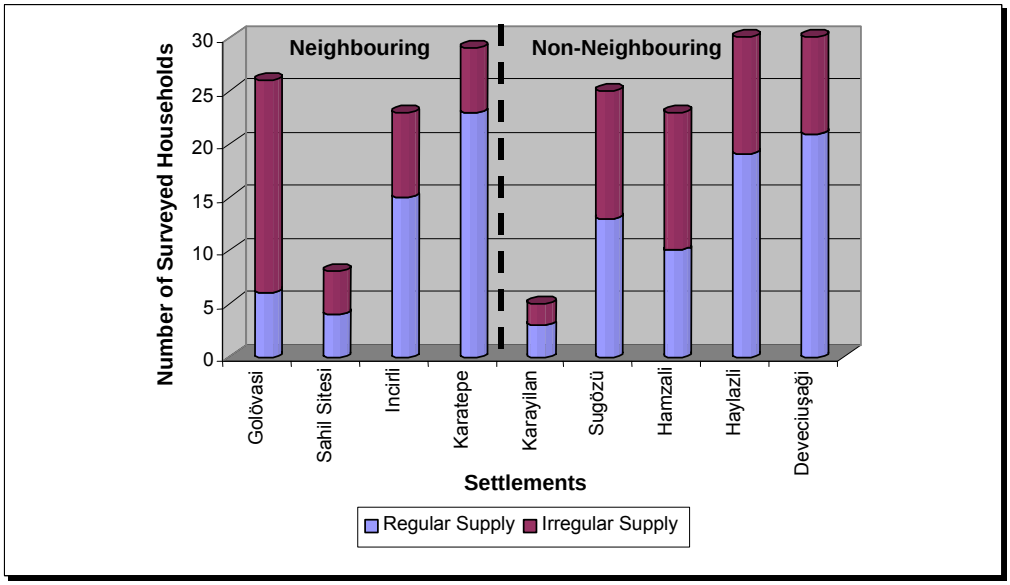
Other Services: other services are limited to coffee houses in Golovasi, Incirli, Hamzali, Haylazli, Sugozu and Deveciusagi, convenience shops and restaurants. There are no other services such as fire or police services.

10.14.2 Services, utilities and physical infrastructure

10.14.2.1 Electricity

All houses surveyed (with the exception of one house in Karatepe) receive electricity and generally use it for lighting. Of the 199 surveyed households with electricity, 43% experience an irregular power supply caused by frequent power cuts (see Plate 10.22 and Figure 10.29).

Plate 10.22 Electricity Cables in Incirli



Source: Household Survey 2001

Figure 10.29 Electricity Supply for Surveyed Households in Surveyed Settlements

10.14.2.2 Alternative energy sources

A wide range of alternative energy sources is available in the surveyed settlements including, solar energy, bottled gas, coal, wood and dung. In general: coal, bought wood and cut wood are used for heating (the former because it is widely available and effective, and wood because it is cheap); bottled gas for cooking (because it is more effective and easily available); natural solar power for heating hot water (primarily because it is cheap); and dung as a source of fuel (because it is free and easily obtained particularly for the 38% of households with cattle).

10.14.2.3 Water

In Turkey, water pipes are primarily constructed by the State (although villagers may contribute to construction) and depending on the location and source of the water, settlements will either be charged (if the State transports water from a dam or other source to the settlement) or provided with water for free. The latter circumstance arises if a settlement has a water source, and the State provides the pipe. Piped water (for drinking, cooking, bathing etc) is received by 153 (76%) of the 200 surveyed households of these, 55% experience irregular supply including all households surveyed in Haylazli, Golovasi and Karatepe.

10.14.2.4 Alternative water sources

For the 47 surveyed households without centrally distributed piped water, the following alternative sources are used: 1) private wells; 2) settlement fountains (12 households); 3) private water depots (28 households); 4) water carried by tankers from nearby settlements (44 households); and 5) in the case of Karatepe, the residents (working for the Toros Gubre Fertiliser Facility) collect tanked water from within the company zone (see Plate 10.23).

Plate 10.23 Delivery of Water to Karatepe, Adana

Box 10.16 Water Shortages

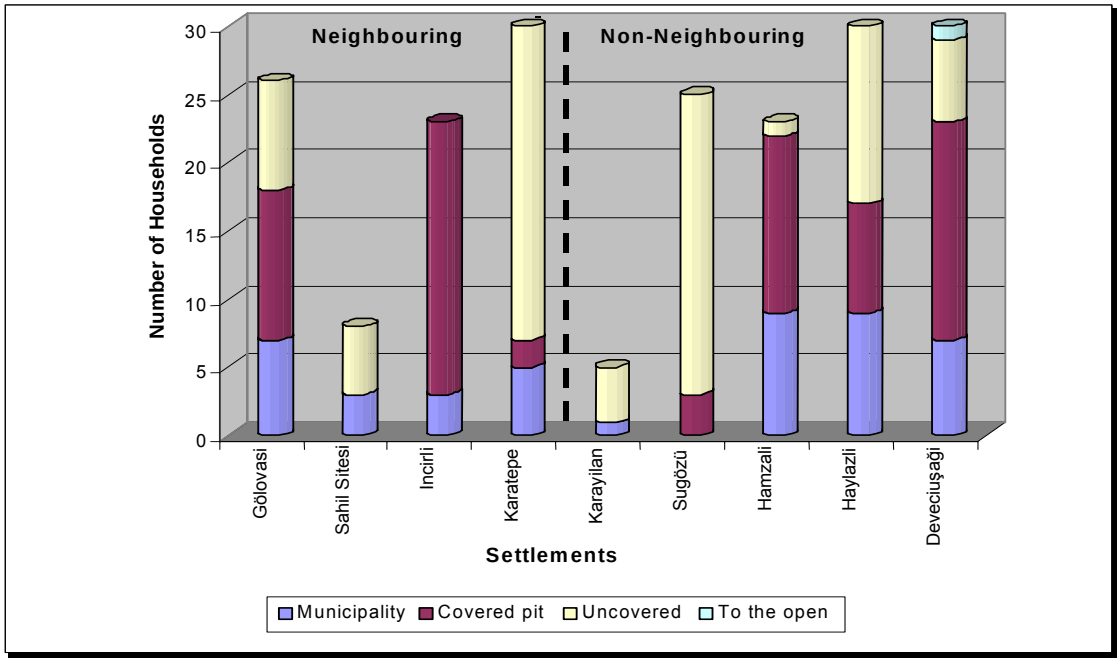
An important concern for inhabitants in the marine terminal area is the lack of water. Residents from Karatepe claimed that the water they use is unhealthy and inadequate both for drinking and engaging in greenhouse/vegetable production.

Source: Residents from Karatepe, Adana

10.14.2.5 Sewage

The disposal of sewage is a huge problem in Turkey. This is reflected in the surveyed settlements where there is no formal piped sewerage system for the surveyed settlements (see Figure 10.30). Forty four of the 200 surveyed households (22%) have their sewage collected and disposed of by their local municipality who regularly empty the pits with trucks. The remainder (including 100% of households in Sugozu) have to use their own means to dispose of household sewage, notably in covered or uncovered pits. All surveyed households in Sugozu

dispose of their sewage privately. The Mayor of Yumurtalik stated that sewage disposal was a particular problem for residents of the summer houses/ secondary homes in Sahil Sitesi.

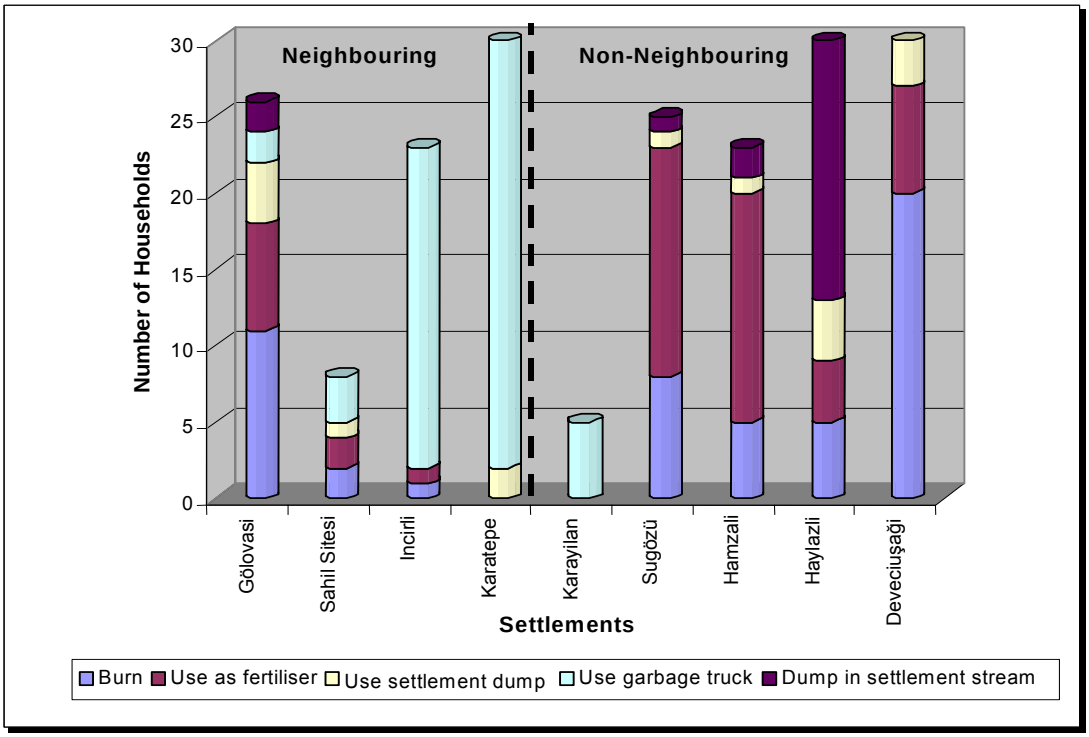


Source: Household Survey 2001

Figure 10.30: Methods of Sewage Disposal in Surveyed Settlements

10.14.2.6 Waste disposal

Of the 200 surveyed households, only 29% of households reported access to a formal (municipality run) disposal system (municipal trucks collect the waste). These households are located in Incirli, Karatepe and Karayilan. The remainder rely on private means of disposal. The household survey uncovered a number of alternative methods for waste disposal, including burning and dumping waste into a settlement dump or nearby streams (see Figure 10.31).



Source: Household Survey 2001

Figure 10.31 Methods of Waste Disposal in Surveyed Settlements

10.14.2.7 Telephones

Of the 200 households surveyed, 162 households (81%) have a telephone. Karatepe and Deveciusagi have the highest proportion of surveyed households owning telephones (77% and 70% respectively). A mobile telephone network covers all the neighbouring settlements. Only 20%, 5% and 5% of respondents from Golovasi, Incirli and Karatepe have mobile telephones – considered a luxury in Turkey.

10.14.2.8 Roads

Observations suggest that the roads in the vicinity of the terminal are in better condition than in many rural areas of Turkey. New roads both within and linking settlements have been constructed within the last five years through many settlements in the vicinity of the BTC Marine Terminal site (although not at Hamzali, Haylazli and Deveciusagi). Consultation suggests that no new roads are planned in the vicinity of the settlements of Golovasi or Incirli. All roads are narrow and the asphalt is generally of low quality and, therefore, prone to wear-and-tear. Local residents have expectations that road will shortly be improved by the government or Marine Terminal operators/contractors. There is significant local tourist trade in the summertime, with considerably increased traffic flows on local roads. This increase in traffic in the summer will coincide with the preferred period for construction activities. Other significant seasonal activities include harvesting, which occurs from May to September. There is a main coastal highway road to the BOTAŞ Dortyol Marine Terminal and the nearby LPG facility. A new highway running north-south is currently being constructed east of Karatepe and Incirli. This would potentially be a viable route to the BOTAŞ property and would remove pressure from existing roads.

10.14.3 Summary of local infrastructure

Table 10.23 below summarises infrastructure provision by surveyed settlement.

Table 10.23 Summary of Infrastructure in the Project Area

SETTLEMENT	ELECTRICITY		WATER		SEWAGE DISPOSAL		WASTE DISPOSAL		TELEPHONE	
(number of households surveyed)[1]	Reg. *	Irreg. *	Reg.	Irreg.	Municipality **	Private	Trucks ***	Private	Yes	No
Golovasi (26)	6	20	6	18	7	10	2	24	22	4
Sahil Sitesi (8)	4	4	0	6	3	0	3	5	6	2
Incirli (23)	15	8	14	8	3	20	21	2	20	4
Karatepe (30)	23	6	12	16	5	25	28	2	21	9
Karayilan (5)	3	2	2	3	1	4	5	0	4	1
Hamzali (23)	10	13	16	6	9	13	0	23	22	1
Haylazli (30)	19	11	0	23	9	21	0	30	26	4
Sugozu (25)	13	12	18	5	0	25	0	25	22	3
Deveciusagi (30)	21	9	0	6	7	23	0	30	24	6
TOTAL	**114**	**86**	**68**	**85**	**44**	**150**	**59**	**141**	**167**	**34**

* *Reg*.= regular supply; *Irreg*.= irregular supply.
** *Municipality* refers to sewage emptied and dumped by municipalities; *Private* refers to sewage emptied and dumped by households in various ways
*** *Trucks,* refers to waste collected by trucks; *Private* refers to household collection and disposal by private means eg in nearby streams.
Source: Household questionnaire

10.14.4 Health levels and services

10.14.4.1 Health Levels

Section 5 provides background information on the health situation in Turkey. The survey revealed no major contagious diseases for the surveyed settlements. However, a relatively high proportion of households stated that one of their members had required hospital treatment in the past year (63% of households surveyed in Golovasi, 67% of households in Sugozu, and 60% of households from Deveciusagi). There is a high incidence of heart and pulmonary illness, particularly in Karatepe are fishermen in Golovasi complained that fishing gave them back problems. Limited additional inferences can be made.

10.14.4.2 Causes of poor health

Causes of poor health included insufficient health care services (mentioned by respondents in four of the surveyed settlements); poor quality water (four settlements); poor diets (three settlements); poverty (two settlements); and insufficient sanitary conditions (two settlements). Old age was also raised as a common cause of poor health.

[2] Health services are provided free for State employed individuals (although occasionally a small fee is required). It is obligatory for private companies to pay for health insurance and treatment for their employees but this is not common. BAG-KUR is the main pensions/ health service covering self-employed individuals living in the rural areas.

10.14.4.3 Health services

There are no health centres in any of the settlements. This was reported as one of the priority problems faced by surveyed settlements. Nurses visit all settlements to provide health services (no details are available on numbers or regularity of visits). The shortage of midwives and overall poor health services were reported to be unsatisfactory by the majority of households in the neighbouring settlements. As a result, residents tend to use the health facilities in Ceyhan district or Kurtkulagi town.

10.14.5 Educational levels and services

10.14.5.1 Education qualifications

All education is free in Turkey and compulsory for children between six and 14. Households have to pay for uniforms (although the State may provide subsidies) and stationery. All children between these ages from the surveyed households currently attend school. Approximately half the surveyed population have attained at least primary school qualifications, 12% have gained both primary and secondary education and 3% of respondents university qualifications (see Table 10.24). Three of the five university educated respondents come from Golovasi.

10.14.5.2 Literacy levels

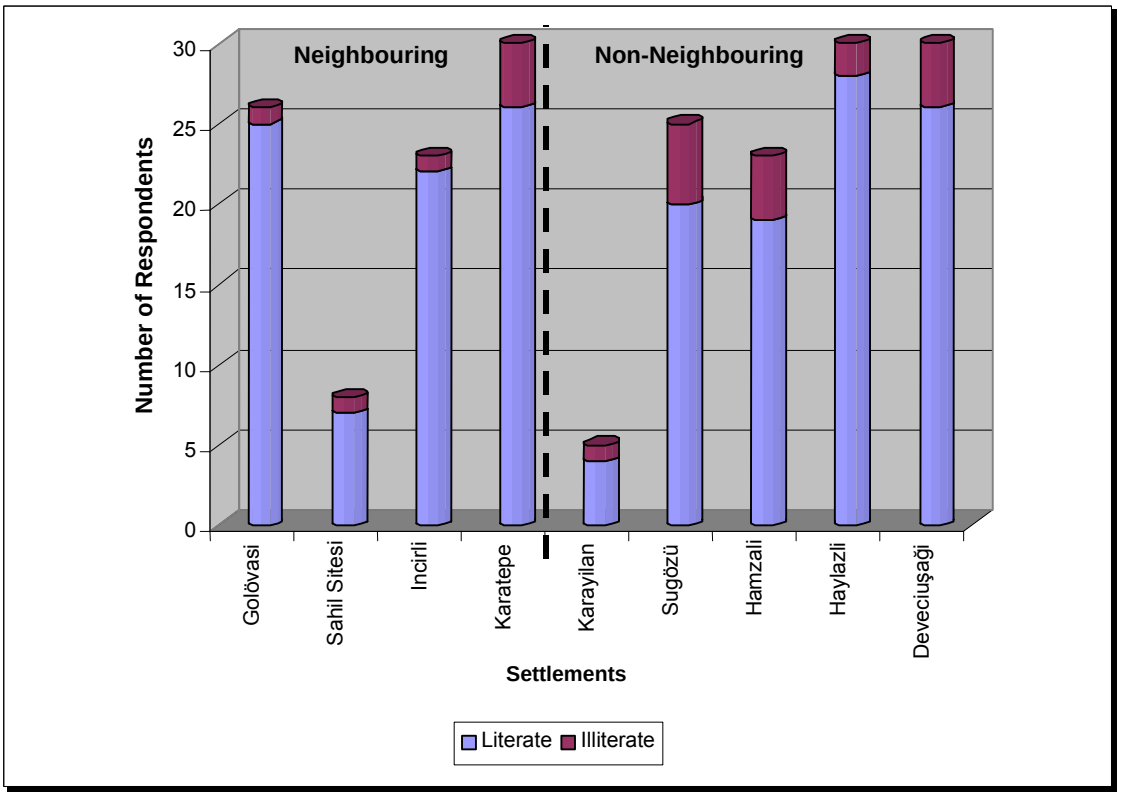
At least 80% of inhabitants in each of the surveyed settlements are literate (see Figure 10.32). There seems to be limited correlation between the availability of primary schools (and teacher/ student ratios) with literacy rates. No acute gender discrimination is evident, and the findings suggest that the inhabitants have a 'liberal' attitude particularly towards female education, a view more prevalent in the more 'developed' provinces such as Adana.

Table 10.24 Education Levels of Respondents by Settlements[1]

SETTLEMENT	NO FORMAL EDUCATION	PRIMARY SCHOOL	SECONDARY SCHOOL	HIGH SCHOOL	UNIVERSITY
Golovasi (26)	1	12	7	3	3
Sahil Sitesi (8)	2	2	1	3	0
Incirli (23)	4	12	1	6	0
Karatepe (30)	5	19	2	4	0
Karayilan	1	4	0	0	0
Hamzali (23)	4	14	2	3	0
Haylazli (30)	3	14	5	7	1
Sugozu (25)	8	9	2	5	1
Deveciusagi (30)	4	22	2	2	0
Total (195)	**32**	**108**	**22***	**33**	**5**

Note: The figures in this table are cumulative (eg 22 respondents have attained secondary *and* primary education)
Source: Household Survey 2001 [Ref xxx]

[1] Until recently, compulsory primary school education was only five years, followed by secondary education of three years and high school education of three years. Now the length of compulsory education has increased to eight years and is followed by high school (which is not compulsory).



Source: Household Survey 2001

Figure 10.32 Literacy Levels in Surveyed Settlements

10.14.5.3 Education facilities

The two largest surveyed settlements of Golovasi and Sugozu, plus Haylazli and Deveciusagi, all have a primary school (all four ranked within the top five of the surveyed settlements in terms of income levels). None of the settlements have a high school. Children go to the nearest settlement or town if there is no primary school or high school within their settlement. For Incirli, for example, the closest primary school is 10km away. For Karatepe, the closest primary and high school are 2km and 20km away respectively. The nearest high school for the students of Golovasi is 25km away[1].

10.14.5.4 Numbers of teachers

The teacher to pupil ratio varies between settlements and is highest in Deveciusagi (40 students per teacher) and lowest in Hamzali (six students per teacher). In Turkey, the average is 26 pupils to each teacher [2] although this varies depending on whether the school is located in a rural/urban or poor/affluent setting.

10.14.5.5 School facilities

On the whole school facilities, with the exception of sports facilities, were described as satisfactory by the Muhtar. In Sugozu, the structural condition of the primary school was rated as unsatisfactory by respondents and the availability of education materials/books also poor. In Deveciusagi, the number of teachers (40 students per teacher) is described as very

[1] The Deputy Director of the BOTAŞ facility noted that the BOTAŞ primary school was open to children from nearby settlements. The facility also runs a school bus to secondary schools in Ceyhan and Adana and makes this available to children from Golovasi, Incirli, Hamzali and Karatepe.
[2] Ministry of Education

unsatisfactory, as is the availability of education materials, hygiene and availability of drinking water at school buildings (the main source in the settlements is private wells).

10.14.6 Other social services

According to the surveyed Muhtar, the following conclusions can be drawn:

- The majority of services (eg fire, library, post office, financial, local government, shops, Jandarma office, local security forces, agricultural support services, sports facilities etc) are not available in the surveyed settlements. The nearest services are located in major towns such as Ceyhan.

- All surveyed settlements, with the exception of Karatepe, have coffee houses. All settlements have good market and transport facilities (eg mini-bus services), with the exception of Incirli where the transport facilities are said to be in bad condition.

- The fishing ports at Golovasi/Sahil Sitesi and Deveciusagi are in good condition (see Plate 10.24).

Plate 10.24 Golovasi / Sahil Sitesi Fishing Port, Adana

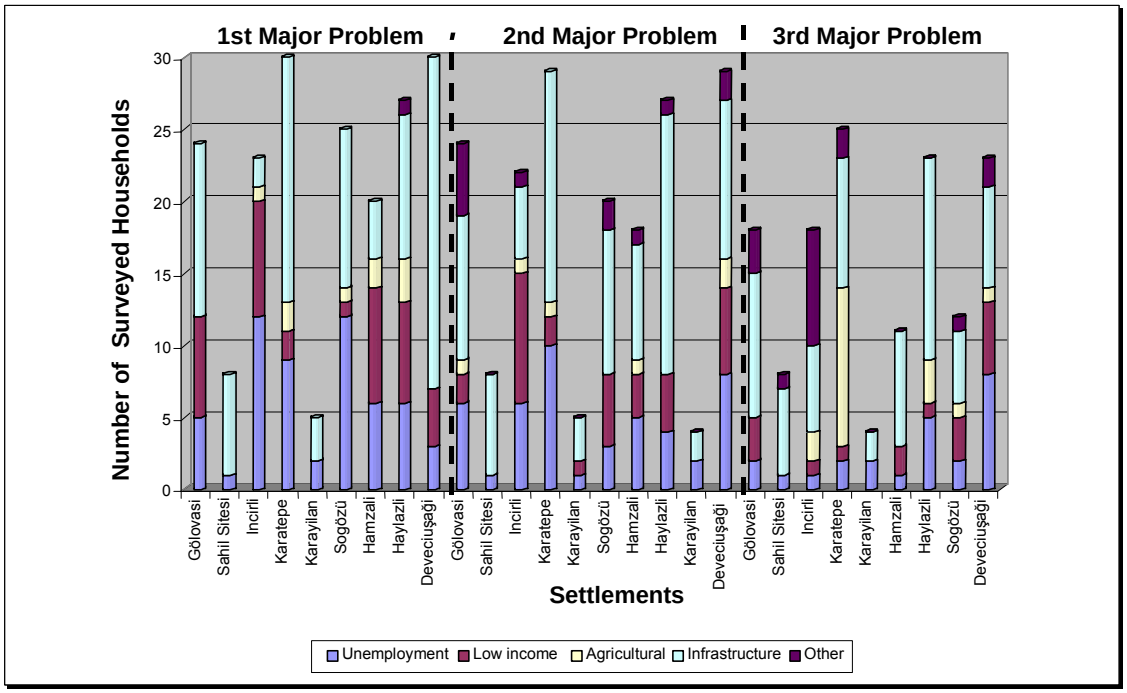
10.14.7 Information sources

Just over half the respondents had reviewed some information about the BTC Project before the consultation meetings. Respondents listed television and settlement meetings as important sources of information, suggesting that these forms of communication are considered for the dissemination of additional information on the BTC Marine Terminal Project.

10.14.8 Main settlement problems

The findings suggest that the main problem in all of the settlements is infrastructure (for 85% of households), followed by unemployment (56% of households), low income[1] (37% of households) and agriculture (9% of households) (see Figure 10.33).

[1] Eg economic hardship experienced by households with no social security net.



Source: Household Survey 2001

Figure 10.33 Top Three Problems in the Surveyed Settlements

10.14.9 Settlement summaries

Livelihoods analysis is a tool for assessing the potential impact of a project on the capital assets of affected communities. It is a valuable way of understanding the baseline conditions, enabling prediction and measurement of impacts. It takes a holistic approach to people's livelihoods and assumes that each person and group of people have a set of 'assets' of various types. These assets are: 1) natural; 2) physical; 3) human; 4) financial; and 5) social.

A new project is likely to affect the size and distribution of these assets. It is therefore useful to assess the current baseline (pre-BTC Marine Terminal) situation of the neighbouring settlements (Golovasi [including Sahil Sitesi], Karatepe and Incirli) of the Project. This helps to define their **current set of assets** so that it is possible to examine how the Project might affect them. An analysis of the livelihood assets for the settlements of Golovasi, Karatepe and Incirli is presented in the Annex B5.

The level of existing assets is summarised in (see Figure 10.34)[1] (ie there are high levels of human capital in Golovasi, but low levels of natural capital). The findings show a mismatch between existing capital levels and dependency (what people need to live) on the difference assets. For example all three neighbouring settlements are dependent on natural capital as a source of livelihood and employment. However, the availability of natural capital is low. This suggests that the neighbouring settlements are extremely vulnerable to future change and if one form of capital (eg natural capital) is reduced by the BTC Marine Terminal, it must be balanced by an increase in another (eg financial capital – employment).

[1] This level of analysis is required here as the Project is directly affecting a main income source (fishing) for a high number of households in Golovasi.

Box 10.17 Conclusions of Livelihood Analysis

- Natural capital*:* this has been recently depleted for all neighbouring settlements due to: 1) recent land expropriation (decreasing availability of agricultural and pasture land); 2) establishment of an exclusion zone for the existing BOTAS Marine Terminal; and 3) competition from non-local fishermen (decreasing fish stock). The situation is compounded by the unequal distribution of land and decreasing fish stocks, which have increased pressure on local resources.
- Human capital*:* this is relatively high in the neighbouring settlements and both male and female inhabitants exhibit high levels of literacy and education. There are also a number of available skills ranging from traditional skills through to construction, although the former (eg carpet weaving and fishing) have become depleted. Relatively low unemployment levels are not truly representative of the situation, and the high potential acceptance of temporary employment, is indicative of significant underemployment.
- Physical capital: there is a shortage of infrastructure and health facilities in the neighbouring settlements. The lack of waste disposal and sewerage systems concomitant with a lack of health facilities has had impacts upon human capital. Other forms of physical capital, including energy, water, transport and communications are relatively well developed.
- Financial capital*:* although non-agricultural permanent wage incomes have become increasingly important, they are still relatively minor. A high proportion of households are in debt (particularly fishermen) and the overall standard of living has deteriorated over the past five years. Generally, respondent earnings are above the minimum wage of 2664 million TL, with the exception of fishermen.
- Social capital*:* the findings indicate relatively tight-knit communities with strong social networks that have experienced a relatively stable demographic situation over the past five years. In-migration was potentially associated with the construction of the existing BOTAŞ marine terminal in the 1970s, but evidence suggests that the study area has experienced a relatively stable demographic composition over the past five years.

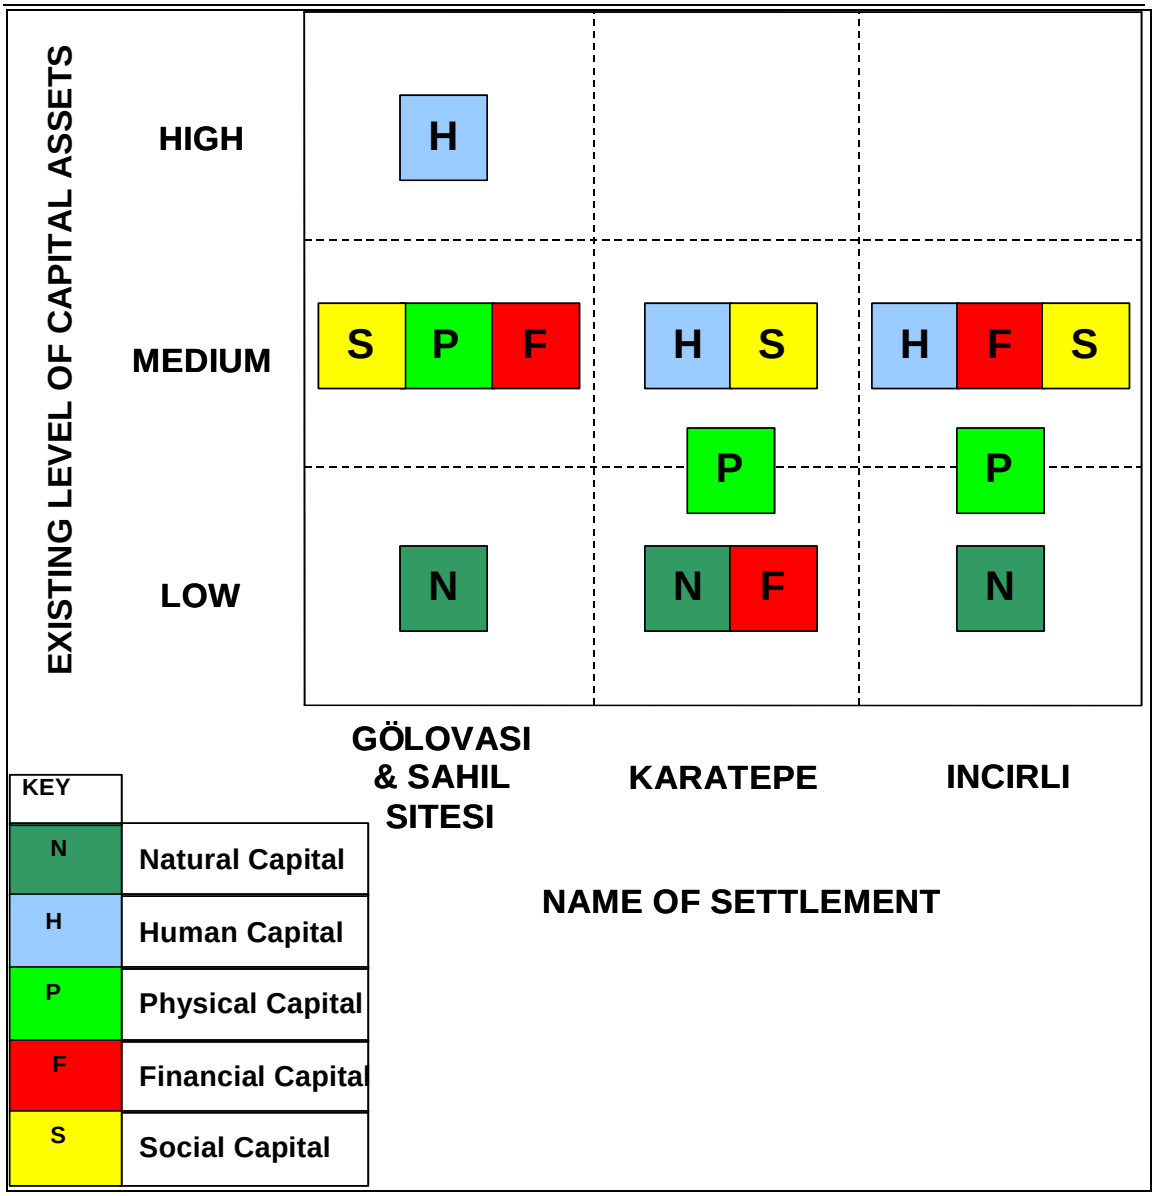


Figure 10.34: Existing Levels of 'Capital' Assets in the Settlements Neighbouring the BTC Marine Terminal Development

10.15 ATTITUDES AND PERCEPTIONS TOWARDS THE MARINE TERMINAL

The majority of residents surveyed are in favour of the jetty and the additional oil tanks (71% or 143 respondents and 75% or 150 respondents respectively) (see Figure 10.1535). For the jetty, this ranges from 91% of respondents in Hamzali (a non fishing settlement) to 52% of residents in Incirli (a fishing settlement). For the oil tanks, this ranges from 100% in Karayilan to 56% of respondents in Incirli. Surprisingly, 97% of respondents from Karatepe (already impacted by the existing tanks) are in favour of the tanks – although this is most likely explained by their high expectations of permanent employment.

Thirty-four respondents had no idea how the Project might impact them negatively. The remaining respondents identified both potential benefits and negative impacts.

- **Perceived benefits of proposed BTC Marine Terminal:** direct employment was raised as the most likely positive benefit by approximately 130 respondents (65%), 20 of whom came from Karatepe and 20 from Sugozu (Figure 10.). In addition, during the consultation meetings, expectations of employment were continually voiced, particularly among the neighbouring settlements. This widespread expectation regarding employment is reflected in the low number of respondents (only 18%) that do not expect any benefit from the proposed project (including 29% of respondents from Deveciusagi).

- **Perceived negative impacts of proposed BTC Marine Terminal:** 45% percent of respondents think that there will be no negative impacts associated with the proposed development (39 responses from neighbouring settlements and 53 from non-neighbouring settlements). However, a number of potential concerns were raised in all settlements (see Figure 10.35 and Figure 10.36). Many of these concerns are based on experiences associated with the existing developments in the area, including the BOTAŞ Marine Terminal.

Further detail on expected benefits and negative impacts raised during the community consultation meetings and questionnaires are provided in Box 10.18 below.

Box 10.18 Perceived Benefits and Problems of the BTC Marine Terminal Development

PERCEIVED BENEFITS

- **Employment:** many respondents expect the BTC Marine Terminal development to result in new opportunities in the region, and bring about indirect employment.
- **Regional development:** a number of respondents expect the BTC Marine Terminal to contribute to industrial development and result in general economic benefits. In general, it was felt that a construction camp would increase commercial activities in the region. Regional and international publicity (as a result of the marine terminal) is also expected to attract development to the region.
- **Infrastructure:** a number of respondents raised the hope that the Project would solve infrastructure problems. For example, respondents mentioned trying to get construction companies to use equipment to improve local infrastructure.
- **Security Services:** a number of respondents commented that the Marine Terminal Project would increase the level of regional security services.

PERCEIVED NEGATIVE IMPACTS

- **Natural Resources:** respondents feel that the BTC Marine Terminal development would increase pressure on existing natural resources.
- **Traffic:** respondents from Golovasi, Karatepe and Hamzali perceived traffic congestion during construction as an impact primarily because their roads are most likely to be impacted.
- **Pollution:** perceived pollution impacts raised by respondents included: increased odour problems in the area; increased sea pollution; increased risk of oil spills and impacts on marine species, along with adverse impacts on drinking water quality.
- **Health and safety:** respondents feel that the marine development could result in an increased risk of fire and oil explosions, which could cause material and human losses.
- **Fishing:** respondents are concerned that the increased exclusion zone would decrease access to fishing ground as well as prevent access to, and use of the fishing port at Sahil Sitesi.
- **Target:** a number of respondents feel that the region could become a target in a possible war
- **Agriculture:** some respondents commented that additional agricultural land might be expropriated as a result of the development.
- **Construction camps and workers:** a number of respondents commented that construction camps could disturb residents (eg through the establishment of relationships between local women and construction workers, through lack of respect for the local values) and as a result of possible hostility or security problems.
- **Employment:** concern was raised that the Project may not employ local people.
- **Migration:** a number of respondents commented that the BTC Marine Terminal would attract in-migration by those seeking jobs, with resultant pressure on, or competition for scarce resources, including employment.
- **Decision making:** some respondents feel that important decisions would be taken by foreign states, and not by Turkey.

11 MARINE TERMINAL - MARINE BASELINE CONDITIONS

11.1 INTRODUCTION

11.1.1 Geographical context

The proposed BTC Marine Terminal is situated in southeast Turkey on the north eastern coast of the Gulf of Iskenderun (see Figure 10.1).

The BTC Marine Terminal development consists of both onshore and offshore facilities. This section describes the offshore environmental and social baseline; the onshore (terrestrial) baseline is dealt with separately in Section 10.

The objectives of baseline data collection are described in Section 10.

11.1.2 Sources of information and methodology

This baseline description is based on a variety of information sources, including desktop studies, consultation with fishermen and fishing organisations and a number of marine surveys undertaken either for the proposed BTC Marine Terminal or for other EIA studies of recent nearby coastal developments. These information sources and surveys include the following:

- existing BOTAŞ Marine Terminal Feasibility Study [Ref 3];
- Marine Surveys I and II – carried out during the winter and spring [Ref 5, Ref 6] comprising chemical and biological sampling at two locations and benthos surveys at six sampling stations near the location of the proposed BTC Jetty;
- Sea Turtle Survey Report [Ref 23];
- Geology and Geomorphology Study for the Existing BOTAŞ Marine Terminal [Ref 8];
- Geohazard Study for the Existing BOTAŞ Marine Terminal [Ref 7];
- winter Benthic Survey [Ref 30].

Data have also been used from oceanographic monitoring and sediment chemical analyses carried out during an EIA for the Sugozu Power Plant in July 1999 and October 2000 in the Gulf of Iskenderun. The power plant is located approximately 4-5km south west of the proposed BTC Marine Terminal site and oceanographic monitoring was undertaken approximately 1,000m offshore. Information from these studies is intended to supplement site-specific data and is considered indicative of the general conditions within the wider BTC Project area.

In addition to the environmental surveys and data sources listed above, social information, particularly on fishing activities, was obtained using the methods and approaches (questionnaires etc) outlined previously in Section 10.1 and detailed in Appendix A5.

11.1.3 Study area

The study area is defined as:

- for planned activities during construction and operation: the permanent and temporary footprint of the offshore components of the terminal (jetty and exclusion zone) and fishing communities involved in using the areas;

- for reasonably foreseeable accidental events during operation: the Gulf of Iskenderun, ie the zone of potential impact of an oil spill, which could occur with a reasonable probability as predicted in Section 14.

11.1.4 Section contents

The baseline information and relevant environmental characteristics of the marine environment in the BTC Marine Terminal study area are described under the following headings:

- Oceanography (currents, waves, tides, temperature, salinity and marine chemistry);
- Coastal and Seabed Characteristics (coastal morphology, sediments);
- Marine Ecology (plankton, benthos, fish, mammals, turtles, seabirds, intertidal habitats, protected areas and seasonal sensitivities);
- Marine archaeology;
- Human Activities (navigation and shipping, recreation and amenity, fishing).

11.2 OCEANOGRAPHY

11.2.1 Physical oceanography

11.2.1.1 General

The Gulf of Iskenderun is a mass of water in the north east of the Mediterranean Sea with an approximate area of 1,250km^2 and a volume of 95km^3, which may be considered a semi-enclosed area. The average depth is 70 to 80m, and the depth of the southern area where the bay is connected with the Mediterranean reaches 90m [Ref 1].

11.2.1.2 Currents

Surface currents within the eastern Mediterranean are generally weak with an anticlockwise gyre. The inshore current direction is variable and influenced by local wind patterns, whereby easterly currents dominate in summer and westerly currents occur in winter. Currents in the Gulf of Iskenderun lead to the formation of various micro-scale cells. These currents are caused by the wind and the extensions of the general current system of the Eastern Mediterranean entering the Gulf [Ref 2]. At the mouth of the Gulf, fluctuations caused by occasional variations in the current system and in the surface wind intensity can give rise to upwelling of the deepwater mass that enters the Gulf. Additionally, local upwelling of nutrient rich deep waters in the inner section of the Gulf may occur due to the clockwise rotating current cell [Ref 2].

Current measurements were taken, during the feasibility study for the proposed BTC Marine Terminal, at various locations and depths. Average surface currents in the Gulf of Iskenderun varied from 3.7 to 20cm s^{-1}. These currents were predominantly westerly, between 221 - 333º. Mid-water currents showed little variation in velocity of between 7.3 - 7.68cm s^{-1} and were from the southwest. Deeper currents, (at 20m), were shown to be highly variable from 6.78 to 41.09cms^{-1} indicating strong currents close to the seabed on occasion [Ref 3]. As with the shallower subsurface currents, these were from the southwest.

Modelling studies carried out during the feasibility study in order to determine the hydrodynamics of the Gulf of Iskenderun indicated that in summer, there is a clockwise gyre in the north and an anti-clockwise one in the south [Ref 3]. These give rise to currents flowing northeast along the coast near the proposed BTC Marine Terminal and southwest further offshore. The gyres (and consequently the direction of the currents) reverse in winter. These two vortices meet at the western coast of the Gulf, creating local disturbances.

Results of the survey undertaken for the Sugozu Power Plant indicate that the prevalent direction of current flow is from the southwest, however, during the autumn, the predominant current flows from the north easterly direction [Ref 4]. This is consistent with the seasonally reversing pattern predicted by the modelling studies carried out for the present work. Surface current flows were found to be higher during the winter period than compared with the rest of the year. Furthermore, the highest flow speeds were noted to be in the 200º and 40º directions, ie from the southwest and northeast.

11.2.1.3 Wave Patterns

The wave climate of the Gulf of Iskenderun was determined using wind data (both long term and extreme) from the two major meteorological stations in the region at Yumurtalik and Iskenderun. Near-shore characteristics were determined through wave transformation modelling, taking into account the effects of refraction and shoaling due to varying depths, local wind generation and energy dissipation due to bottom friction and wave breaking. Numerical model studies were carried out during the proposed BTC Marine Terminal Feasibility Study using two nested model areas (as design input to the proposed jetty) [Ref 3].

Wind generated waves arise at the entrance to the Gulf from the southwest. The island of Cyprus significantly reduces the fetch from the southwest and limits wave development. Results from hindcasting, which drew upon long-term wave statistics of the region, indicated that wave heights of the order of 3 – 4m occur every year and that waves from the southwest are predominant in the Gulf [Ref 3]. Results using extreme wave height statistics also indicate that wave heights greater than 3m occur almost annually at the entrance to the Gulf. From this analysis, wave heights of 4.15m (± 0.34m) - 5.10m (± 0.60m) are predicted for return periods of 10 - 50 years [Ref 3]. Hindcasting estimates suggest that the longest waves have periods of 7.7 - 8.5s with return periods of 10 - 50 years.

Near-shore wave characteristics (approximately 15m depth) at the proposed BTC Marine Terminal and Jetty location were determined through wave transformation studies of waves from deep waters. The studies showed that a wave height of 1.5m will be exceeded for 305 hours (5.4 days) in one year and that the most critical wave direction is SSW [Ref 3].

11.2.1.4 Tides

The maximum tidal range in the Gulf of Iskenderun is particularly low and estimated to be between 0.4 m and 0.6m [Ref 3]. However, fluctuations (unrelated to tides) of up to 1.5m are sometimes observed (probably related to meteorological factors), causing waters in the Gulf to recede and rise occasionally, giving rise to localised inundation [Ref 3]. During the proposed terminal feasibility studies, the maximum measured tidal range was 0.4m, which is consistent with previously observed tides.

11.2.1.5 Temperature

Winter water temperature within the Gulf of Iskenderun ranges between 13 - 15ºC and rises to between 27 and 29ºC in summer [Ref 5]. A thermocline develops in the Gulf between April and May, breaking down between November and February.

Seawater temperature measured near the proposed jetty location was relatively constant during winter from 17.4ºC at the surface to 17.6ºC at the seabed (25 – 40m depth) [Ref 3]. This is slightly higher than surface water temperatures previously recorded.

During spring, surface water temperatures varied from 20.5 - 20.9ºC, decreasing with depth to 19.6ºC close to the seabed [Ref 6]. A relatively weak seasonal thermocline was observed at 15m.

Surface water temperatures during the summer of between 27.7 - 28.2ºC were measured during the proposed terminal feasibility studies. A steep thermocline at approximately 5m was detected during the summer at the Sugozu Power Plant, below which changes in temperature were relatively small [Ref 6].

11.2.1.6 Salinity

Salinity throughout the wider area is fairly constant through the year at 39 parts per thousand (‰) [Ref 3]. Surface water salinity measured at the proposed jetty location varied from 37.9 - 39.3‰, fluctuating with season as well as with depth [Ref 6]. Both salinity and density were observed to increase with depth; this is possibly due to the influence of rainfall and freshwater drainage off the land. The most important freshwater input into the Gulf of Iskenderun is from the Ceyhan River (average output of $180m^3 s^{-1}$), particularly during April when the snow of the Taurus Mountains melts [Ref 3]. During spring, the sea surface salinity was slightly lower than winter values.

During winter, vertical profiles at the two stations sampled showed that the entire water column in this coastal region was well mixed due to the cooling and sinking of surface waters [Ref 3].

11.2.2 Marine Chemistry

11.2.2.1 Introduction

Chemical parameters were measured at two of the seven sampling stations during the winter season marine ecology survey carried out in February 2001, and at two of the eight stations during the spring season survey undertaken during May 2001. Additional data from the EIA for the Sugozu Power Plant have also been used as an information source. Although the survey was site-specific to the Sugozu Power Plant, the results provide an indication of the general water quality of the wider area. Sampling locations for all marine surveys undertaken in the vicinity of the proposed BTC Marine Terminal are marked on Figure 11.1.

The following parameters were measured during the winter season survey: salinity, temperature, dissolved oxygen, turbidity, dissolved inorganic nutrients (nitrate, phosphate and silicate), Total Suspended Solids (TSS) and total chlorophyll-a. These parameters, with the addition of pH, were also measured during the spring season survey. During the Sugozu Power Plant survey, ammonia concentrations were also measured and TSS and total chlorophyll-a were omitted. Data from these three studies are summarised in Table 11.1.

Table 11.1 Summary of Physical and Biochemical Parameters

Determinant	FEBRUARY (WINTER)		MAY (SPRING)		JULY (SUMMER)	
	Surface	Bottom	Surface	Bottom	Surface	Bottom
DO (mg l^{-1})	7.7	7.9	7.7	7.7	6.5	6.2
TSS (mg l^{-1})	4.7	7.6	8.3	11.9	-	-
chlorophyll-a (µg l^{-1})	0.1	0.4	0.3	0.1	-	-
PH	-	-	8.3	8.3	8.3	-
NO_3 (µg l^{-1})	806	50.2	3.7	44.0	18.6	17.2
PO_4 (µg l^{-1})	1.6	4.3	1.6	4.8	0.8	0.8
SiO_3 (µg l^{-1})	<76	<76	50.9	54.7	82.1	114

Source: [Ref 6]

11.2.2.2 General water quality parameters

Dissolved oxygen.

Winter and spring dissolved oxygen (DO) concentrations indicated that the water column was uniformly saturated with oxygen. Minor spatial variations in DO levels may be the result of local changes in photosynthesis, respiration, water temperature, salinity and surface film formation, which control the net accumulation and solubility of DO in the surface water as well as air-sea interactions [Ref 6].

Summer DO concentrations were slightly reduced, probably due to higher surface water temperatures experienced during summer as well as low numbers of phytoplankton. Surface waters were, nonetheless, close to saturated with oxygen down to 15m. However, the observed decrease in DO concentration from 6.45mg l^{-1} at the surface to 6.15mg l^{-1} in deeper waters is indicative of the presence of a thermocline/pycnocline in summer months, with photosynthesis largely confined to surface waters [Ref 5].

Small spatial variations in DO observed during marine surveys may have been due to biotic factors (photosynthesis and respiration) and/or abiotic factors (ie temperature, salinity, ocean-atmosphere interactions, mixing processes etc).

Suspended solids and transparency

Total Suspended Solids (TSS) concentrations measured during the winter survey increased by a relatively small amount with depth. However, spatial variations were evident with water column concentrations of between 3.8 - 4.8mg l^{-1} at the shallower station and 4.7 - 7.6mg l^{-1} at the deeper station [Ref 5]. Peak chlorophyll-a values of 0.36 µg l^{-1} were also observed near the seabed, concurrent with higher nitrate and phosphate concentrations. This suggests that much of the suspended material is algal cells (either phytoplankton or suspended epipelon[1]).

1 Epipelon is a term used to describe algae associated with the surface of the sediment.

Relatively small variations of TSS concentrations were observed during spring, ranging between 8.3 - 11.9mg l^{-1} [Ref 6]. The increase in TSS concentrations below the surface mixed layer is consistent with variations in chlorophyll-a levels. Chlorophyll-a concentrations were higher in the surface waters (0.26µg l^{-1}), decreasing to 0.11µg l^{-1} at 20m depth. This may simply be a function of light penetration into the water column.

pH

There was relatively little variation between pH values in the study area, ranging from 8.28 at the surface to 8.25 at the seabed, consistent with values for the northeast Mediterranean Sea. The relatively high pH suggests that algal production and respiration in surface waters within the study area is relatively low, with very little influence on surface water pH values [Ref 6].

Nutrients

Nutrient concentrations during both winter and spring surveys were relatively low. Nitrate (NO_3), phosphate (PO_4) and silicate (SiO_3) concentrations increased with depth, possibly as a function of reduced uptake by phytoplankton in deeper water [Ref 6].

Winter nitrate and phosphate concentrations varied between 50.2 – 806 µg l^{-1} and 1.6-4.3µg l^{-1} respectively. These relatively low concentrations and the low nitrate/phosphate ratio indicated that both nutrients may be limiting factors for algal production in the Gulf. Reactive silicate concentrations were <76µg l^{-1} throughout the water column, which is consistent with levels in the open Mediterranean Sea.

During spring, nitrate and phosphate levels in the water column and surface waters were low, with concentrations of 3.72µg l^{-1} and 1.6µg l^{-1} recorded respectively [Ref 6]. A slight increase of both phosphate and nitrate was recorded close to the seabed, probably due to a small influx from disturbance of the sediment layer. The low nitrate/phosphate ratio suggests that algal production in the surface waters of the Gulf may be limited by these nutrients. Silicate concentrations in the study area were also relatively low, suggesting that much of this is taken up by diatoms.

Again during summer, nutrient concentrations in the study area were low, similar to those in the open waters of the northeast Mediterranean, ranging from 0.8µg l^{-1} phosphate to <18.6µg l^{-1} nitrate. However, high concentrations of nutrients (8.7µg l^{-1} phosphate, 1,240µg l^{-1} nitrate and 988µg l^{-1} silicate) were found at the margin of the Gulf of Iskenderun, mainly due to freshwater inputs.

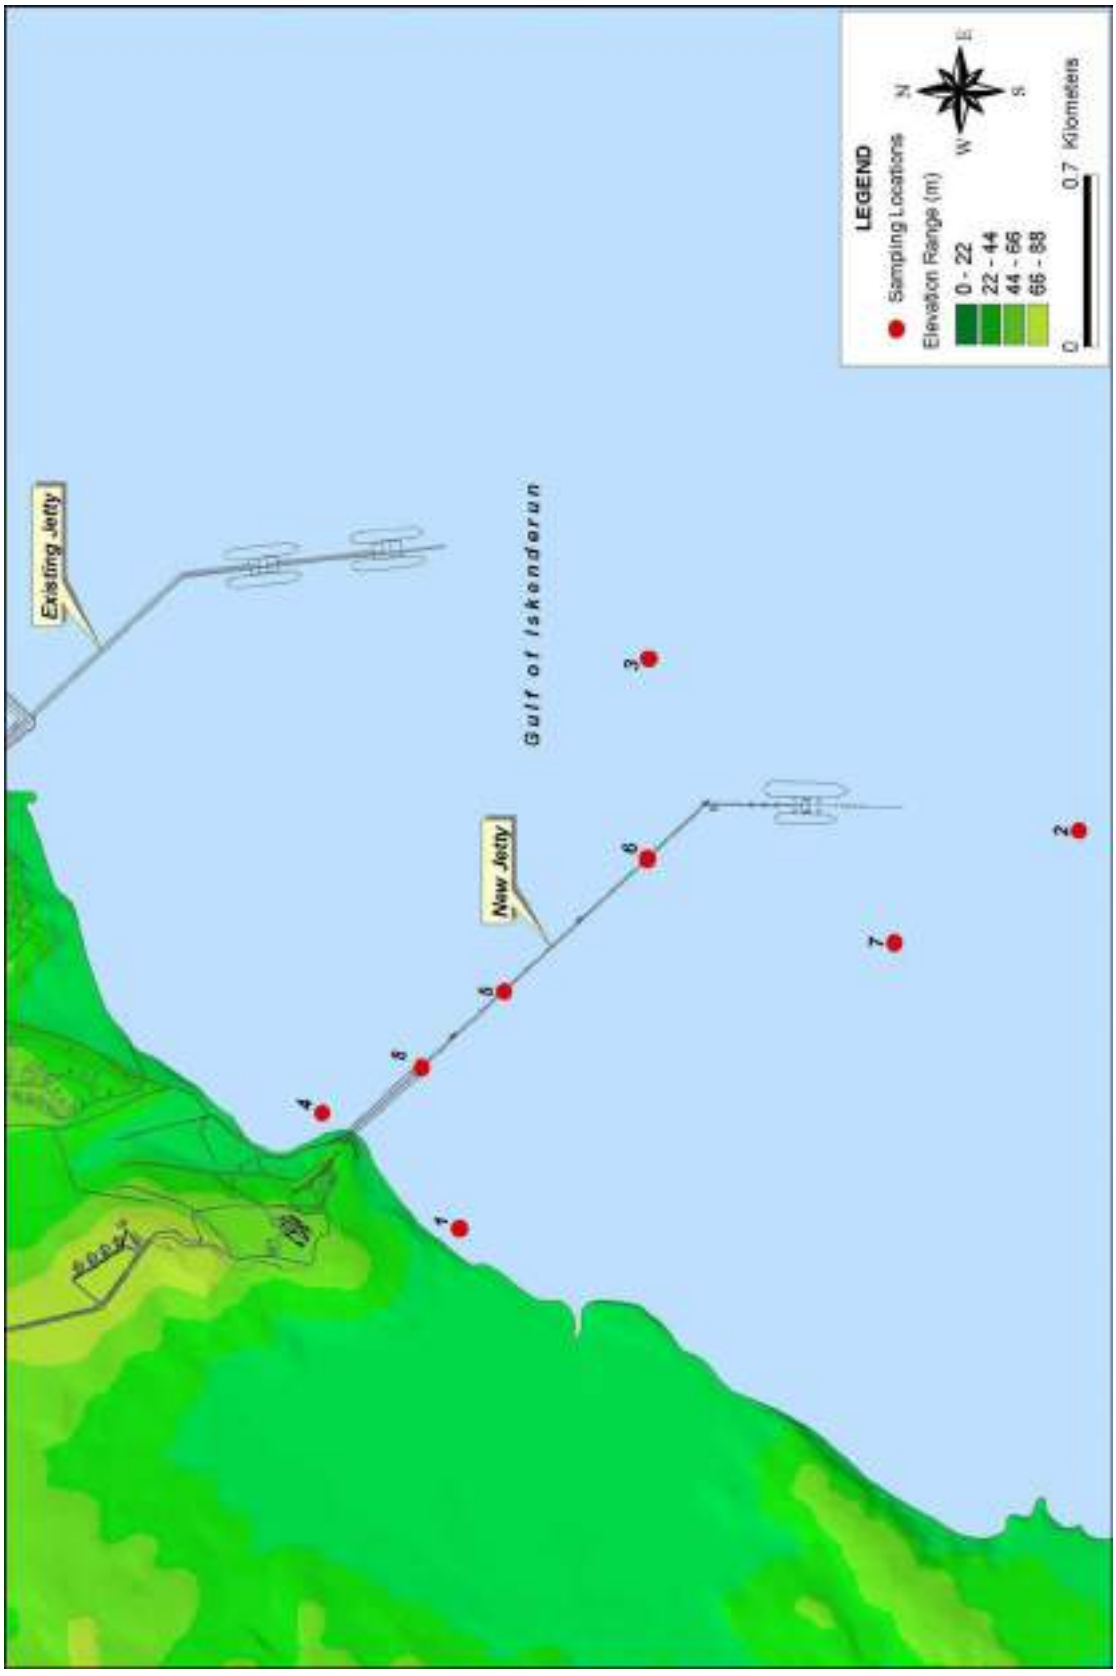

Figure 11.1 Marine Ecology Survey Sampling Locations (Winter and Spring 2001)

11.3 COASTAL AND SEABED CHARACTERISTICS

11.3.1 Beach morphology

The coast of Gulf of Iskenderun varies considerably, although it generally comprises level plains behind which lie the Taurus Mountains (see Figure 11.2).

The coast south west of the existing BOTAŞ Terminal, which encompasses the site of the proposed BTC Marine Terminal and Jetty, (and lies approximately 8km northeast of Yumurtalik), consists of undulating hills 120 – 180m high, interspersed with rocky and sandy bays. Beach widths along this stretch were estimated from aerial photographs taken in 2001 and appear to be relatively narrow, varying between 7 and 41m.

To the northeast, near the head of the Gulf, a sand and shingle beach borders a wetland stretching approximately from the Toros Gubre Fertilizer Facility site to the existing BOTAŞ Terminal.

11.3.2 Coastal processes

11.3.2.1 Coastal erosion

The Geohazard study for the proposed BTC Marine Terminal identified that the risk of coastal erosion is minor as the seabed is predominantly flat (approximately 1º slope). This suggests that net sediment transport will be relatively minimal [Ref 7]. Aerial photographs taken of the site in 2001 also suggest that there is no evidence of coastal retreat, however, beach morphology indicates a net northward transport of sediment.

11.3.2.2 Seabed stability

Direct examination of the seabed during the marine ecology surveys indicates that it is subject to movement under prevailing natural conditions from the shore down to 10 – 15m depth on the sandy bottom. This is indicated by ripples on the seabed [Ref 5]. The seabed becomes more stable with increasing depth and the transition from sand to silt. This is a reflection not only of hydrodynamic changes, but also of the more cohesive nature of the muddy deposits.

11.3.3 Bathymetry and seabed morphology

11.3.3.1 Bathymetry

The Gulf of Iskenderun is located on Turkey's south eastern Mediterranean coast in the region where the continental shelf is at its widest. The Gulf and the open sea adjacent to it are the most extensive shallow areas in the north eastern Mediterranean Sea. The average depth in the Gulf is between 70 – 80m and the bottom of the inner Gulf is extremely flat. The depth increases up to 90m in the southern section where the Gulf opens into the wider Mediterranean Sea. The seabed of the southern side of the Gulf generally slopes more steeply; the 50m isobath lies approximately 9km off the north shore and 4km off the south shore.

The shallow slope necessitates a long jetty at the BTC Marine Terminal, rather than a dredged approach to a quay.

Isobaths of the area surveyed during the proposed BTC Marine Terminal feasibility study are generally parallel to the coastline. A bathymetric map of the area is shown in Figure 11.3.

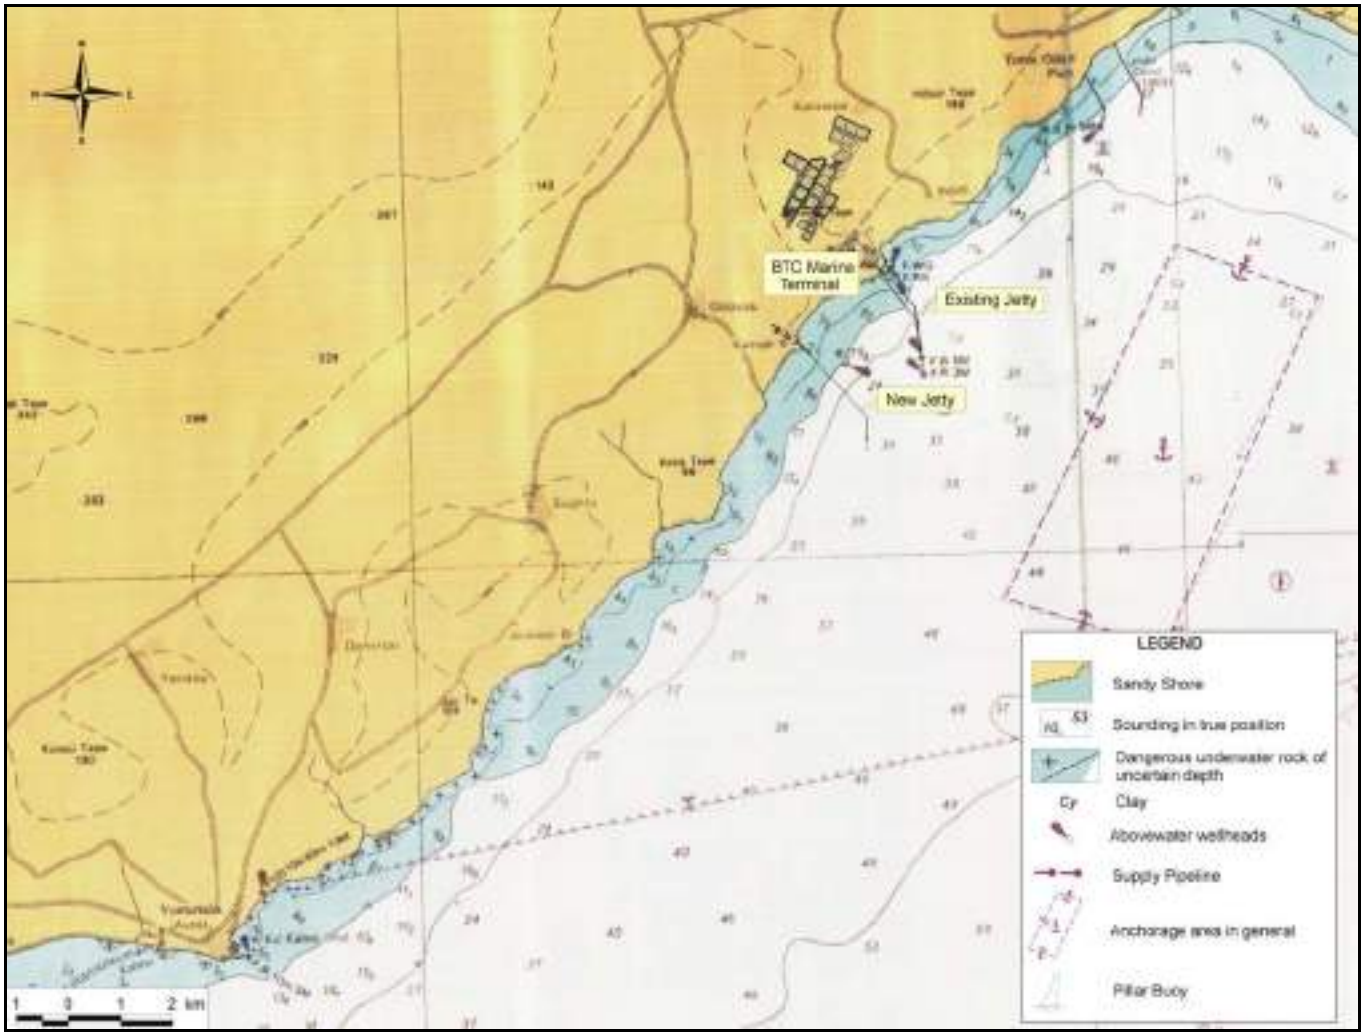

Figure 11.2 General Coastal Morphology

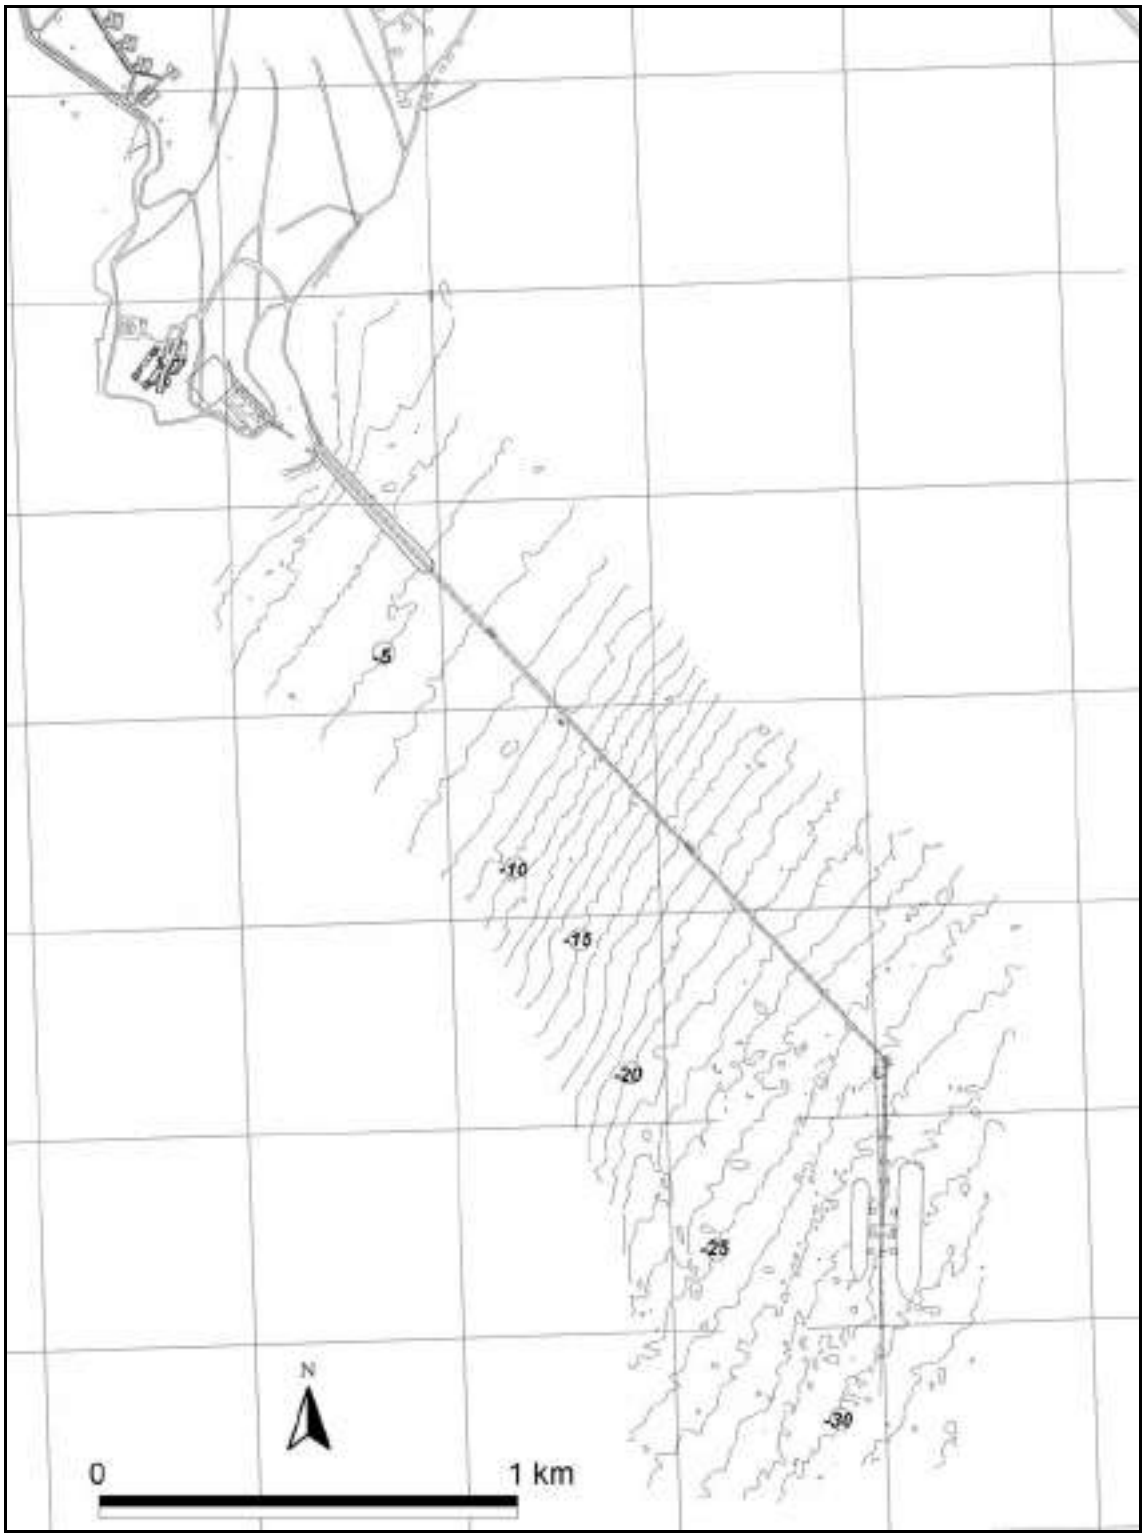

Figure 11.3 Bathymetry in the Vicinity of the Proposed Jetty

11.3.3.2 Seabed Substrates

Offshore boreholes drilled at water depths ranging from 21 - 44m and offshore seismic studies both confirm the presence of three main sediment layers beneath the seabed [Ref 8].

The profile of the seabed comprises marine alluvium overlying quaternary basalt, which in turn overlies Miocene flysch. The marine alluvium consists of clay and sand, with clay predominating. The clay unit is greenish grey, very soft, silty and of low plasticity, with a thickness of approximately 30m. Currently the sand unit is of medium density, silty and poorly graded, with a thickness of approximately 38m. Below this, the basalt unit appears to be a flat rock mass approximately 7m thick. The flysch unit extends into the sea and comprises alternating layers of sandstone, siltstone and claystone [Ref 8].

Sediment samples taken at 25 locations during the proposed BTC Marine Terminal Feasibility Study indicate that the surficial sediments comprise sand and silt in varying proportions, increasing in silt content with distance from shore (see Figure 11.4). The sediments appear to be lithogenous (ie derived from rock as opposed to sediments derived from biological processes), with silicaceous material being dominant.

The transition from sand to silty sand occurs at depths of 10 – 15m. At depths of >20m, a transition to a silt formation is apparent. This material is highly cohesive.

Grain size analysis of sediment samples taken during the Contamination Baseline Survey in February 2002 (see Table 11.2) indicates that the majority of the material is in the less than 150 µm size fraction comprising fine, very fine sand and silt.

Table 11.2 Grain Size Analysis of Sediments within the Area of the Proposed BTC Jetty

	Total Weight (g)	SIEVE SIZE			
		1.7mm	1.0mm	500µm	150µm
		Weight Retained in Sieve (g)			
Sieve 1	200	0.14 (0.07)	0.08 (0.04)	0.34 (0.17)	1.19 (0.60)
Sieve 2	138	- (-)	- (-)	0.04 (0.03)	1.42 (1.03)
Sieve 3	138	- (-)	- (-)	0.02 (0.01)	1.24 (0.90)
Sieve 4	146	- (-)	0.01 (0.05)	0.34 (0.23)	1.38 (0.95)
Sieve 5	150	- (-)	- (-)	- (-)	1.46 (0.95)
Sieve 6	200	0.09 (0.05)	0.07 (0.04)	0.35 (0.18)	3.69 (1.85)

11.3.3.3 Liquefaction

A geohazard study carried out at the BTC Marine Terminal site identified that although the risk of liquefaction in the vicinity of the new tank farm site is low, the potential for liquefaction to occur along the alignment of the proposed jetty will require investigation prior to the commencement of construction activities [Ref 7].

The sediment profile near the coast comprises a dense to medium sand layer over the bedrock, which is replaced by soft clay further away from the coast [Ref 8]. A subsequent study for the new jetty determined that there is no risk of liquefaction of soft clay and investigated the potential for liquefaction for the dense to medium dense sand layer. Soils with more than approximately 10% clay fines and a Liquid Limit of >32% are judged as unlikely to be susceptible to liquefaction [Ref **7**]. At the beginning of the new jetty alignment the value of fines in the ‘sand layer’ will be greater than 30% and it is expected that the material will not be susceptible to liquefaction (other than in the upper part of the sand layer) [Ref 7]. Furthermore,

this risk of liquefaction in the upper part of the sand layer will be manageable through design considerations such as reduced or no horizontal bedding. The study concludes that the risk of liquefaction along the alignment of the new jetty is minor due to the high content of fines and the high Liquid Limit in this area [Ref 8].

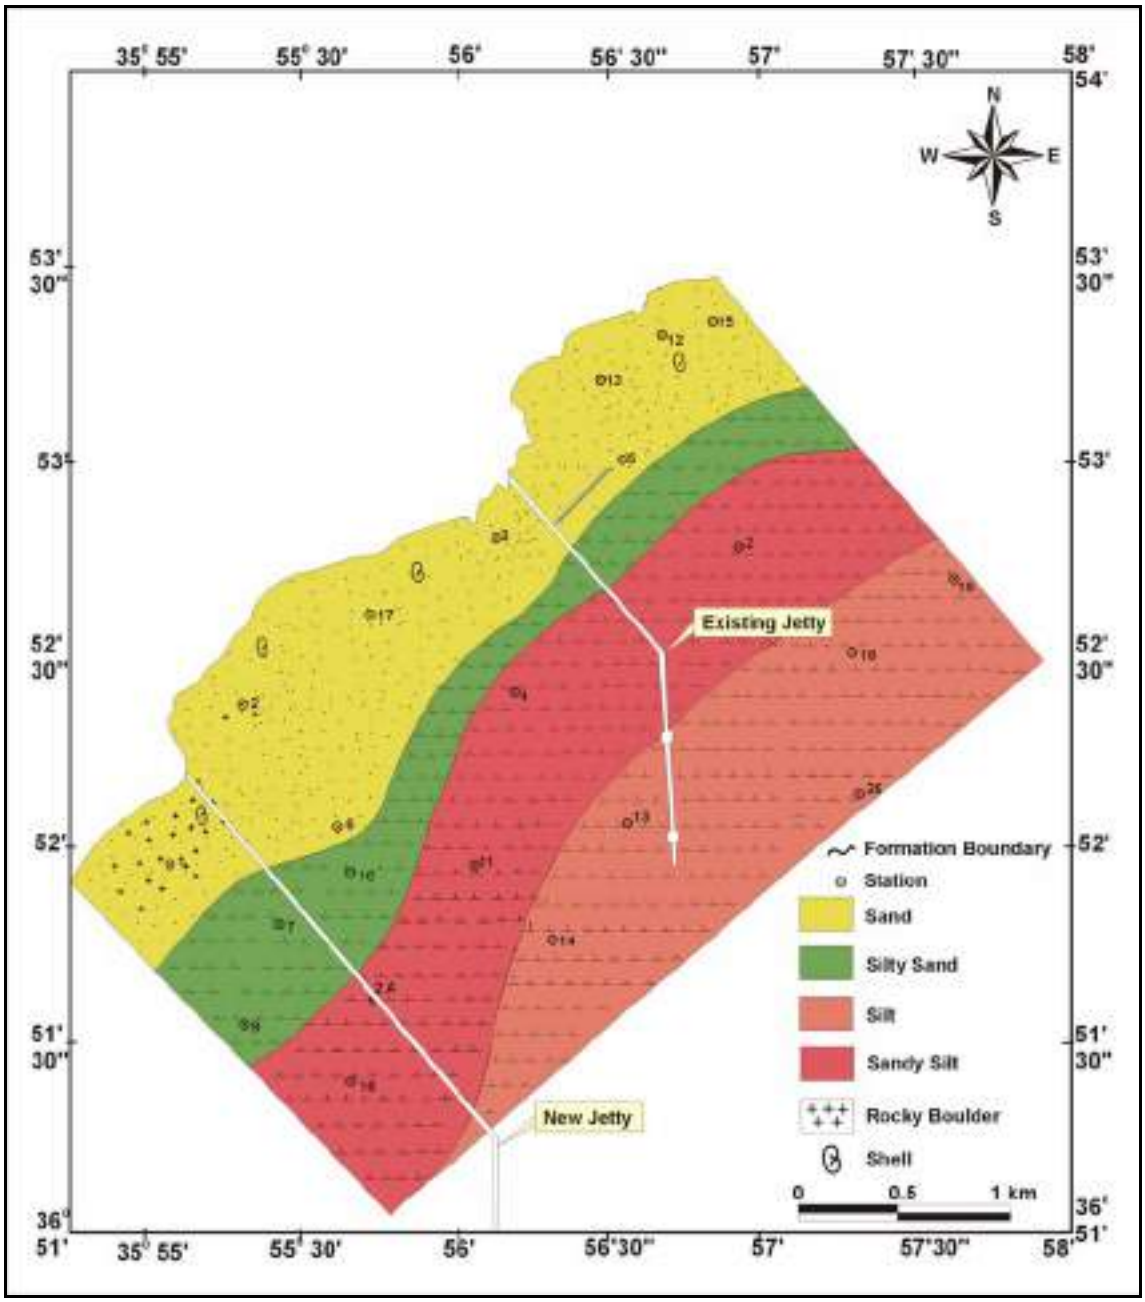

Figure 11.4 Sediment Distribution Map

11.3.4 Sediment quality

The Mediterranean is a semi-closed sea and exposed to pollution by virtue of it being surrounded by countries with high population densities and rapidly expanding industry.

Annual river and sewage canal discharge to the Mediterranean Sea is approximately 36.3 billion m^3 per annum, of which <1% of this is industrial wastewater discharge, containing toxic substances such as mercury, lead, chromium and zinc [Ref 9]. Agricultural activities constitute the largest source of pollutants via rivers and streams, with urbanisation, industrialisation, trade and tourism giving rise to increasing levels and varieties of pollutants.

The majority of terrigenous pollutants (ie those originating from terrestrial activities) entering the north-eastern Mediterranean originate from Turkey. Regional sea pollution has been particularly noted within the Gulf of Iskenderun and in the wider area along south west coast of Turkey, where a wide variety of manufacturing industries as well as mining activities and the hydrocarbons industry all contribute to marine pollution. Critical coastal and near-shore areas along Turkey's Mediterranean coastline include the Gulf of Iskenderun, as a result of its special hydrological features and an inflow of domestic and industrial wastewater [Ref 9].

11.3.4.1 Total Petroleum Hydrocarbons (TPH)

Previous studies have recorded the presence of high oil residues in areas such as the Gulf of Iskenderun. This has been attributed to the high levels of shipping. TPH biodegrades naturally in warm waters, hence any TPH found in sediments is likely to be derived from recent pollution events in the majority of circumstances, and in the absence of natural inputs (seeps, etc). It is likely that the numerous coastal industries (eg existing oil terminals at Ceyhan and Dortyol, the Toros Gubre Fertiliser Facility, Iskenderun steel works, etc) also contribute to the pollution load of the Gulf. The Gulf is therefore subject to high impacting pollution loads.

Sediment samples were taken during the Contamination Baseline Survey in February 2002 at seven different locations along the alignment of the proposed BTC Jetty (see Figure 11.5).

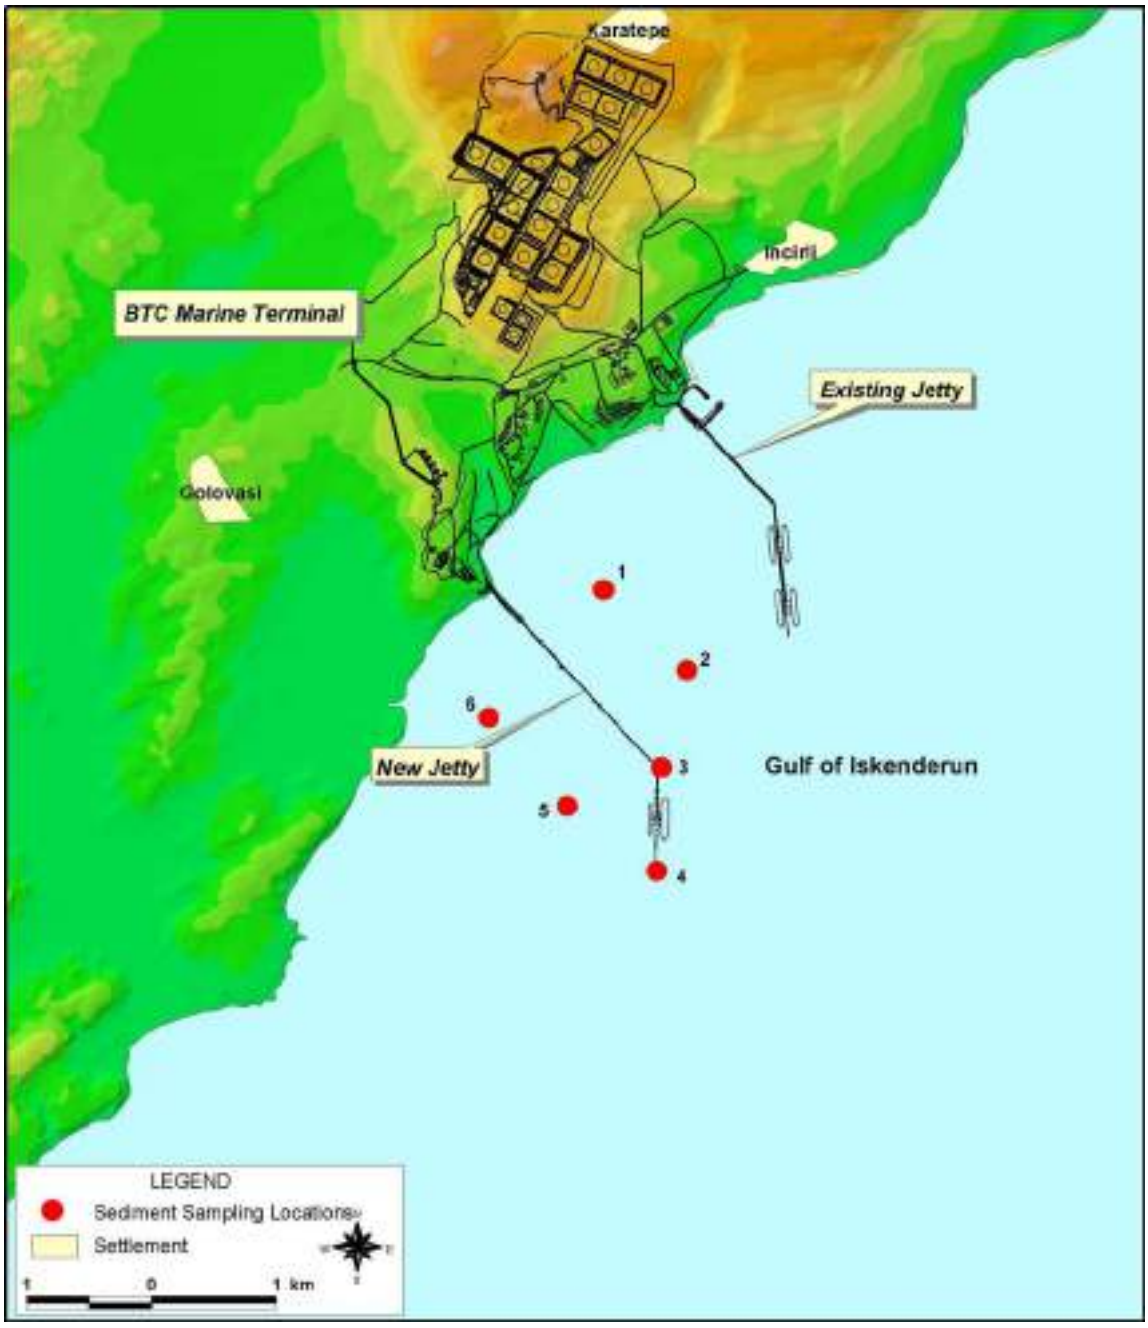

Figure 11.5 Locations of Sampling Sites for the Contamination Baseline and Winter Benthic Surveys, 2002

Table 11.3 shows TPH levels at each sampling site. The levels vary between less than 10 and nearly 100 mg/kg. Cairns reports that between these concentrations, TPH in sediments can begin to have an effect on biodiversity, so although not grossly polluted by any means there is some evidence of contamination [Ref 11]. However, the grain size analysis (see Section 11.3.3) also notes that sediment character varies from very fine sand to silt and back to very fine sand from sample 1 through to 6. The TPH levels observed indicate that contamination could be associated with finer material.

Table 11.3 Total Petroleum Hydrocarbon Analysis Results

11.3.4.2 Metal concentrations in sediment at the proposed jetty location

Heavy metals and persistent environmental contaminants tend to accumulate in soils and sediments. The main anthropogenic sources of heavy metals are:

1 the various industrial point sources around the Gulf of Iskenderun, such as present and former mining activities, foundries and smelters;

2 diffuse sources, including piping of products, combustion by-products, traffic etc.

The main heavy metals of concern in the Mediterranean Sea are cadmium (Cd), mercury (Hg), lead (Pb), chromium (Cr), copper (CU) and zinc (Zn).

Sediment samples were taken during February 2002 at six different locations along the alignment of the proposed BTC Jetty (see Figure 11.2).

Table 11.4 and Figure 11.4 give trace metal concentrations for mercury, aluminium, cadmium, copper, lead, tin and zinc and metal/aluminium ratios.

Table 11.4 Concentration of Trace Metals in Sediment Samples

	Lower Detection Limit (µg/g)	Sample 1 (µg/g)	Sample 2 (µg/g)	Sample 3 (µg/g)	Sample 4 (µg/g)	Sample 5 (µg/g)	Sample 6 (µg/g)
Mercury (Hg)	0.01	0.02	0.034	0.037	0.049	0.033	0.015
Aluminium (Al)	0.8	10400	23600	25000	26400	19000	10100
Cadmium (Cd)	0.05	0.1	0.16	0.18	0.14	0.13	0.09

Lead (Pb)	0.2	4.91	10.7	11.5	12.6	8.61	4.42
Tin (Sn)	0.3	1.5	1.4	1.6	1.6	1.5	1.8
Zinc (Zn)	0.06	25.3	61.2	64	67.2	46.6	24.1

Table 11.5 Metal/Aluminium Ratios in Sediment Samples

Metal/Al	Sample-1	Sample-2	Sample-3)	Sample-4	Sample-5	Sample-6
Hg/Al	$1.92x10^{-6}$	$1.44x10^{-6}$	$1.48x10^{-6}$	$1.86x10^{-6}$	$1.74x10^{-6}$	$1.49x10^{-6}$
Cd/Al	$9.62x10^{-6}$	$6.78x10^{-6}$	$7.20x10^{-6}$	$5.30x10^{-6}$	$6.84x10^{-6}$	$8.91x10^{-6}$
Cu/Al	$0.72x10^{-3}$	$1.11x10^{-3}$	$1.13x10^{-3}$	$1.11x10^{-3}$	$1.04x10^{-3}$	$0.69x10^{-3}$
Pb/Al	$4.75x10^{-4}$	$4.53x10^{-4}$	$4.60x10^{-4}$	$4.77x10^{-4}$	$4.53x10^{-4}$	$4.38x10^{-4}$
Sn/Al	$1.44x10^{-4}$	$0.59x10^{-4}$	$0.64x10^{-4}$	$0.61x10^{-4}$	$0.79x10^{-4}$	$1.78x10^{-4}$
Zn/Al	$2.43x10^{-3}$	$2.59x10^{-3}$	$2.56x10^{-3}$	$2.54x10^{-3}$	$2.45x10^{-3}$	$2.39x10^{-3}$

Aluminium is taken as a reference metal since it is naturally present in marine sediments in high concentrations and its concentrations is unlikely to be influenced by pollutant inputs. The ratio of measured metal to measured aluminium concentrations as shown in Table 11.5 can be compared to reference ratios. An order of magnitude difference between the ratios would indicate possible contamination.

Comparison of metal/aluminium ratios with OSPAR background ratios, (see Table 11.6), indicates that the sediments in the proposed BTC Marine Terminal area are slightly elevated above typical background concentrations with respect to copper (for some samples with fine material) and zinc [Ref 12].

Table 11.6 Background Metal/Aluminium Ratios Range in Fine Sediments or Fine Fraction of Sediments

Metal/Al	Range	Factor
Hg/Al	0.0034-0.0066	$*10^{-4}$
Cd/Al	0.007-0.03	$*10^{-4}$
Cu/Al	2.2-5.7	$*10^{-4}$
Pb/Al	1.8-4.0	$*10^{-4}$
Zn/Al	8.8-18	$*10^{-4}$

Note: The Range has to be multiplied with the Factor.

11.3.4.3 Metal concentrations in sediments in the area

The concentration of heavy metals within marine sediments was determined during a survey carried out for the Sugozu Power Plant using data representative of the wider project area. Sediments were sampled at 16 locations and analysed for zinc, lead, cadmium, nickel, vanadium, chromium, antimony and copper [Ref 13]. Comparisons of heavy metal concentrations in sediment samples have been made with published data.

- Cadmium concentrations were 0.36 ± 0.33 µg g^{-1} dry weight. In comparison with the typical range of values for cadmium in Mediterranean sediments (0.02 – 64 µg g^{-1} dry weight), this measured value is towards the lower end of the range.

- Lead concentrations were 63 ± 53 µg g^{-1} dry weight, which is at the lower end of the range found in Mediterranean sediments of 3 - 3,300 µg g^{-1} dry weight.

- The concentration of copper measured in the sediments of the Gulf was 37 ± 30 µg/g dry weight, which again is towards the lower end of the range for Mediterranean sediments (0.6 - 1,890 µg g^{-1} dry weight).

- The concentration of zinc within the sediments was measured as 126 ± 44 µg g^{-1} dry weight. This value is again within the range of typical Mediterranean sediments of 1.7 - 6,200 µg g^{-1} dry weight.

The metal concentrations measured in the Gulf of Iskenderun sediments are typical of those reported elsewhere. By comparison with reference values developed in the Netherlands (see Table 11.7), the concentrations of metals indicate no contamination. Although the sampled concentration for copper slightly exceeds the reference value, this concentration is typical of coastal areas, particularly those receiving run-off from land, and does not therefore indicate any significant contamination.

Table 11.7 Dutch Standards for Sediments (µg g^{-1})

Pollutant	Reference Value	Testing Value	Signalling Value
Cd	0.8	7.5	30
Cr	100	480	1000
Pb	85	530	1000
Hg	0.3	1.6	15
Cu	36	90	400
Ni	35	45	200
Zn	140	1000	2500

Explanatory notes:
Sediments containing metals in concentrations below the 'reference value' are considered uncontaminated, and are suitable for general disposal if present in dredged material at these concentrations.

Contaminant concentrations between the 'reference value' and the 'testing value' are considered moderately contaminated, and can be disposed of in open water under suitable conditions.

Sediments containing chemical concentrations between the testing value and the 'signalling value' are heavily contaminated, and can only be disposed of under controlled conditions.

If the 'signalling value' is exceeded, then the material is considered toxic waste, and is not suitable for marine disposal.

11.4 MARINE ECOLOGY

11.4.1 Plankton and pelagic systems

11.4.1.1 Phytoplankton

Marine ecology surveys identified a total of 53 species of phytoplankton during the winter season and 50 species during spring. In the winter surveys, 40 diatom, 11 dinoflagellate, one Chrysophyte and one Cyanophyte species were identified. Diatoms were present in almost all samples taken. During spring, 37 diatom and 12 dinoflagellate species were identified, with diatoms again the most abundant, comprising approximately 99% of the total phytoplankton [Ref 6].

The relative species composition and abundance of dominant groups for both winter and spring surveys were similar. Plate 11.1 illustrates plankton sampling techniques during the marine ecology surveys.

Plate 11.1 Plankton Sampling in the Gulf of Iskenderun

Results obtained during a summer survey near the Sugozu Power Plant identified that diatoms were also the most abundant algae at all sites. The algal species, *Leptocylindrus minimus*, *Leptocylindrus danicus* and *Chaetoceros* sp. were the most dominant species and present in all samples. Analysis based on the Bray-Curtis measure and multi-dimensional scaling showed that coastal samples differed significantly from those further offshore in terms of species composition and abundance.

This pattern is typical of temperate coastal areas.

11.4.1.2 Zooplankton

During both the winter and spring, marine ecology surveys, copepods were identified as the dominant and most abundant zooplankton, with *Oithona* sp. dominant at both sampling sites [Ref 6]. Copepods are generally widespread in distribution and dominate the zooplankton in many seas around the world, including the Mediterranean Sea.

The summer survey carried out at Sugozu Power Plant identified two dominant zooplankton groups; namely copepods and cladocerans. By contrast with copepods, cladocerans (water fleas) are less well represented in the sea, being a predominantly freshwater group. The genera *Evadne* and *Penilia* identified during these surveys, can nevertheless be an important component of the zooplankton in coastal waters, particularly in summer months.

11.4.2 Benthos

11.4.2.1 General

Benthos is a term used to describe organisms associated with the seabed. They comprise sessile and motile forms, as well as species living on the sediment (epibenthos) and animals living in the sediment (infauna). Only macrofaunal communities were surveyed as indicators of environmental quality and characterisation of benthic biotopes.

11.4.2.2 Epibenthos

Results from the marine ecology surveys showed that from 0.3 - 1.0m depth, a typical Mediterranean assemblage known as 'coralligène' is present, comprising mainly the red alga *Jania rubens*, barnacles and bivalves [Ref 6]. Epifauna observed within this assemblage included an abundance of fish species, including white seabream (*Diplodus sargus*) and common two-banded sea bream (*Diplodus vulgaris*), with few sponges (*Petrosia, Ircinia*) and anemones (*Cerianthus membranaceus*).

During spring and summer, high plant species diversity was noted, with algal species such as *Caulerpa prolifera, Codium* sp., *Dictyola cervicornis, Halopteris scoparia, Stypopodium schimperii* and *Padina pavonia* present [Ref 6]. The most abundant organism identified during visual surveys was the seaweed *Caulerpa prolifera*, which covered up to 45% of the seabed, decreasing during spring probably due to increased turbidity.

Below 10m, species diversity was low. Dredge samples taken at two depths of between 13–17m and 10m concurred with the dominant abundance of the green algae *Caulerpa prolifera* [Ref 6]. Other organisms identified included: seaweeds; fish, eg scald fish (*Arnoglosus laterna*); molluscs, eg the sea hare (*Aplysia depilans*) and *Strombus decorus*; crustaceans, eg the shrimp (*Alpheus glaber*) and the crab (*Thalamita poissonii*); and tunicates, eg *Phallosia mammillata*. The diversity of these groups increased during the spring survey.

The data suggest that the diversity of epibenthos within the immediate project area (ie the footprint of the proposed BTC Jetty and the associated exclusion zone) is low.

11.4.2.3 Benthic infauna

Infaunal organisms are divided into categories based on size. Macrofauna consists of those organisms that are >0.5mm in size; meiofauna are those within the size range of 0.5 - 0.062mm and microfauna are those organisms <0.062mm in size.

Results from grab samples taken during both the winter and spring marine ecology surveys identified a total of 51 macrofaunal species recorded during winter and 85 species during spring [Ref 6]. These comprised: molluscs; crustacea; polychaetes (bristle worms); one echinoderm and one nemertean (ribbon worm).

Species diversity varied between sampling locations, whereby deeper sites had higher species diversity than shallower ones. A seasonal variation between species identified was observed, with species such as the snail *Nassarius mutuabilisi*, the shrimp *Callinassa tyrrhena* and the worm *Glycera rouxi* found in winter and the shrimp *Allinassa subterrenea* and the worm *Megalone papillocornis* observed in spring [Ref 6].

No rare or protected species or assemblages were identified during the surveys.

Winter Benthic Survey 2002Sediment samples were taken during February 2002 at six different locations along the alignment of the proposed BTC Jetty (Figure 11.2). Triplicate samples were obtained at each sampling locations. Organisms were identified at the lowest taxonomic level possible. A computer program Multi Variate Statistical Package (MVSP) was used to provide an indication of species diversity although for a true statistical analysis a greater number of samples would be required.

The majority of species sampled were in larval form, which are very difficult to reliably identify. However, species were differentiated, thus allowing an assessment of diversity , and in turn an indication of the number of species present in the area. This therefore provided an indicator of habitat value and sensitivity at a level adequate for impact assessment. Organisms such as *Foraminifera* and *Radiolaria* are known to inhabit sandy bottoms and were observed at sampling sites 1 and 6. The greatest abundance of benthic organisms was found at sites 1 and 6. Polychaetes were observed in abundance at sampling sites 2 to 5, along with crustacea, gastropods, the decapod, *Crangon crangon* and the bivalve, *Tellina tenius*.

Table 11.8 shows typical species assemblages for sandy and silty communities. According to the Shannon-Weaver index, diversity of the sampled benthic population ranges from 0.5 to 2.158. Although a larger set of sampling data would provide greater statistical certainty, the data indicate a relatively high diversity of organisms. The lowest species diversity and number of species were observed at sampling sites 2 and 3, whilst the highest diversity and number were observed at sampling site 6. Hence, the trend in species diversity increases from a silty to sandy sediment composition.

Table 11.8 indicates the presence of two separate populations – one inhabiting sampling sites 1 and 6 (sandy sediment) and the second inhabiting sampling sites 2, 3, 4 and 5, which have a silty sediment composition. Conceivably the distribution could have other explanations, for example a correlation with the TPH levels measured during the survey in the same sediments (see Table 11.3). However, since gross pollution was not evident, the physical character of the sediment substrate is the most likely explanation for the observed distribution of benthos.

Table 11.8 Diversity Index and Sediment Composition at Sampling Sites

	Diversity Index	Number of Species	Sediment Structure (Visual Inspection)
1A	1.838	10	Very Fine Sandy
1B	1.849	10	Very Fine Sandy

6B	2.033	14	Very Fine Sandy
6C	2.125	14	Very Fine Sandy

11.4.3 Fish

A total of 650 fish species have been recorded in the Mediterranean Sea. Of these species, 90 species (representing 56 families) are relatively recent arrivals from distant seas. For the past 130 years, the main route of exotic fish species to the Mediterranean has been from the Red Sea through the Suez Canal (termed Lessepsian migration). The colonisation of Red Sea (Erythrean) fishes has had a major impact on Levantine waters where more than a dozen of these Lessepsian migrants have become important components of commercial fisheries (CIESM). Fish species (including Lessepsian fish species) present in Iskenderun Bay are identified below.

During the marine ecology surveys, *in situ* visual observations, bottom trawls and midwater trawls were undertaken to identify key fish species in the vicinity of the proposed BTC Jetty. The visual investigation undertaken during the winter survey identified a dense accumulation of fish at 7 m depth within an area of scattered stones and rocks. The giltheads *Diplodus sargus, Diplodus vulgaris* and the pandora *Pagellus erythrinus* were the most abundant species.

Trawl surveys revealed an abundance of five fish species during the winter survey; brushtail lizardfish (*Saurida undosquamis*) red mullet (*Mullus barbatus*), barracuda (*Sphyraena sphyraena*), pandora (*Pagellus erthrynus*) and the sennet (*Sphyraena chrysotaenia*), which are all noted for their high commercial value. The lizardfish and sennet are both Lessepsian migrants.

The species composition in spring shifted to the near absence of commercially important fish. The most common fish in spring were the rainbow sardine (*Dussumeria elopsoides*) (identified as *D.acuta*; another Lessepsian migrant), brushtail lizardfish, annular bream (*Diplodus annularis*), golden grey mullet (*Liza aurata*) and striped mullet (*Mugil cephalus*) [Ref 6]. However, catch per unit effort (CPUE)[1] increased during the spring from 8–20kg, indicating an overall increase in total fish abundance. Furthermore, during both the winter and spring surveys, a significant concentration of fish larvae were caught both during day and night trawls, comprising species such as bass (*Dicentrachus labrax*), the goby (*Oxyurichthys petersi*) and barracuda or sennets (*Sphyraena* sp) [Ref 6]. This indicates the potential presence of nursery grounds for these species within the Gulf of Iskenderun.

Data from the Sugozu Power Plant marine ecological survey carried out during the summer also provide an indication of the fish species found in the vicinity of the proposed BTC Jetty and its exclusion zone. The major species caught during trawl surveys was the silverbelly (*Leiognathus klunzingeri*), which is a Lessepsian migrant. Although this species is not important economically, it is an important prey item for larger piscivorous fish. Additionally, the commercially important red mullet and pandora were also caught during trawls, although their average size was very small, suggesting that this area is a nursery ground for these species. Of particular note was the disappearance of the previously dominant brushtail lizardfish indicating the over exploitation of this fish within the Gulf of Iskenderun.

Fisheries and important fishing grounds are discussed in Section 11.6.5 and shown on Figure 11.9.

[1] CPUE is used as a relative measure of fish "catchability", both in commercial fishery assessments and when comparing data from surveys collected using different methods.

11.4.4 Marine Mammals

11.4.4.1 Mediterranean Monk Seal

The Mediterranean monk seal (*Monachus monachus*) is the only seal occurring in the Mediterranean Sea and is described as 'critically endangered' in the IUCN Red List of Threatened Species [Ref 14]. The monk seal is protected under Appendix I of CITES, Appendix II of the Bonn Convention, Appendix II of the Berne Convention and Annex II and IV of the EU Habitats Directive. Although the EU Directive does not apply in Turkey, the monk seal is protected by Turkish national legislation under Article 2 of the Terrestrial Hunting Law (dated 05.05.1937, number 3167), which is updated annually by the Central Hunting Commission. The monk seal is currently protected for the 2001/2002 hunting season.

The monk seal has a world population of less than 400-500 individuals divided into two populations – the Mediterranean Population (Greece, Turkey and the East Mediterranean) and the Atlantic Population (Mauritanian Islands, Madeira Islands and Morocco). The Aegean Sea and the area between the south coast of Turkey and the north coast of Cyprus are the most important for this species. Research indicates that the previously recorded Black Sea monk seal is now extinct [Ref 25].

It is estimated that at least 50 monk seals presently live on the shores of Turkey. The primary habitat type is remote and undeveloped rocky shores and caves. Monk seals are diurnal mammals, live in groups of up to 20 individuals, occupy a limited home range and do not migrate. The reproductive period is mainly between May and November. Mating usually occurs between October and November with females giving birth after an 11-month gestation period.

The presence of monk seals has been recorded along much of the Mediterranean coast of Turkey to the Syrian Border, with the exception of the coastline from Mersin to Iskenderun. Interviews with local fishermen in the Gulf indicate that monk seals have been seen along the coast at Yumurtalik and Sugozu (Mustafa Sen, *pers. comm.*). Additional available data suggest that the seal population in the Gulf of Iskenderun is restricted to the south coast and that it is unlikely that seals are present in the vicinity of the proposed BTC Marine Terminal. It is probable that the existing level of disturbance due to industrial activity along the north coast of the Gulf renders this area unattractive to seals [Ref 15, Ref 16].

11.4.4.2 Cetaceans

Information on the distribution of cetacean species in the eastern Mediterranean Sea is patchy, however, many species have been recorded in the Mediterranean as a whole. Table 11.9 identifies cetacean species recorded off the south coast of Turkey. Although there are no specific records relating to sightings of cetaceans in the Gulf of Iskenderun, cetaceans may stray into the Gulf on occasion. More detailed information on each species recorded may be found in the Mammal Species Dossier (Appendix B1).

Table 11.9 Cetacean Species off the South Turkish Coast

NAME	DISTRIBUTION IN TURKEY	STATUS IN INTERNATIONAL LEGISLATION	STATUS IN TURKISH LEGISLATION
Bottlenose dolphin *Tursiops truncates*	Widespread in Turkish waters	Data Deficient – IUCN Red List 2000. Appendix II of CITES; Appendix II of Bonn and Bern Conventions; Annex II and IV of EU Habitats Directive	Protected
Common dolphin *Delphinus delphis*	Population believed to be declining sharply	Not globally threatened Appendix II of CITES; Appendix II of Bonn and Bern Conventions; Annex IV of EU Habitats Directive	Protected
Risso's dolphin *Grampus griseus*	Population believed to be declining sharply	Data Deficient – IUCN Red List 2000.Appendix II of Bonn and Bern Conventions; Annex IV of EU Habitats Directive	Protected
White beaked dolphin *Lagenorhynchus albirostris*	Rare in Turkish waters	Data Deficient – IUCN Red List 2000.Appendix II of CITES; Appendix II of Bonn and Bern Conventions; Annex IV of EU Habitats Directive	Protected
Harbour porpoise *Phocoena phocoena*	Currently under risk of extinction in Turkish coastal waters	Vulnerable – IUCN Red List 2000. Appendix II of CITES; Appendix II of Bonn and Bern Conventions; Annex II and IV of EU Habitats Directive	Protected
Sperm whale *Physeter macrocephalus*	Rare in Turkish waters	Vulnerable – IUCN Red List 2000. Appendix II of CITES; Appendix II of Bern Convention; Annex IV of EU Habitats Directive	Protected
Note: Turkey is a signatory to the Bern Convention, although no specific protective provisions have been introduced in law.

11.4.5 Turtles

11.4.5.1 General

Of the seven oceanic turtle species, two are known to breed in the Mediterranean: the Loggerhead (*Caretta caretta)* and the Green turtle (*Chelonia mydas*). Although the Leatherback (*Dermochelys coriacea*) regularly occurs in small numbers, the species does not nest in the Mediterranean. The Nile Soft-shelled turtle (*Trionyx triunguis*) also occurs in the Mediterranean

Sea, with the main populations in Turkey and Israel. All marine turtles are classified globally as threatened species and are protected by most Mediterranean countries; the status of the four turtle species found in Turkish waters is summarised in Table 11.10 below [Ref 19].

Table 11.10 Turtle Species off the South Turkish Coast

NAME	DISTRIBUTION IN TURKEY	STATUS IN INTERNATIONAL LEGISLATION	STATUS IN TURKISH LEGISLATION
Green Turtle *Chelonia mydas*	Widespread in Turkish waters	Mediterranean population is Critically Endangered (CR) on IUCN Red List 2000. Appendix II of the Bern Convention and Appendix I of the Bonn Convention. Annex II and IV of the EU Habitats Directive	Protected
Loggerhead Turtle *Caretta caretta*	Most common turtle in Mediterranean waters	Endangered (EN) on the IUCN 2000 Red List Appendix II of the Bern Convention and Appendix I of the Bonn Convention Annex IV of the EU Habitats Directive	Protected
Nile Soft–shelled Turtle *Trionyx triunguis*	Total population is not believed to exceed 500 adults in Mediterranean waters.	Mediterranean population is Critically Endangered (CR) on the IUCN 2000 Red List Appendix II of the Bern Convention	Protected
Leatherback Turtle *Dermochelys coriacea*	Population believed to be widespread across the worlds major oceans	Critically Endangered (CR) on the IUCN 2000 Red List Appendix II of the Bern Convention and Appendix I of the Bonn Convention Appendix I of CITES Annex IV of the EU Habitats Directive	Protected
Note: Turkey is a signatory to the Bern Convention, although no specific protective provisions have been introduced in law.			

Source: IUCN 2000 Red List; Appendices& Annexes to Bern & Bonn Conventions and relevant EU Directives.

11.4.5.2 Green Turtle (*Chelonia mydas*)

Green turtles are rare in temperate waters, but are distributed widely through the tropics near continental coasts and around islands. There are important nesting and feeding grounds around the whole coast of Africa, India and South East Asia and along the entire coastline of Australia. They are found in the Mediterranean Sea and occasionally as far north as the coastal waters of

Great Britain. The Mediterranean population is regarded as Critically Endangered on the IUCN 2000 Red List.

Sea turtle numbers are almost impossible to estimate because of their migratory lifestyle. Estimates of numbers of nesting females are possible but data are not available from all beaches and numbers may be confused due to the uncertainty of how many times an individual nests in a season.

11.4.5.3 Loggerhead Turtle (*Caretta caretta*)

Loggerheads are widely distributed in coastal waters, mainly in subtropical and temperate regions. Nesting beaches are distributed in more temperate latitudes than those of other sea turtles. Loggerheads are the most common turtle in the Mediterranean, with nesting reported along many coastal beaches, notably in Greece, Turkey, Cyprus and Libya. The species is categorised as Endangered on the IUCN 2000 Red List (see Plate 11.2).

Worldwide numbers are almost impossible to calculate because of the wide range of these migratory animals. It is possible to estimate numbers of adult females on nesting beaches, however not all of these sites have been surveyed, and numbers may be confused due to uncertainty about how many times a female nests in a season [Ref 18].

Plate 11.2 Loggerhead Turtle

11.4.5.4 Nile Soft-shelled Turtle (*Trionyx triunguis*)

The Nile Soft-shelled turtle is distributed throughout the eastern Mediterranean, although it has been estimated that the total Mediterranean population does not exceed 500 adults. The main populations are found in Turkey and Israel, with a few smaller populations in Egypt, the Lebanon and Syria. The species is protected under Appendix II of the "Convention on the Conservation of European Wildlife and Natural Habitats" and has Critically Endangered status on the IUCN 2000 Red List [Ref 20].

11.4.5.5 Leatherback Turtle (*Dermochelys coriacea*)

The Leatherback turtle is a wide-ranging species with individuals being tracked across the world's major oceans. It has been described as having a temperate range with tropical nesting habits indicating its wide distribution range. It is thus found in the Atlantic, Pacific and Indian

Oceans, as well as being recorded from within the Mediterranean. It has Critically Endangered status on the IUCN 2000 Red List.

11.4.5.6 Turtle species within the vicinity of the Gulf of Iskenderun

The coast between the Turkish border with Syria and the Goksu Delta has been previously studied for evidence of sea turtle activity and four important nesting beaches were recorded – the Goksu Delta, Kazanli, Akyatan and Samandag (see Figure 11.6). It has been estimated that this area accounts for over 70% of the Green Turtle nesting sites in the entire Mediterranean region; this equates to less than 500 nest sites.

These sites are all outside of the Gulf of Iskenderun, but might be at risk from a major oil spill (see Section 14).

The Loggerhead turtle is one of the most widely distributed and numerous turtle species in the Mediterranean, with an estimated 2000 nesting females. However, the status of the species remains critical and it is classified as an endangered species on the IUCN 2000 Red List. Unlike Green turtles, however, the Mersin Bay and Gulf of Iskenderun coasts have a secondary importance as nesting sites for this species.

The Nile Soft-shelled turtle is thought to number as few as 500 adults throughout the entire Mediterranean basin although information about distribution is scarce. The Turkish population represents a globally significant resource, most of which is concentrated in the Cukurova delta. The Goksu River, Kazanli, Seyhan River, Adana-Akyatan, Gulf of Iskenderun and Asi River represent important habitats for this species.

The Leatherback turtle is a sporadic visitor to the coastal area between Mersin Bay and the Gulf of Iskenderun.

Generally, nesting activity amongst each of the sea turtles species starts in early June and lasts until late August, with a peak around mid-July, although Loggerhead turtles start nesting slightly earlier than the Green turtle. Depending on the species and temperature, hatching takes from 40 to 60 days after the eggs are laid and, therefore, the hatching season ranges from July to September [Ref 21, Ref 22].

11.4.5.7 Turtle species in the vicinity of the Marine Terminal

During July 2001, a preliminary sea turtle survey was carried out for the proposed BTC Marine Terminal along the coastline between the Hurma Strait to the west and Dortyol to the east of the proposed terminal (see Figure 11.7). The study area is believed to include the major over-wintering location for Green turtles in the Mediterranean Sea and may therefore be an important area for sea turtles all year round (see attached case study).

High levels of turtle activity (including nesting) were observed over approximately 20% of the study area in the areas of Uzunkelli to Golovasi/Sahil Sitesi, the existing BOTAŞ facilities (Section No. 10 on Figure 11.7.) and the short area of beach between Kaplan Creek and the BOTAŞ Dortyol oil terminal (see Figure 11.7). The survey indicated the presence of two nests on the small beaches within the boundaries of the existing BOTAŞ Terminal facilities. Turtles were less evident in the areas between Hurma and the Ceyhan Strait and the Liman Cape to Yumurtalik.

However, the coastline in the immediate vicinity of the proposed BTC Marine Terminal is considered as unsuitable nesting grounds for the only two species of marine turtle observed

during the survey, the Loggerhead turtle and Green turtle due to the rocky coastline and lack of suitable sheltered sandy beaches. Table 11.11 gives distances from surveyed sections where turtle activity (including sightings of live/dead turtles, nests and tracks) was observed to the new jetty location.

Table 11.11 Distances of Observed Turtle Activity to the Proposed BTC Jetty

Section Number*	Average Distance from New Jetty (km)
1	40
2	30
5	18
7	7
8	2.6
10	3
13	18

A substantial number of dead turtles were recorded during the survey and is indicative of the level of pressure already experienced by these species within the Gulf of Iskenderun area. Discussions with members of the local communities suggest that numerous turtles are drowned every year in fishing nets, as well as being deliberately killed by fishermen who consider them a threat to fish traps.

In light of the findings of the July 2001 survey, a month long survey was conducted in the area between Sugozu and Uzunkelli within an area in which turtle nesting and hatching had been previously reported [Ref: 23]. Undertaken between early July and early August (a key period of nesting/hatching activity), the survey comprised routine nesting patrols and hatchling observations on Sugozu and Akkum beaches, which had been identified during pre-survey field investigations as being key nesting sites (see Figure 11.7). The results of the survey are presented in Table 11.12 below.

Table 11.12 Nest and Track Data (Between 08.07.2002 and 08.08.2002)

	Nests		Non-nesting emergences	
Sugozu:	*Chelonia mydas*	*Caretta caretta*	*Chelonia mydas*	*Caretta caretta*
Directly observed:	9	6		
Recorded by tracks:	19	10		
Sugozu Total:	28	16	7	4
Akkum:				
Directly observed:	2	0		
Recorded by tracks:	12	2		
Akkum Total:	14	2	13	2
TOTAL	70	34	20	6

In should be noted that the survey was undertaken in the middle of the peak period and that the survey results do not reflect the complete nesting activity for this season. It is estimated that for the complete nesting period, the number of nests would be at least two times more than those observed in this survey.

On Sugozu Beach, it was observed that the eggs and hatchlings were heavily predated by crabs (*Ocypode cu*rsor) and the intensive predation is considered to significantly affect the number of hatchlings reaching the sea.

On Akkum Beach, eggs and hatchlings were also predated by foxes (*Vulpes vulpes*), with a total of six raided nests encountered during morning patrols. As at Sugozu Beach, high crab (*Ocypode cursor*) predation was also observed and contributed to a level of overall predation pressure that resulted in the low numbers of hatchlings reaching the sea.

The Action Plan for the Conservation of Mediterranean Marine Turtles, adopted in 1989, sets out a number of recommended actions to be taken at a national level within Turkey. Particular attention is required regarding the Green turtle and the legal protection of its nesting sites.

The Gulf of Iskenderun is specified within the Action Plan as requiring measures for the reduction of fishery-related mortality in the turtles' benthic feeding grounds [Ref 24]. High sea temperatures all year round and strong nutrient inputs from land increase primary productivity within the Gulf, providing one of the few locations in the Mediterranean used by Green turtles to nest, feed and overwinter.

The findings of the surveys undertaken as part of the BTC Pipeline EIA process indicate that the reproduction success of Green and Loggerhead Turtles is significantly affected by high levels of egg and hatchling predation and that locationally specific conservation measures may be required to protect turtle nests and to maximise the numbers of hatchlings reaching the sea.

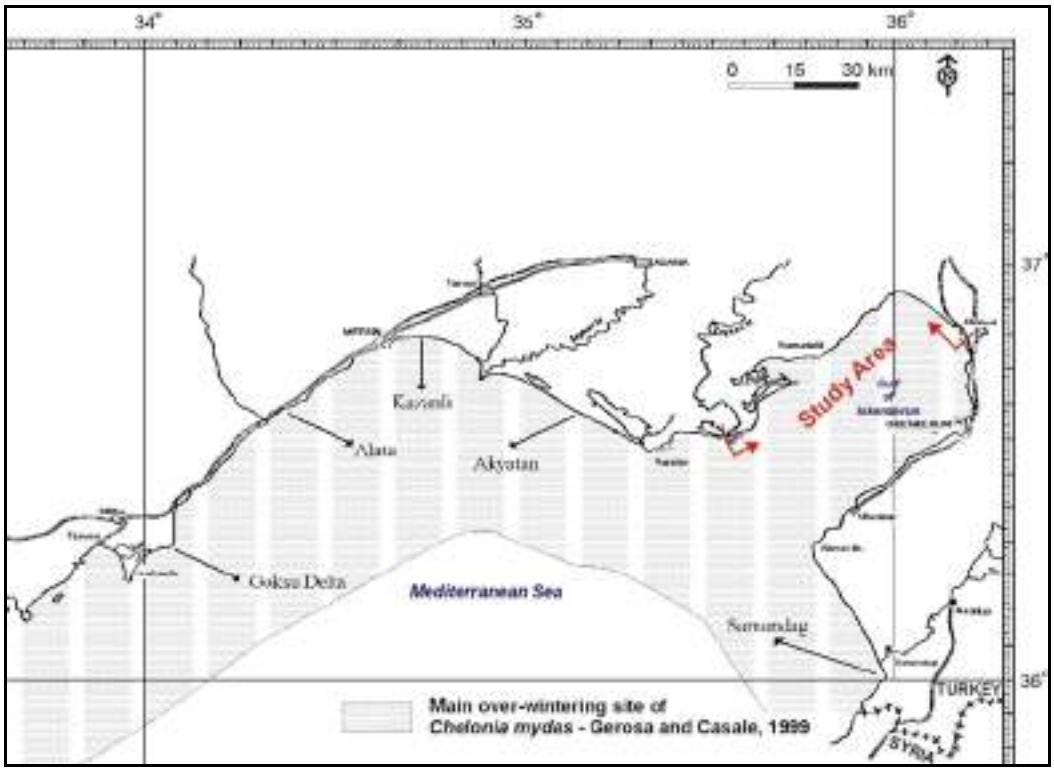

Figure 11.6 Map of Known Turtle Nesting Beaches

2002
BTC MARINE TERMINAL SEA TURTLE STUDY
The BTC Marine Terminal is located within the Gulf of Iskenderun, an area within which four turtle species have been recorded of which two are known to nest.
- Green Turtle (Chelonia mydas) is listed as Critically Endangered on the 2000 IUCN Red List of Threatened Species and it is estimated that only 300 to 400 Chelonia mydas females nest annually in the Mediterranean. Green Turtles nest in the Gulf of Iskenderun, where they are considered the most numerous of the turtle species.
- Loggerhead Turtle (Caretta caretta) is listed as Endangered in the 2000 IUCN Red List of Threatened Species and, although this is the most abundant species in the Mediterranean, the Gulf of Iskenderun has a secondary importance for the nesting of this species.
During July 2001, a preliminary sea turtle survey established that, although the coastline in the immediate vicinity of the BTC Marine Terminal was unsuitable for turtle nesting, two important nesting beaches, Sugoru and Akkum are located approximately 2km and 4 km west of the proposed jetty respectively. In addition, two nest sites were identified on the small beach within the existing Ceyhan Marine Terminal.
In July-August 2002, a detailed follow-up survey was undertaken to establish the level of nesting activity and the critical pressures that influenced hatching success, with a view to developing proactive measures that might safeguard turtle nesting in the area.
Sugoru Beach
Akkum Beach
Turtle Conservation Measures:
The BTC Project has committed to implement an Environmental Investment Programme (EIP). Measures to protect and preserve turtle nesting activity and to maximise hatching viability in the vicinity of the existing and proposed Marine Terminals are currently being considered. Within the provisions of the Action Plan for the Conservation of Mediterranean Marine Turtles (endorsed by each of the Mediterranean Coastal States under the Barcelona Convention), the measures to safeguard turtle nesting on the SOTAS beach and on the nearby beaches, including the collection of laid eggs for transferral to a protected hatchery area, in-situ protection and the management of releasing hatchlings.
Survey Findings:
Turtles of the gulf of Iskenderun nest between June - August, with hatching emergence from mid-late July to mid September. The surveyed beaches are heavily used by nesting females of both species with an estimated minimum of 250 nestings occurring within one season. However, hatchlings and eggs on the surveyed beaches are heavily predated by foxes and crabs, such that relatively small numbers of hatchlings reach the sea.
btc

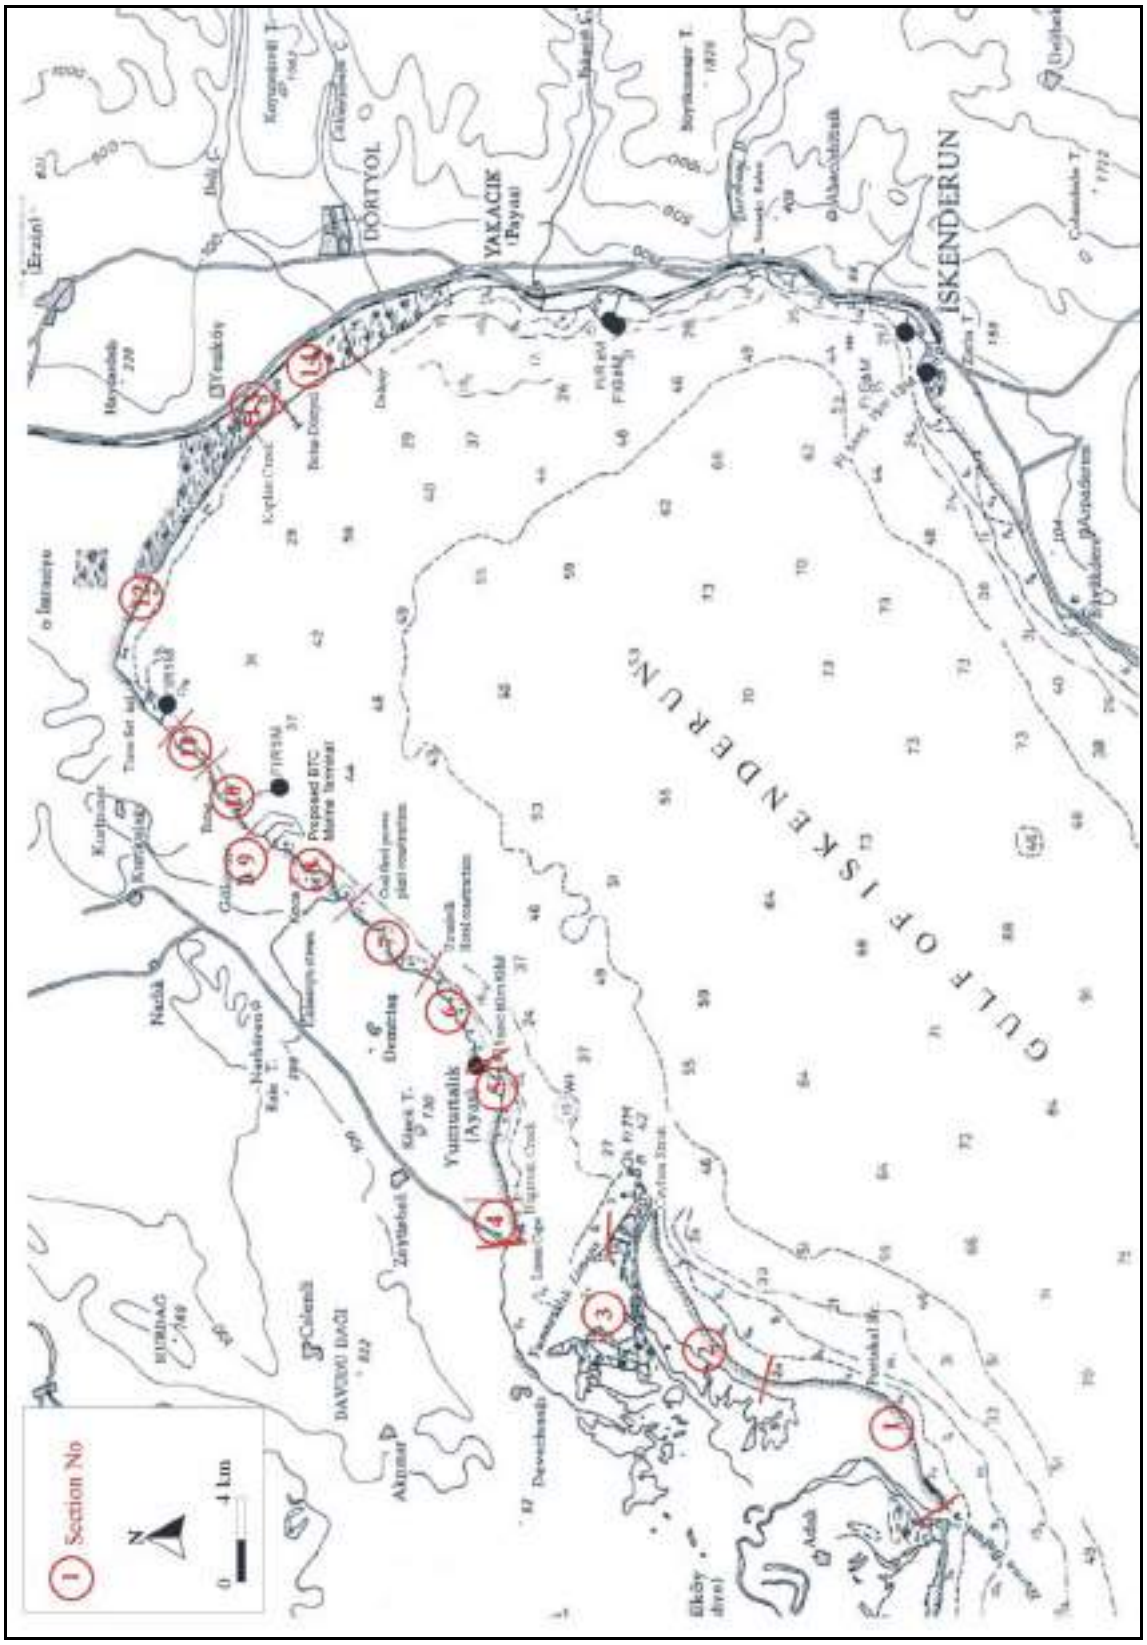

Figure 11.7 Turtle Survey Sites

Figure 11.8 Sites of the 2002 Turtle Survey

11.4.6 Seabirds

11.4.6.1 General

Both the population sizes and diversity of seabirds are relatively low in the Mediterranean, partly because of the low biological productivity and nutrient scarcity. Upwellings, shallow waters and river outlets are the most important feeding sites for seabirds. Sandy or rocky beaches and sea cliffs are important nesting sites.

Audouin's gull and the Mediterranean shearwater both breed solely in the Mediterranean. The Mediterranean gull is almost confined to the region for breeding. In addition, the European populations of the great black-backed gull and the slender-billed gull breed only in the Mediterranean and Black Seas [Ref 27].

11.4.6.2 Birds on the Mediterranean Coast

There is a diverse range of habitats along the Mediterranean coast that attract a large number of birds. Wetland areas contain the highest concentrations, and of these, deltas and lagoons support the most diverse community of bird species.

The globally threatened birds that have a strong dependence on Mediterranean coastal wetlands for breeding are the Dalmatian pelican, marbled teal and ferruginous duck. A significant part of the world population of the Dalmatian pelican breeds and winters in the Mediterranean coastal wetlands, especially lagoons and deltas. Populations are fragmented and found mainly in Albania, Greece and Turkey. The marbled teal breeds and also winters in lagoons and other wetlands in Spain, Morocco, Algeria, Tunisia, Egypt, Israel and Turkey. Several populations in other Mediterranean countries became extinct in the course of the twentieth century. Most of the world population of ferruginous ducks breed in large river deltas and other wetlands in Morocco, Spain, Italy, Albania, Slovenia, Croatia, Yugoslavia, Bosnia-Herzegovina, Greece, Turkey and Israel. The species migrates through or winters in lagoons and coastal marshes in France, Malta, Libya, Tunisia, Algeria, Egypt, Cyprus and the Lebanon.

Millions of birds cross the Mediterranean Sea twice a year during migration, usually at the narrowest point over the Straits of Gibraltar or via Sicily, but also via other islands such as the Balearic Islands, Corsica, Sardinia, Crete and Cyprus. The coastal wetlands become vital refuelling stops during this time, when birds are at their most exhausted and vulnerable. A number of globally threatened birds are known to migrate through the Mediterranean region. These include the critically endangered slender-billed curlew, the lesser kestrel and the lesser white-fronted goose. The slender-billed curlew has been recorded mainly in wetland sites in Greece, Turkey and Italy but also in Albania, France, Malta, Spain and Tunisia. Wintering curlews may occur on the coast of Tunisia, Algeria and Morocco. The Lesser Kestrel migrates through Malta, Cyprus, Egypt and Lebanon and the lesser white-fronted goose passes through the Evros Delta in Greece.

There are several other threatened species, which can occur in wetland areas quite close to or even on the coast, but are generally associated with habitats further inland. These include the white-headed duck, corncrake, Spanish imperial eagle, aquatic warbler and the greater spotted eagle.

Other species are of particular conservation concern because they are:

1 either close to qualifying as threatened, for example the delta-dwelling Pygmy Cormorant and white-tailed eagle; or

2 because their entire world population is confined to Mediterranean coastlines, for example Eleanora's falcon is found on rocky coasts. Six passerine birds, the Corsican nuthatch, the Algerian nuthatch, the Syrian serin, Marmara's warbler, the Cyprus pied wheatear and the Cyprus warbler, are confined to islands or inland areas in the Mediterranean region. Cyprus has been designated an Endemic Bird Area (EBA) by Birdlife International, a designation which illustrates conservation importance rather than any form of official status or protection [Ref 28].

11.4.6.3 Seabirds in the vicinity of the BTC Marine Terminal

There are no seabird colonies in the immediate vicinity of the proposed BTC Marine Terminal and Jetty. The nearest significant populations of seabirds are found on the shores of Yumurtalik Bay and the Cukurova delta, to the southwest of Yumurtalik (approximately 80km from the proposed BTC Marine Terminal). These are described in Section 11.4.8 below [Ref 29].

11.4.7 The intertidal zone

11.4.7.1 Rocky shores

Observations made in the supralittoral (ie splash) zone during winter and spring marine ecology surveys, [Ref 6] identified a high species diversity comprising: cyanophytes (*Clothrix* sp, *Microcoleus sp*); lichen (*Verrucaria amphibia*); gastropods (the snail (*Melaraphe (Littorina) neritoides*), the periwinkle (*Littorina punctata*), the limpet (*Patella sp*)) and crustaceans (the barnacle (*Chthamalus depressus*), the sea louse *(Ligia italica*). No seasonal variation was observed within this zone.

Plate 11.3 Example of Supra- and Midlittoral Stone

This midlittoral zone (ie the lower beach) consisted of highly adaptive species, resistant to desiccation, with the limpet *Patella caerulea* and the worm-shell *Vermetus* sp. as the most abundant organisms observed in this zone [Ref 6]. Again relatively little seasonal variation existed, though the alga *Enteromorpha* sp. was absent in winter.

Plate 11.4 Photophylic Algae on the Medilittoral Zone

11.4.7.2 Sandy shores

Aerial photographs taken of the proposed BTC Marine Terminal site and coastal area indicate that there is no evidence of significant coastal retreat. In addition, beach morphology suggests that there is a net northward transport of sediment. Two types of bottom structure were found on the sandy shores [Ref 6]:

- sand without vegetation and with scattered debris – no macrofauna were observed;
- sand with dry wracks – dead/decaying deposits of the red algae (*Jania rubens*) and *Caulerpa prolifera* providing a habitat for a variety of gammarid amphipods (fairy shrimp) and the sandhopper *Talitrus saltator*.

11.4.8 Protected Areas

11.4.8.1 General

Coastal habitats are increasingly being afforded protection in Turkey. Between 1989 and 1995, approximately 774km of coastline was identified for protection in Turkey. During 1995 alone, a total of 25% (1,332km) of the total Turkish Mediterranean coastline was declared under protection.

The only protected area within the vicinity of the proposed BTC Marine Terminal is the Yumurtalik Lagoons, which is designated as a Nature Reserve and protected under the Law on National Parks, number 2873. This law administers the designation of proposed Nature Reserves, prohibited activities within these areas and sets permission and penalty procedures.

The National Parks Regulations, number 19309, was published on 12th December 1986 and details the principle requirements set out in the Law on National Parks.

11.4.8.2 Yumurtalik Lagoons

Overview

This wetland complex, which is designated as a 1st Degree Natural Site, covers an area of 16,430ha and is situated between the mouth of the Ceyhan River and Yumurtalik Bay (see Figure 11.9). The site qualifies as an Important Bird Area (IBA) under the following Global and Regional (European) criteria.

- A4i (global criteria - congregations): the site is known or thought to hold, on a regular basis, >1% of a biogeographic population of a congregatory waterbird species;

- A4iii (global criteria - congregations): the site is known or thought to hold, on a regular basis, >20,000 waterbirds or >10,000 pairs of seabird of one or more species;

- B1i (regional criteria - congregations): the site is known or thought to hold less than or equal to 1% of a flyway or other distinct population of a waterbird species;

- B2 (regional criteria – species with an unfavourable conservation status in Europe): the site is one of the most important in the country for a species with an unfavourable conservation status in Europe (SPEC 2, 3) and for which the site-protection approach is thought to be appropriate.

The site comprises a complex of brackish and saline lagoons, salt and freshwater marshes, tidal mudflats, pastures, reedbeds (*Phragmites*), sand dunes and pine forest. Several large inlets connect the site to the sea. Saltmarsh areas have been converted to arable land in places and cattle graze on the extensive meadows to the west.

The Aleppo pine forest (*Pinus halepensis*) contains the Cretan date palm (*Phoenix theophrasti*), which is a lower risk – near threatened species on the IUCN 2000 Red List (Plate 11.5). There are only four known populations of this latter species in Turkey and it is considered endangered nationally, as it was previously found growing only in the vicinity of Marmaris. It is the only naturally occurring palm tree in Turkey. A number of other species found within this pine forest include, red pine (*Pinus brutia*), mastic tree (*Pistacia lentiscus*), common myrtle (*Myrtus communis*), Syrian privet (*Fontanesia phillaroides*), Broom heater (*Erica manupuliflora*).

Habitat cover is approximately 10% arable land, 5% forest and 85% wetland (which consists of coastal lagoons, mud and sand flats, salt marshes, sand dunes and beaches and water fringe vegetation). Existing land use activities include agriculture, fisheries/aquaculture, hunting, and tourism [Ref 26, 28, 30].

The full citation for the Yumurtalik Lagoons IBA is provided in Appendix B3.

Plate 11.5 Cretan Date Palm (*Phoenix theophrasti*) Growing near Aleppo Pine Forest at Yumurtalik

Yelkoma Lake

Yelkoma Lake is one of the many lakes within Yumurtalik lagoons and is connected to the sea by a narrow channel (see Plate 11.6). Although it is relatively deep, it almost completely dries out during summer. Marshland vegetation is well established at the southern end of the lake, comprising halophytic vegetation (salt tolerant), where glasswort (*Arthrocenmum fruticosum*) is dominant. Ecological surveys identified high biodiversity within the lake, with gilthead (*Sparus aurata*) and sea bass (*Dicentrarchus labrax*) the main fish species. The European pond turtle (*Emys orbicularis*), which is a lower risk – near threatened species on the IUCN Red List, was observed during survey work. Yelkoma Lake is also located adjacent to a site identified as a nesting site for both the Loggerhead turtle (*Caretta caretta*) and Green turtle (*Chelonia mydas*).

Plate 11.6 Yelkoma Lake in High Summer showing Sparse Halophytic (salt tolerant) Vegetation

Birds

Yumurtalik Lagoons are important for breeding waders and terns and large numbers of wintering waterfowl, although the area has reportedly poor feeding conditions.

Table 11.13 provides information concerning the main species that utilise the site and their importance criteria for which the site was designated an IBA.

Table 11.13 Birds Utilising Yumurtalik Lagoons

SPECIES	SCIENTIFIC NAME	STATUS	CRITERIA
Greylag goose	*(Anser anser)*	Winter	B1i
Wigeon	*(Anas penelope)*	Winter	A4i, B1i
Black francolin	*(Francolinus francolinus)*	Breeding	B2
Kentish plover	*(Charadrius alexandrinus)*	Winter / Breeding	B1i, B2
Little stint	*(Calidris minuta)*	Winter	A4i, B1i
Avocet	*(Recurvirostra avosetta)*	Winter	B1i, B2
Little tern	*(Sterna albifrons)*	Breeding	B2

A number of migrant waterbirds and passage migrants were observed during the Bird Survey, which included the IBA. Six nationally threatened species (Great egret, White pelican, Black stork, Glossy ibis, Garganey, Marsh harrier and White-tailed plover) and three species considered endangered in a European context (Spur-winged plover, collared pratincote and gull-billed tern) were recorded during this survey.

Conservation Issues and Threats

Threats from industrialisation and urbanisation are high and land to the east is already heavily industrialised. Although aquaculture/fisheries and agricultural intensification/expansion are considered as medium threats to the IBA site, there has been a dramatic decline in fish stocks as a result of unsustainable fishing practices.

Additionally, the use of large amounts of fertiliser and pesticide in agricultural areas, such as at Cukurova, poses significant problems to the site. Other threats include overgrazing, drainage, tourist development and hunting. Two large irrigation projects have been proposed, (the Asagi Seyhan Irrigation Project and the Irrigation Project for Yumurtalik and its Vicinity), which include provisions to prevent drainage water entering the lagoons. It is not expected that the Yumurtalik lagoons will be affected by the latter project, as the drainage channels to be constructed will not reach the lagoons (*Director of Ceyhan Branch of DSI, Adana Regional Directorate, pers comm.*). Furthermore, a management plan, passed in 1996, regulates all land-use in the delta and places restrictions on the construction of holiday homes.

11.4.9 Seasonal Sensitivities

11.4.9.1 Overview

Table 11.14 summarises the key seasonal sensitivities, which are further discussed below.

Table 11.14 Seasonal Sensitivities

Breeding												

11.4.9.2 Fish and Fisheries

There are an estimated 500 species of fish in the Mediterranean and the Gulf of Iskenderun is an important fisheries resource with extended spawning seasons due to its warm temperatures and a high primary productivity [Ref 6]. The majority of fish spawn 2-3 times a year in the Gulf, with Lessepsian migrants spawning 1-2 times a year. Yumurtalik lagoons is a particularly important area providing good habitat for spawning due to its shallow waters and lagoons and at certain times of the year, bans on bottom trawling and fishing are declared in this region by the Ministry of Agriculture and Rural Affairs [Ref 6].

There were no protected species found within the vicinity of the proposed BTC Marine Terminal and so only commercially important species are considered [Ref 6]. The spawning period extends between March and October for the majority of fish species and between April and September for Lessepsian migrants [Ref 6].

11.4.9.3 Turtles

Turtles represent a seasonal sensitivity, both in terms of nesting as well as overwintering.

The Green turtle (*Chelonia mydas*) is known to overwinter in the Gulf of Iskenderun, as well as nesting in the summer months. The nesting season of Green turtles is poorly defined and is very dependent on locality. It may extend from late spring to early autumn in the Mediterranean, though the peak nesting months in Turkish waters are not known.

The Mediterranean population of Loggerhead turtles (*Caretta caretta*) mate in late March-early June and nest throughout the summer (end of May to September), with a peak around mid July. Green turtles start nesting about two weeks later. Variations in the nesting season, due to weather conditions, have been observed in both species. Hatching is dependent on both species and temperature and occurs between 40 to 60 days after eggs are laid.

11.4.9.4 Birds

Although there are no seabird colonies in the immediate vicinity of the proposed BTC Marine Terminal and Jetty (see Section 11.4.6), Yumurtalik Lagoons are important for a number of breeding waders and terns, wintering waterfowl and a variety of passage migrants.

11.4.9.5 Marine Mammals

Although, there is relatively little information concerning the seasonal activities and distribution of marine mammals on the south coast of Turkey, (as described in Section 11.4.4), it is not anticipated that key activities such as cetacean calving occur in the Project area.

The monk seal is non-migratory and spends most of its time within a limited home range. The reproductive period is mainly between May and November and young are born, generally in September and October.

The presence of monk seals was not observed during ecological surveys and it is unlikely that they are present in the vicinity of the proposed terminal due to already high pressure from industry in the Gulf. However, the Mediterranean Gap Analysis undertaken by WWF identified the south coast in Turkey (ie the Cilician coast) as an important area for monk seal populations and one of thirteen key areas to protect [Ref 10].

11.5 MARINE ARCHAEOLOGY

Desk studies and preliminary consultations with the Ministry of Culture and the Adana Provincial Directorate on the Protection of Cultural and Natural Entities were undertaken during the Basic Engineering stage and the Scoping stage of the EIA process. Side scan sonar studies carried out during the Ceyhan Marine Terminal Feasibility Study indicated that there were no features on the seabed within the area studied that could be interpreted as archaeological features.

Furthermore, public consultation was carried out with local communities on areas and features of cultural value. This exercise include those identified as fishing communities, such as Golovasi, Sahil Sitesi and Incirli, as these would be most familiar with the seabed and the possibility of artefacts or structures present on it.

Consultations and survey work carried out in the area indicate that there are no known marine archaeological features.

11.6 HUMAN ACTIVITIES

11.6.1 General

Turkey's coastal areas are developing rapidly through urbanisation, industrialisation, tourism and shipping (see Figure 11.9). The Gulf of Iskenderun is already a heavily industrialised area, including the following types of industry:

- Toros Gubre Fertiliser Facility north east of the existing BOTAŞ Marine Terminal. Two jetties are located here – one extending out to approximately the 14m isobath and the other to the 13m isobath;
- BOTAŞ Dortyol Marine Terminal with a jetty extending to the 14m isobath;
- Delta Oil Terminal;
- Aygaz LPG Terminal;
- Iskenderun iron and steel works at Isdemir;

- Iskenderun coastline (several jetties and other industries present including the settlement of Iskenderun);
- NATO Pier;
- Yumurtalik NATO Port;
- Sugozu Power Plant: currently under construction and planned for commissioning November to December 2003. Approximately 615m of the jetty has been constructed.

In this subsection, an overview of current industrial activity in the vicinity of the proposed BTC Marine Terminal is provided.

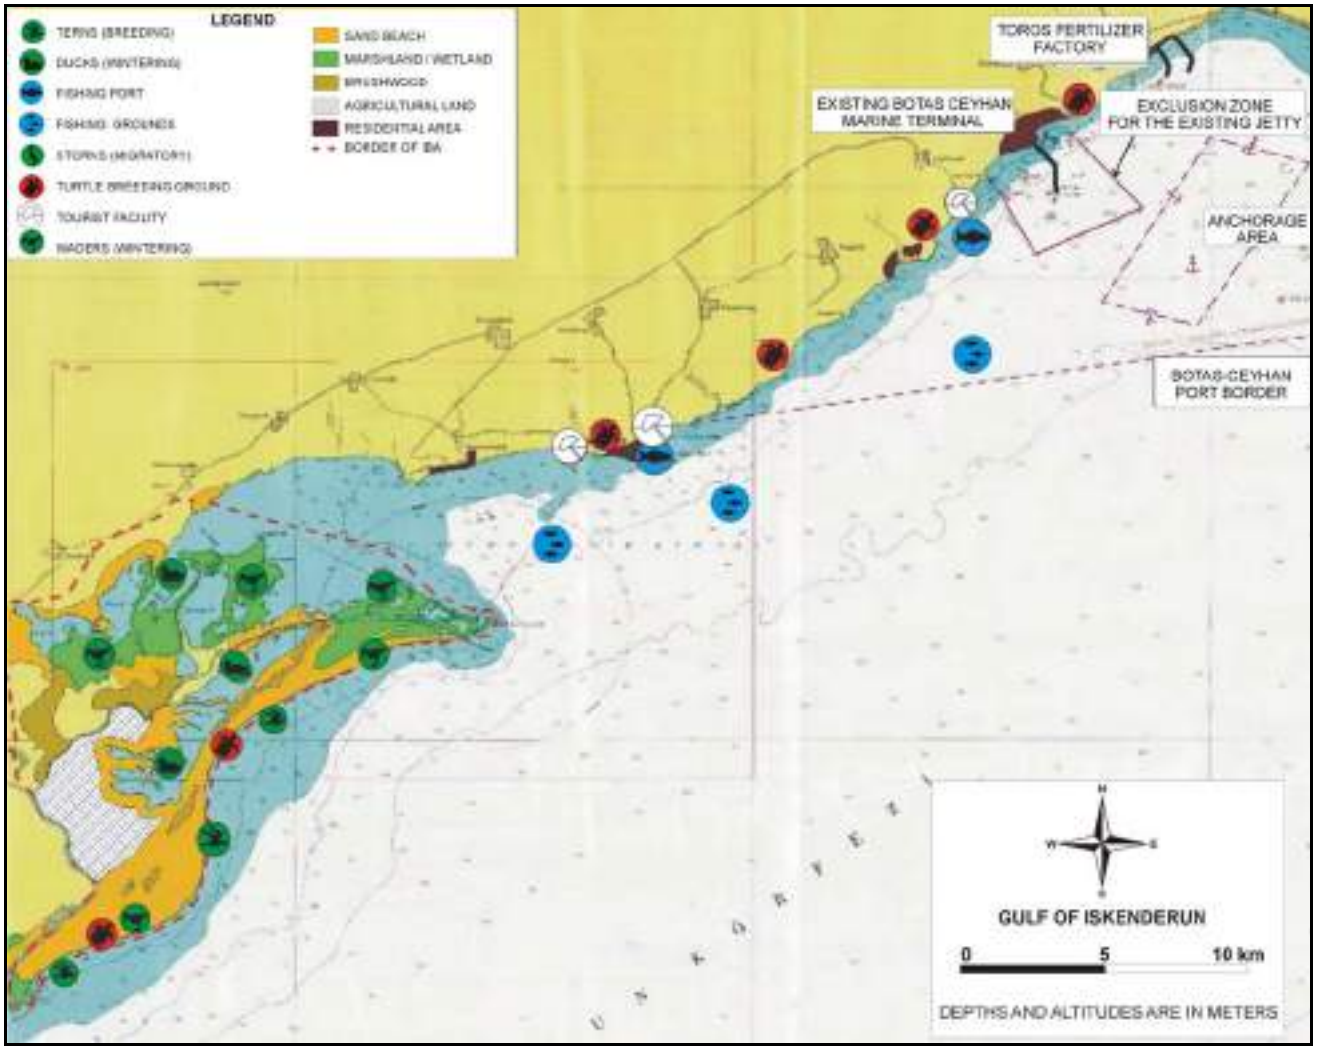

Figure 11.9 Coastal Sensitivity Map for the South West Coast of the Gulf of Iskenderun

11.6.2 Navigation and Shipping

11.6.2.1 Ceyhan Port

The Gulf of Iskenderun is a semi-enclosed body of water about 40km wide and 70km long, extending north eastward from the Mediterranean Sea. Ceyhan Port is situated at the north of the Gulf. The entrance to the outer harbour is located through an 820m opening and between a 1,300m long, north-south oriented breakwater and a jetty that extends westward from the shore at the north end of the port. Charted depths at the entrance are approximately 10 to 15m. A pilot is required for ships entering the harbour.

Anchorage for vessels is located west of the breakwater system that defines the limits of the inner and outer harbours. Access is unrestricted, with depths ranging from 10m to 25m and good holding on a mud bottom. Vessels waiting to berth at the existing BOTAŞ Marine Terminal, the Toros Gubre Fertiliser Facility or the BOTAŞ Dortyol Marine Terminal, anchor approximately 5.5km offshore. There is prohibited anchorage north of the BOTAŞ (Ceyhan) Harbour Limit, except within a designated anchorage area shown in Figure 11.10.

11.6.2.2 Tanker traffic

Tanker traffic at the existing BOTAŞ Marine Terminal was estimated in 1987 at 582 vessels with an average dead weight tonnage (dwt) of 113,718 tonnes. The number of vessels docking at the existing terminal in 2000 was recorded as 300 to 400 per year, with a maximum capacity of 1,000 tankers per year (*pers. comm.*). Tankers berthing at the Toros Gubre Fertiliser Facility and BOTAŞ Dortyol Marine Terminal were also estimated in 1987 at 165 vessels with an average dwt of 17,440 tonnes and 223 vessels with an average dwt of 23,816 tonnes respectively.

At the proposed BTC Marine Terminal, tankers will dock at a Jetty with two berths able to accommodate vessels of between 80,000 dwt and 300,000 dwt.

11.6.3 Recreation and amenity

Small pleasure craft are not permitted within the anchoring prohibited area around the existing BOTAŞ Marine Terminal. However, boat harbours lie on the north-east and south-west sides of the existing jetty. Furthermore, the rise of international and domestic tourism has led to an increase in tourist related vessel movements within the harbour area. The role of local fishermen in this activity and a key site of tourist interest are outlined in Section 10.

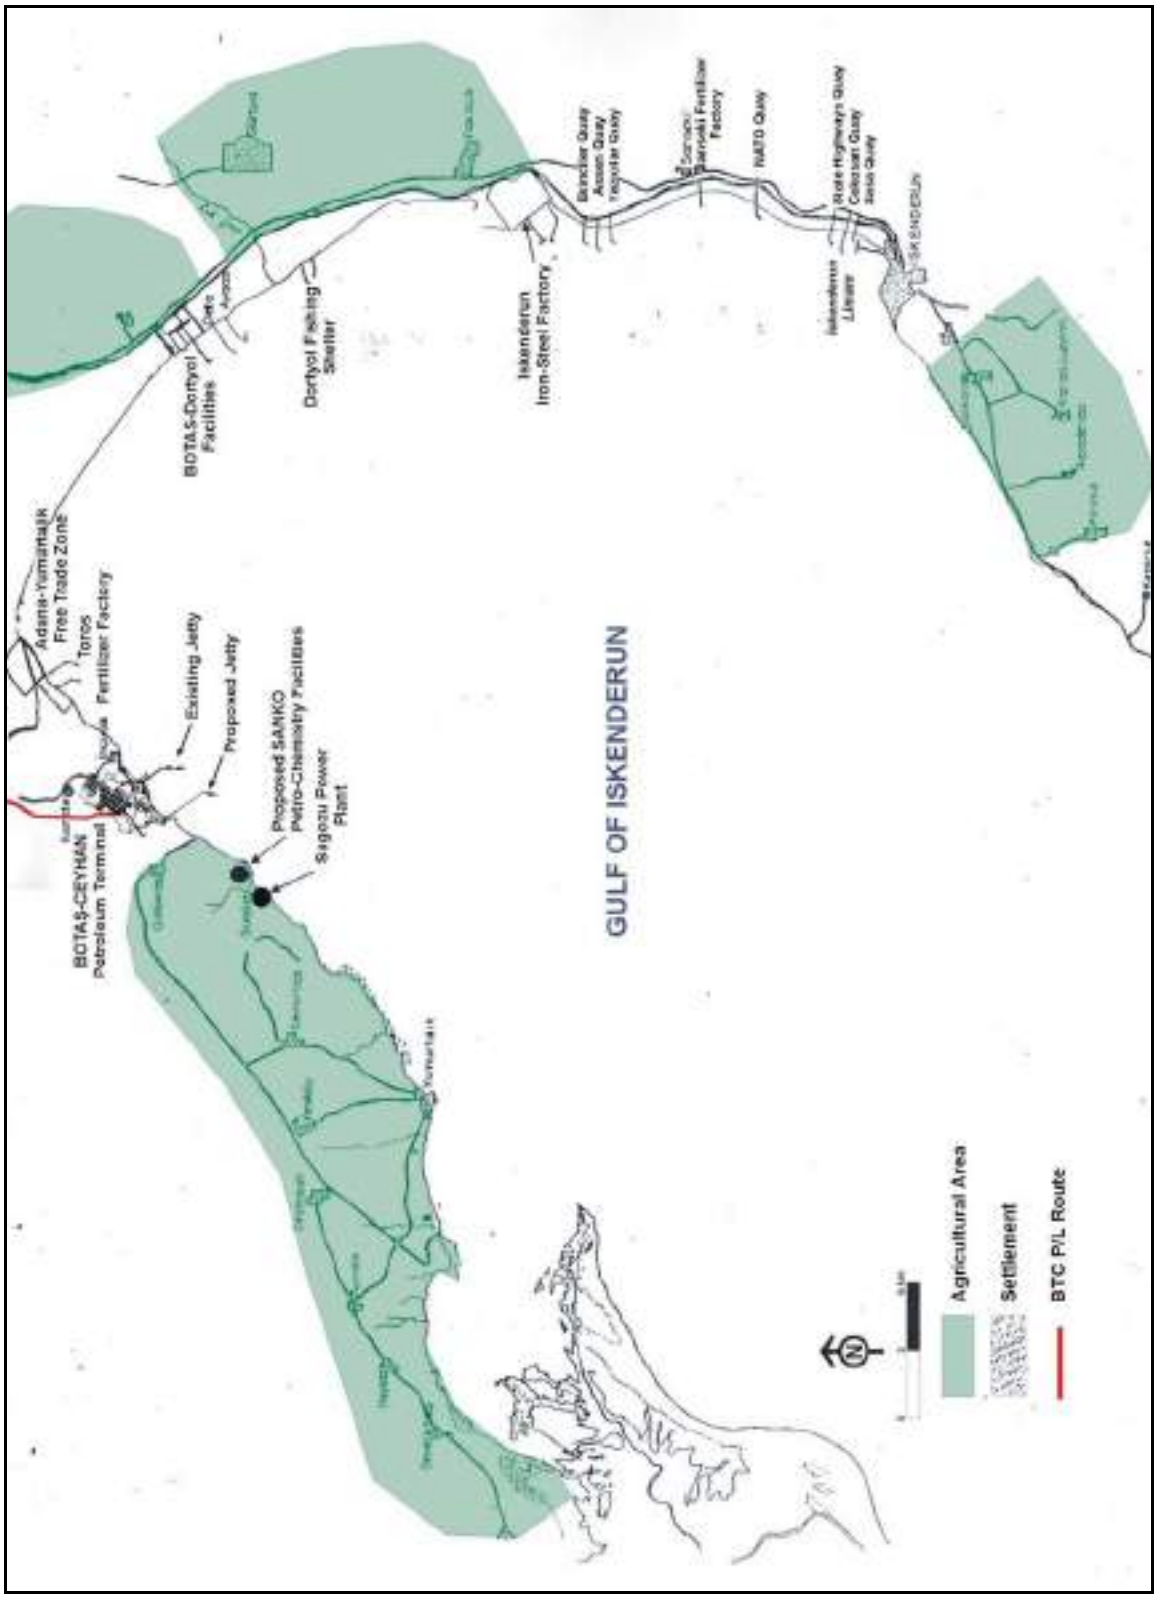

Figure 11.10 Existing Industrial Areas on the Coast of the Gulf of Iskenderun

11.6.4 Oil and gas activities

11.6.4.1 Existing BOTAŞ Marine Terminal

The proposed BTC Marine Terminal will be located adjacent to existing facilities on the coast of the Gulf of Iskenderun (see Figure 11.10) in Ceyhan. The existing terminal comprises a long steel jetty of approximately 2km with two loading platforms on the outer part of the jetty, providing four tanker berths. Tankers of up to 300,000 dwt and 22m draught can be accommodated.

The existing BOTAŞ Marine Terminal exports crude oil transported by pipeline from Iraq. The terminal also imports crude in smaller tankers from Dortyol, which is transhipped for refining offsite.

11.6.4.2 BOTAŞ Dortyol Terminal

The BOTAŞ Dortyol Terminal is situated approximately 20km northeast of Iskenderun and exports crude oil to the existing BOTAŞ Marine Terminal by tanker (see Figure 11.9). The terminal includes a T-headed jetty projecting from the shore of approximately 1.2km with a single berth.

11.6.5 Fisheries

11.6.5.1 General

Primary productivity in the Mediterranean is generally low compared to other seas, but can be locally elevated where conditions permit. In the Gulf of Iskenderun, primary productivity is 2-4 times higher than the adjacent sea area, averaging 115mg C (as carbon) $m^{-2}d^{-1}$. The Gulf is therefore an important fisheries resource with total fish production of over 21,000te yr^{-1}. Commercial fisheries in the Gulf include rainbow sardine (*Dussumeria aucta*), European anchovy (*Engraulis encrasicolus*), white sea bream (*Diplodus sargus*), yellowstripe barracuda (*Sphyraena chrysoteania*) and common pandora (*Pagellus erythrinus*) [Ref 6].

However, marine pollution and over-fishing are reducing fish resources. Turkey's marine waters are under pressure from heavy domestic maritime traffic, particularly in the Turkish Straits and marine pollution from land-based sources [Ref 9].

Important fishing grounds for a number of commercial fish species are found in this area, which are considered crucial for local fishing communities (see Figure 11.9, Section 11.4.8).

11.6.5.2 Fishing Patterns

Within the vicinity of the proposed BTC Marine Terminal, local fishermen from Golovasi/Sahil Sitesi and Incirli have identified (during focus group interviews) the principal fishing grounds comprising four main zones. Additional studies to identify fishing grounds with a wide range of stakeholders is on-going:

- Zone 1: between the Sugozu Thermal Power Plant and the existing BOTAŞ jetty exclusion zone (approximately 2.5 nautical miles[1] along the coast and up to 0.5 nautical miles offshore from Golovasi).

- Zone 2: between the existing BOTAŞ Jetty exclusion zone and the Sugozu Thermal Power Plant (approximately 2.5 nautical miles along the coast and from 0.5 to 2 nautical miles offshore).

- Zone 3: between the Toros Gubre Fertiliser jetty exclusion zone and the existing BOTAŞ jetty exclusion zone (approximately 0.5 nautical miles along the coast and up to 2 nautical miles offshore).

- Zone 4: over 2 nautical miles offshore.

Box 11.1 Main Fishing Locations/Settlements

Focus group workshops and interviews with local fishermen from Golovasi / Sahil Sitesi, Karatepe, Incirli, Haylazli, Deveciusagi during consultation enabled a broader understanding of the most frequently used fishing grounds in the vicinity of the BTC Marine Terminal. These results of those discussions are outlined below.

- *Golovasi/Sahil Sitesi*: fishermen fish daily in Zone 1 along the coast between Sugozu and the BOTAŞ exclusion zone and sometimes in Zone 2, depending on the season. Three to four times a month the fishermen fish in Zone 3 off the coast near Toros Gubre Fertiliser Facility. Zone 2 is the most important fishing ground for fishermen from Golovasi, because this is where shrimp, which sells at four times the price of other fish in the area, is caught.

- *Karatepe and Incirli*: fishermen fish daily in Zone 3 off the coast around the Toros Fertiliser facility and rarely (3-4 times a month) in Zones 1 and 2. Zone 3 is the most important fishing ground for Incirli fishermen (substantiated by an informal agreement they have with Golovasi fishermen that the latter will not use Zone 3 on a regular basis).

- *Haylazli and Deveciusagi*: fishermen fish in the vicinity of Sarigol, Adalar, Arap Bogazi, Dalyan, settlements and along the coasts of Yumurtalik and Haylazli.

Non-Local Fishermen: fish daily at least 2 nautical miles offshore in Zone 4. According to local fishermen, the non-local fishermen do not fish in Zones 1-3.

(1) [1] 1 nautical mile is equivalent to approximately 1852 metres.

Plate 11.7 Local Fishermen from Golovasi / Sahil Sitesi

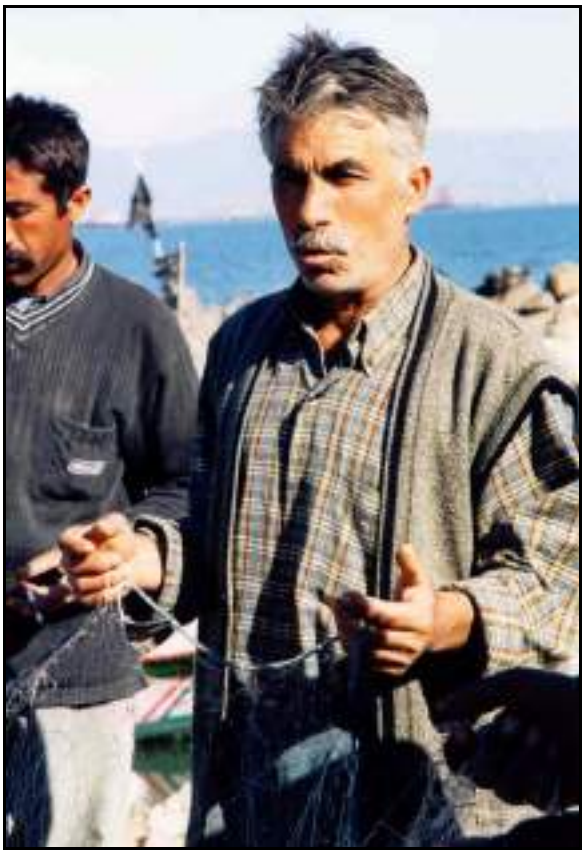

Plate 11.8 Fisherman from Golovasi / Sahil Sitesi

In addition to the activities of local fishermen, fishermen are also attracted to the Iskenderun Gulf from other regions, including Iskenderun, Samandag, Karataş, Hatay and the Black Sea (see Plate 11.9). It has been reported that the number of non-local fishermen has increased in the past ten years to approximately 60-70 boats, leading to elevated competition with local fishermen. Non-local fishermen tend to use more technologically advanced fishing equipment (eg radars) and have larger fishing boats. As a result, they are able to travel longer distances to fish (further than two nautical miles offshore). Non-local fishermen also typically fish using capital intensive line and radar methods, work for large fishing companies and live on their boats that dock in Yumurtalik port over night.

Plate 11.9 Non-Local Fishermen in Yumurtalik

In addition to the legal activities of local and non-local fishermen, discussions with local fishermen indicate that illegal fishing in the estuarine areas, which are important nursery areas for a range of commercial fish species, is of increasing concern (see Box 11.2). These activities were also cited as having direct consequences for sea turtle species (see Section 11.4.5 above). Marine restrictions also apply to local fishermen including the prohibitions of net fishing within the existing BOTAŞ Marine Terminal exclusion zone. However observations indicate net fishing constitutes an important method of fishing for local fisherman (see Section 12 and Plate 11.8).

Box 11.2 Illegal Fishing

The region is rich in estuarine pools and lagoons (referred to as 'fish ponds'). A recent law forbids the catching of fish from 'fish ponds'. However, local fishermen are reported to be catching small fish from these 'fish ponds' and selling them to fish farms in western Turkey.

The presence of an intense and sometimes illegal fishing effort along the south coast of Turkey is reportedly causing serious damage to fish stocks and other key species such as sea turtles.

Source: Fishermen from the Marine Terminal Survey Area

11.6.5.3 Catch statistics

Overall landings for Mediterranean fisheries in total are relatively modest (approximately 1.3 million te). However, Mediterranean fisheries resources are in a state of over-exploitation with over-fishing and fishing practices largely accounting for the impact on natural stocks and habitats.

The social survey of the fishing communities in the area indicated that shrimp (karides) is the most important marine species for all surveyed fishermen (as it is the most lucrative), followed by sea bass, blue fish, gilt-head bream and striped/ grey mullet. All these species are caught by fishermen from all five fishing settlements. However, lahos (logos), the most expensive type of fish, is only caught by fishermen from Golovasi/Sahil Sitesi. A number of fish species (eg tubara and karakulak) are caught solely by fishermen in Haylazli and Deveciusagi and other species (eg kayis and anchovies/ catal kulak) are caught solely by fishermen from Deveciusagi. Typically, shrimp is only caught in Zones 2 and 3, whereas the majority of other fish types are caught in all of the zones.

As indicated above, local fishermen use traditional nets that are cast in waters no more than 20-30m in depth; this generally equates to depths encountered within three nautical miles off the coast. The distances travelled by local fishermen is further constrained by the small size of their boats, the lack of sufficient engine power to enable long distance travel, the poor condition of the boats (often not sufficiently sea-worthy), the high cost of fuel, the lack of enclosed sections on their boats, which would enable night fishing, and competition with non-local fishermen (see Plate 11.10). By contrast, non-local fishermen use capital-intensive line and radar methods and are able to fish in deeper water.

Plate 11.10 Local Fishing Boats, Golovasi Port

Amongst the local fishermen, the average daily catches per species[1] per surveyed household was reported as follows:

- striped mullet (kefal) (2-10kg);
- sea bass (levrek) (1-5kg);
- gilt-head bream (cupra) (2-4kg);
- muskov (1-2kg); shrimp (karides) (1-3kg);
- shrimp (karides) (1-3kg);
- blue fish (lufer) (4-5kg);
- mackerel (istavrit) (1-3kg);
- waker/lahos (logos) (7-10kg);
- sole (dilbaligi) (4-5kg) ;
- tubara (7-23kg);
- golden mullet (sarikulak) (4-6kg);
- corb (karakulak) (1kg);
- sea bream (tranca) (2-5kg);
- kayis (2kg);
- bildircin (2kg);
- sabun baligi (5kg);
- anchovy (catal kulak) (4kg).

Respondents were noticeably hesitant to declare their catches, and it is likely that these data are underestimated for fear of taxation. Of the amount caught, each fisherman takes home an average of 1-2 kilograms for household consumption.

The social survey indicated that local fishermen fish for a maximum of five hours per day. Generally they release their nets in the late afternoon, between 5pm and 7pm and collect them the next morning between 7am and 10am. There are usually between 3-4 fishermen from different households on each boat catching all fish types, with the exception of shrimp farming which is usually undertaken by 2-3 fishermen from different households on each boat and 2-3 teenagers (school-age) who are involved in cleaning the nets on shore (see Box 11.3).

Box 11.3 Daily Catch

Most fishermen from Golovasi catch shrimp. This sells at approximately 15 million TL per kilogram. Usually one boat comprising on average three individuals (from different households) collects three kilograms of shrimp a day. Revenue is divided between the three respective households.

Source: Household Questionnaire, Marine Terminal Area

The local fishermen claim that the involvement of young people helps train them to become fishermen in the future. The wives of some of the fishermen (if they have skills useful for fishing related activities) also work to sort and arrange the nets (see Plate 11.11). The average age of local fishermen ranges between 35-40 years old, whereas non-local fishermen on average tend to be slightly younger at 30 years of age.

[1] The names of the majority of fish species (as provided by the fishermen) represent local terminology for the species listed.

Plate 11.11 Fishing Family in Golovasi / Sahil Sitesi Port

The social survey findings suggest that the fishing season for the different marine species varies throughout the year and peak/ off peak seasons cannot easily be identified. The key months for the main species of fish caught are as follows:

- Striped mullet: all year round;
- Sea bass and blue fish: between November and January;
- Gilt-headed bream: between June and September;
- Shrimp: between March and October;
- Muskov: between December and February;
- Lahos: all year round with the exception of July and August when fishing of this species is forbidden;
- Sole: peak months between November to January.

However, fishermen from both Golovasi and Incirli stated that there had been a decline in catch size over the past five years and attributed this to the following:

- an increase in environmental pollution as a result of industrialisation along the coast of the Iskenderun Gulf;
- trawling by non-local fishermen from the Black Sea and other regions;
- fish being attracted to lights on the existing BOTAŞ Jetty, thus entering the exclusion zone where fishing is prohibited;
- increased numbers of fishermen, due to a lack of alternative activities;
- over-fishing.

Some of the commercial and social implications of the decline in the fishery resource are illustrated in Box 11.4.

Box 11.4 The Decreasing Profitability of Fishing

In the early 1970s, an important economic activity in Golovasi was animal husbandry. However, the settlement lost most of its land during expropriation to establish the existing industry. Therefore more residents turned to fishing. Yet profitability has decreased due to inappropriate fishing activities of non-local fishermen, over-fishing and a rise in input prices. This has contributed to the rise in debts of fishermen to fishing companies.
Source: Fishermen from Golovasi

The problems faced by fishermen are impacting upon the career choice of the younger generations. *'The sons of fishermen are not becoming fishermen'.*
Source: Mayor of Yumurtalik Municipality

11.6.5.4 Commercial Significance

Fishermen from Golovasi and Incirli that land catches that are surplus to their domestic needs sell their surplus either within the settlement or to local traders in Yumurtalik). The local traders are registered small-scale entrepreneurs commonly functioning as a family business and composed of 1-2 people. They operate using trucks and travel everyday to Golovasi and other fishing grounds to buy fish from local fishermen. These local traders then sell the fish to fishing companies in Yumurtalik, Incirli, Adana and to larger companies in Izmir, Ankara and Istanbul. Many of the fishermen have informal contracts with local traders whereby they obtain equipment from the local traders and in return sell their catch to them (see section on debts in Section 10). Contracts between fishermen and the local traders preclude fishermen from selling directly to fish restaurants (eg in Sahil Sitesi and Incirli).

Additional information on importance of fishing as a source of both employment and livelihoods is provided in Section 10.

Table 11.15 below provides a summary of fishing activities for the existing BOTAŞ Marine Terminal area.

Table 11.15 Summary of Fishing

SETTLEMENT	ONE OF TWO MAIN SOURCES OF INCOME (% HH)	MAJOR FISHING GROUNDS USED[1]	AVERAGE CATCH* & MAIN FISH TYPE	USE OF FISH	AVERAGE COSTS & REVENUES /HH/SEASON (M TL)**	MAIN FISHING MONTHS
Golovasi	38%	Primarily zones 1 and 2, although zone 2 is important. Infrequently in zone 3.	Waker / Logos (10) Sea bass (5) Blue fish (5)	Sold to fishing companies	Costs : 108 – 800 m TL Total revenues: between 125 and 834 m TL	March-September
Sahil Sitesi	25%	Primarily zones 1 and 2, although zone 2 is important. Infrequently in zone 3.	Waker / Logos (10) Sea bass (5) Blue fish (5)	Sold to fishing companies	Costs : 108 – 800 m TL Total revenues: between 125 and 834 m TL	March-September
Incirli	26%	Primarily zone 3. Infrequently in zone 1 and 2.	Mullet (2) Muskov (1.5) Bream (1.3)	Majority sold to fishing companies (some household consumption)	Total costs between: 50 and 375 m TL Total revenues between: 100 and 250 m TL	October to November (mullet all year round)
Karatepe	3%	Primarily zone 3. Infrequently in zone 1 and 2.	-	-	-	-
Haylazli	37%	Sarigol, Adalar, Arap bogazi, Dalyan and coasts of Yumurtalik	Kefal (10) Tubara (23) Levrek (5) Sarikulak (5) Tranca (5)	Majority sold to fishing companies (some household consumption)	Total costs between: 29 and 292 m TL Total revenues: 34 and 250 m TL	Generally all year round
Deveciusağı	80%	Sarigol, Adalar, Arap bogazi, Dalyan and coasts of Yumurtalik	Kefal (8) Tubara (7) Levrek (5) Lufer (5)	Majority sold to fishing companies (some household consumption)	Total costs: between 28 and 250 m TL Total revenues: between 35 and 420 m TL	Generally all year round

*Average catches in kilograms per day
** Section 12.9.2 provides an explanation of the relationship between costs and income earned.

Source: Household Survey (HH = household)
Note: The above figures are based on estimates by individual household members and therefore there may be some inconsistencies in these estimates. Fishing activities were not reported by respondents in Sugozu, Karayilan and Hamzali as a main source of income.

[1] Details of each zone is provided in the text.

13 MARINE TERMINAL - MARINE IMPACTS AND MITIGATION

13.1 INTRODUCTION

13.1.1 Basis for the assessment

This section identifies the marine and coastal impacts associated with the construction, commissioning and operation of the crude oil handling and storage facilities at the proposed BTC Marine Terminal. The significance of identified impacts is assessed in light of mitigation measures incorporated during the planning and design development process. Where appropriate, specific control measures are described in greater detail.

The potential impacts have been derived through scoping and consultation activities and also through the consideration of potential impacts in light of the assessment significance criteria set out in Section 3 of this report.

13.1.2 Scoping

Preliminary details concerning the existing environmental baseline were established during initial scoping activities, which were undertaken between September 2000 and January 2001. This overview highlighted potential areas of concern and established the need for areas of further investigation. Potential areas of concern included several ecologically important areas for birds and turtles.

During Consultation, which commenced in August 2001, a number of perceived benefits and concerns were raised. These issues varied between stakeholders (from local residents to NGOs to local authorities) and are listed in Section 12. Concerns that relate to the marine environment were limited to potential impacts to fisheries and the effects associated with a potential increase in pollution from tanker activity.

13.1.3 Potential impacts

The possible interactions between marine receptors and the activities associated with the construction and operation of the proposed BTC Marine Terminal are numerous. However, the mitigation of potential impacts through an integrated approach to the design process, combined with the relatively low number of marine receptors, means the potential for impacts is limited in scope, particularly during routine construction and operating scenarios. These potential impacts are presented in Table 13.1.

Impacts due to accidental events (ie oil spills) are discussed separately in Section 14 of this report.

The assessment of each of these potential impacts is presented in the subsections that follow, although the secondary socio-economic impacts on fisheries, tourism and recreation, together with visual impacts are addressed in Section 12.

Table 13.1 Summary of Potential Impacts

MAIN ACTIVITIES	POTENTIAL IMPACTS
Jetty Installation: piling cement discharge vessel discharges and emissions exclusion zone	• physical disturbance of seabed • impacts to water and sediment quality • impacts to marine organisms • noise impacts on marine fauna • noise impacts on humans • exclusion of fishing vessels • navigation interactions • disposal of solid wastes • impacts to tourism and recreation
Commissioning: pressure test discharges	• physical disturbance to seabed • impacts to marine organisms • impacts to water quality • disposal of solid wastes
Operation: exclusion zone vessel discharges vessel emissions	• impacts to water quality • impacts to atmosphere • impacts to marine organisms • noise impacts on marine fauna • exclusion of fishing vessels • navigation interactions • disposal of solid wastes • impacts to tourism and recreation • visual impact

13.2 AIR QUALITY IMPACTS

13.2.1 Introduction

This section identifies potential impacts to air quality as a result of marine based activities associated with construction and operation of the BTC Marine Terminal. Impacts to air quality have been identified when an activity is predicted to result in a change to the baseline situation. The significance of an impact has been determined using the impact significance criteria set out in Section 3 of this report. The significance criteria are largely based on the Turkish and World Bank air quality standards. Mitigation measures have been identified and details are presented in this section.

13.2.2 Construction impacts and mitigation

Vessels and plant will generate atmospheric emissions during the installation and commissioning phases as a result of the combustion of marine diesel and fuel oil.

There will be a significant amount of activity from construction and support vessels during the installation and commissioning stage. The construction fleet will comprise approximately six vessels as follows:

- a crane barge;
- a barge with piling equipment;
- two support barges;
- two tug boats.

It is assumed that the construction fleet will use roughly 50te of fuel per day in total. Using generalised emission factors [Ref 1] and assuming vessels are using 1% sulphur fuel oil, this equates to the following approximate annual emissions:

- 3.0t NO_x;
- 4.0t CO;
- 163t CO_2;
- 1.0t SO_2;
- 0.2t hydrocarbons.

Distance dispersion will further serve to reduce impacts to coastal receptors, which will generally be well in excess of 2km from the emissions sources. Given the temporary, intermittent and dispersed source of these emissions, as well as the fact that they will be relatively remote from any sensitive receptors, only minor air quality impacts are predicted during construction.

13.2.3 Operational impacts and mitigation

Atmospheric emissions from tankers' engine exhausts will be relatively minor and will be an intermittent source during operation. A modern tanker uses relatively little fuel while berthed. Given that the tankers are loading, rather than offloading oil, their fuel requirement will be even lower. Using typical emissions factors [Ref 1], and assuming both berths are in regular use, the anticipated annual emissions from tanker burning 1% sulphur fuel oil at the proposed facilities are as follows:

- approximately 22t NO_x;
- approximately 3t CO;
- approximately 1,200t CO_2;
- 7t SO_2;
- 1t hydrocarbons.

While these emissions are not insignificant (for example an average household generates less than 1% of the equivalent CO_2), they are very low in the context of shipping. A tanker underway can use 60-200te of fuel per day, with commensurate increases in emissions, thus in the context of marine transport, the rate of emissions from tankers berthed at Ceyhan is considered minor.

Distance dispersion will ensure that air quality impacts to coastal receptors will be minor.

13.3 PHYSICAL IMPACTS TO THE SEABED

13.3.1 Introduction

This section identifies potential physical impacts to the seabed as a result of marine based activities associated with the construction and operation of the BTC Marine Terminal. Potential impacts to the seabed will result from any interaction between marine project components (eg the jetty) and the seabed. Such interactions are limited to minor disturbance

due to piling of the steel structure (ie construction impacts), as well as permanent loss of seabed habitat due to the stone causeway (operational impact). In the absence of criteria to determine the significance of impacts to the seabed, the impacts are based on professional judgement (see Section 3).

13.3.2 Construction impacts

The principal activity that has the potential to cause physical impacts to the seabed is likely to occur during jetty construction, in particular the installation of the 365m rock approach causeway from the shore and piling the legs of the trestle causeway extension. Construction of these structures is anticipated to involve the following key components.

- Construction of the causeway will be from shore, with rock material being dumped progressively seawards as the causeway is extended.
- Rock armour will be placed on the causeway from a barge, probably using a crane.
- Piling for the jetty will be carried out from a barge. Piles will be driven, though occasionally it may be necessary to drill through the piles to fit anchor bolts (though this is expected on less than 5% of piles).
- The deck and superstructure of the jetty will be prefabricated and placed using a crane barge.

Installation of the approach causeway will cause direct disturbance impacts to the seabed occupied and immediately surrounding the causeway structure (approximately 0.5ha). In addition, a total of 446 piles (approximately 1.5m diameter) and 36 piles (approximately 1.2m diameter) will be installed. The total pile footprint will result in disturbance to approximately 0.08ha of seabed.

Generation of localised, temporary turbidity plumes around the causeway and piles will be inevitable during construction activity. The majority of the piles will be driven rather than drilled, thereby minimising the re-suspension of seabed material. It is predicted that any increase in turbidity will be temporary in nature and will be well within the natural turbidity variation of the system. Disturbance impacts to the seabed during construction are therefore considered to be minor.

13.3.3 Operational impacts

Once construction is complete, the causeway will occupy less than 0.4 ha of shallow subtidal habitat (in a narrow strip from the shore down to the 5m isobath). This area represents a small area of seabed when considered in the context of the wider area. The physical presence of the causeway has the potential to cause changes in sediment dynamics locally and therefore to the ecology of the surrounding marine habitats. These impacts are discussed in Sections 13.4 and 13.6 respectively.

13.4 IMPACTS TO COASTAL PROCESSES

13.4.1 Introduction

This section identifies potential impacts to coastal processes as a result of marine based activities associated with construction and operation of the BTC Marine Terminal. Impacts to coastal processes are identified as occurring when an activity is predicted to result in a change

to the baseline situation. Any hard structure on the seabed or in the sea has the potential to affect microcirculation and associated sediment transport patterns. The extent of this impact relates to the precise nature of the structure as well as to the prevailing hydrodynamic regime and the precise composition and morphology of the seabed. In the absence of any guidelines or standards, professional judgement is used in order to assess the potential impacts to coastal processes.

13.4.2 Construction impacts and mitigation

There is only a limited scope for impacts to coastal processes as a result of the construction of the marine project components. Rock dumping for the causeway may cause a minor localised impact as the causeway grows. As with the operational impact of the causeway (see below), this is considered a minor impact.

13.4.3 Operational impacts and mitigation

There have been no reported erosional impacts from the existing numerous jetty structures that have been constructed as part of other industrial developments in the Gulf of Iskenderun. This is typically the case with open pile constructions, even those of the scale of the proposed jetty. Nevertheless, the configuration of the proposed BTC jetty differs from some other structures in that it incorporates a stone causeway/footing, as opposed to being an entirely 'open' steel structure.

Longshore drift is evident on the sandy beaches in the area (as seen in the aerial photograph reproduced in Figure 10.8). There is a consistent build up of sand on the southern side of headlands and hard coastal structures, indicating a net northward sediment transport regime. It is thus expected that sediments (primarily sand) will build up on the southern flank of the causeway, leading to the formation of a small sandy beach. This may in turn starve the existing BOTAŞ beach to the north of the proposed jetty, which as a result, may experience a slight decrease in size. Due to the small size of the causeway, worst case morphological impacts are anticipated to be moderate.

Monitoring of seabed levels and shoreline morphology will be conducted to determine the extent of changes on coastal morphology caused by the structure. If the changes are viewed to be significant, remedial action will be taken to replenish the existing BOTAŞ beach to the north of the proposed BTC Jetty structure.

13.5 IMPACTS TO WATER QUALITY

13.5.1 Introduction

This section identifies the potential for impacts to marine water quality as a result of construction, commissioning and operation of marine components of the BTC Marine Terminal. In addition, the impacts from terrestrial discharges to sea have also been identified and assessed. An impact to marine water quality is identified when an activity is predicted to result in a change to the baseline situation. The significance of an impact has been determined using the impact significance criteria set out in Section 3 of this report. The significance of any potential impact to marine water quality will ultimately depend on the use of the resource (eg for fishing, bathing) or its importance to ecology or amenity and the magnitude of the change caused by the Project. The significance criteria are largely based on World Bank and Turkish standards for each category of impact. Where no standards are available, professional judgement has been used. Mitigation measures have been identified and details are presented in this section.

13.5.2 Construction impacts and mitigation

13.5.2.1 Effluents

The principal effluents that will arise during construction of the marine terminal will comprise:

- sewage/grey water from the construction workforce (on land);
- untreated drainage from uncontaminated areas;
- treated drainage from potentially contaminated areas;
- standard vessel discharges (drainage, sewage).

Sewage and grey water generated at the main construction camps by the construction workforce will either be tankered to the municipal sewage works where it will be treated or it will be treated on site. If the latter option is used, sewage sludge will require subsequent disposal. In remote locations away from the main construction camps, chemical toilets will be used. These will be emptied on a regular basis by a licensed waste contractor. As no wastewater will be discharged to sea, there will be no impacts to marine water quality.

At present there are several disposal options for the uncontaminated and treated drainage, including disposal to sea. Untreated drainage will be limited to rainwater, sea spray run-off, etc from uncontaminated areas (eg the causeway under construction) and this will have no effects on the water quality and ecology of the receiving waters.

Drainage from potentially contaminated areas (eg vehicle washing areas, fuelling areas, machinery areas, roads, etc) will be routed to the oily water system for treatment. The preferred disposal route has not yet been finalised, however if treated water (oil in water content typically less than 15 mg l^{-1}) is discharged to sea, this will disperse rapidly. Impacts are therefore predicted to be minor under worst case scenarios.

Construction vessels used during construction will produce standard wastes and discharges typical of any vessel at sea. These will be managed according to Turkish and international regulations (specifically MARPOL 73/78) and will not be discharged within 12 nautical miles (21.5km) of land. Although discharges will not take place within the terminal vicinity, the following criteria will be met:

- Sewage will be comminuted and disinfected prior to discharge, which will not take place within 12 nautical miles from shore. Vessel sewage discharges will meet the following criteria:

  - BOD < 40 ppm;
  - Suspended solids < 50 ppm;
  - coliforms < 200 per 100 ml.

- Drainage, particularly that from ship machinery spaces, will be treated to ensure that oil in water does not exceed 15 ppm.

If the relevant regulations are followed and the standards met, impacts to the marine environment will be localised and minor in nature.

13.5.2.2 Solid wastes

Land based sources

Solid wastes will comprise a variety of substances, but can be categorised broadly into four groups:

- uncontaminated materials, including packaging, paper etc;
- kitchen wastes, predominantly comprising food scraps;
- clinical waste, potentially including bandages/dressings, used syringes and sharps;
- potentially contaminated materials, including oily rags/swabs, paint containers etc.

All solid wastes will be shipped offsite for appropriate disposal by licensed contractors according to the provisions of the Waste Management Plan (see Appendix C3). No solid wastes will be disposed of to sea or at locations where they could be transported to the sea by the wind or by surface run-off. Impacts to marine water quality from either construction or operation of the proposed facilities will be minor.

Construction vessel wastes

No trash will be disposed of overboard. Uncontaminated and other non-hazardous wastes will be stored for appropriate disposal onshore.

Kitchen wastes from construction vessels will be macerated and discharged overboard (consistent with MARPOL requirements, ie comminuted to pass through a 25mm grating and not discharged within 3 nautical miles from land), where they will disperse and degrade naturally. Any such discharge will not take place in port and will have no impact to marine water quality. Clinical wastes and potentially contaminated materials will be packaged and returned to shore for appropriate disposal by a specialist contractor. No special wastes will be discharged to the marine environment.

No impacts to the marine environment from disposal of solid wastes are therefore anticipated.

13.5.3 Disturbance to marine sediments

Localised disturbance to sediment during the construction of the approach causeway and trestle jetty structure has the potential to cause water quality impacts through the disturbance of potentially contaminated marine sediments. As the sediments in the vicinity of the causeway are not contaminated, secondary impacts to water quality are predicted to be minor at most.

13.5.4 Commissioning impacts and mitigation

It may be necessary to discharge the loading line hydrotest solution to sea. This will comprise approximately 4,300m^3 of inhibited seawater (if both are discharged together), ie seawater containing corrosion inhibitor or oxygen scavenger. The discharge will take place from the end of the jetty to maximise dispersion. Given this, and the low concentration of additives (residual levels of corrosion inhibitor will typically be present in concentrations of a few ppm, which is not toxic to marine life) in the discharge, impacts to the marine environment are anticipated to be minor on the basis that it is a temporary one-off event and that:

- chemical additives will be selected for their low toxicities to marine life and will be used at concentrations and discharged at a rate which will not cause harmful effects to

marine ecology beyond the immediate discharge mixing zone (ie a few tens of metres)

- the discharge will be at the seaward end of the jetty, into water with good depth and dispersion characteristics.

13.5.5 Operational impacts and mitigation

13.5.5.1 Effluents

The majority of aqueous wastes arising from marine terminal operations will be treated and discharged onshore.

Oily effluent water and contaminated surface drainage will arise from jetty operations. These will be treated to the required standards (as cited in Appendix D) in an oily waste separator and discharged to sea. A discharge of this volume flow and quality will have minor and very localised impact on water quality (and ecology). Sewage and grey waters will be retained in a tank and periodically transferred to the main wastewater treatment system at the onshore terminal site for treatment (see Section 9.4.13.3).

Tankers will produce standard wastes and discharges typical of any vessel at sea. These will be managed according to Turkish and international regulations (specifically MARPOL 73/78). Only segregated ballast tankers will berth at the proposed jetty, thus any ballast discharge will comprise clean water. There are no other anticipated discharges from vessels during the operational phase, thus only minor impacts are predicted from this source.

13.5.5.2 Solid wastes

Solid wastes during the operation of the proposed jetty and associated facilities will be managed in the same way as construction wastes, ensuring that there is no disposal to the marine environment and that all wastes are responsibly and appropriately disposed of in compliance with the Waste Management Plan (Appendix C3).

No environmental impacts from solid wastes associated with the marine facilities are predicted.

13.5.5.3 Antifouling treatment

Biofouling of all the submerged structures and those in the splash zone will inevitably occur. Biofouling can take place rapidly, with observable fouling communities being established within weeks on certain surfaces. Typically, bacteria and algae are the first organisms to settle, followed by larger algae, barnacles, tube-building worms, bryzoans and mussels. Eventually, a wide variety of animals may inhabit the community, including crabs and shrimps.

A well-developed fouling community has several implications for marine engineering of the jetty. The additional weight of a fouling community can be significant and static structures need to be designed to allow for this additional load otherwise chemical or physical antifouling treatments will be required. The facility will be designed to allow for the additional weight of a fouling community, therefore there will be no antifouling treatment required and thus no impacts will occur.

13.6 IMPACTS TO MARINE ECOLOGY

13.6.1 Introduction

This section identifies potential impacts to marine ecology as a result of construction and operation of marine components of the BTC Marine Terminal. Impacts to marine ecology are identified when an activity is predicted to result in a change to the baseline situation. The significance of an impact has been determined using the impact significance criteria set out in Section 3 of this report. The significance of any potential impact on ecology will ultimately depend on the status of the habitat or species and the predicted change as a result of an activity. The scale of an impact is generally subjective and often difficult to quantify, hence the significance of the impacts must quite often be based on professional judgement. Mitigation measures have been identified and details are presented in this section.

13.6.2 Construction impacts and mitigation

13.6.2.1 Physical disturbance

Disturbance to the seabed resulting from construction of the approach causeway and trestle jetty structure (Section 13.3) has the potential to result in localised sediment plumes. Sediment plumes and increased turbidity will result in some smothering to habitats and species in the vicinity of the proposed jetty structure. Organisms such as filter feeders are more susceptible to smothering than others, although many mobile species will simply move away.

Marine ecological data indicate that the diversity of benthic communities over the majority of the footprint of the jetty is low. Furthermore, the existing benthic community is pre-adapted to a certain degree of disturbance, as available data indicate that the seabed is mobile under prevailing natural conditions. Shallow water communities dominated by opportunistic species, as are present in this location, are anticipated to recover in 2-3 years.

An area of approximately 0.5ha in total will be permanently lost due to the presence of the causeway structure and piles supporting the trestle jetty. This represents only a small area of seabed in the context of the wider area. As no rare or protected species were noted during the marine surveys [Ref 2] and the faunal assemblages noted are typical of the wider area, the significance of habitat loss is anticipated to be minor.

The causeway structure will provide a hard substrate that will be colonised by hard bottom dwellers such as seaweeds, crabs and barnacles, thus increasing the biodiversity in the vicinity of the jetty structure and providing a refuge and feeding area for a number of small organisms and fish.

In the long-term geomorphological changes associated with the physical presence of the causeway and jetty piles will provide both new areas for colonisation and minor loss of existing habitats. Impacts will be localised and the net impacts to fauna are anticipated to be positive.

13.6.2.2 Acoustic disturbance

Characteristics of underwater noise

For a sound signal to be detected, it must contain sufficient energy to exceed any ambient noise present at frequencies near the signal frequency. The signal to noise ratio (at the receiver) is determined by the source level, the transmission through air or water and the

ambient noise level. The potential effects of anthropogenic noise on marine fauna may occur in a zone much smaller than implied by signal to noise ratios considerations alone, due to the varying responsiveness of different animals.

Generic impacts of noise on marine biota

The potential effects of noise on marine organisms can be categorised as follows:

- potential for changes in behaviour (including avoidance and attraction);
- potential for interference with acoustic communication;
- potential for physical damage (including damage to hearing apparatus).

Mobile fauna may exhibit behavioural changes, however, these are often hard to detect. Behavioural changes will typically involve a cessation of normal activities and the commencement of avoidance or 'startle' behaviour as a result of the detection of sound from marine construction activity. Continued detection of noise activity by organisms often results in habituation to the sound, followed by a re-commencement of normal behaviour.

Interference with sounds produced by animals for communication purposes is also difficult to assess, but is likely to result in the temporary cessation of sound production, or a muffling of sounds.

Physical damage can arise from the differential rate of transmission of sound pressure waves through tissues of varying densities. The effect is particularly marked at interfaces between tissues and gas-filled cavities, for example, the swim-bladders of fishes or the lungs of mammals. The sound-receiving apparatus of most organisms is generally comprised of sensory hair cells, which are extremely sensitive to vibrations. Over-stimulation of these can potentially lead to permanent damage.

For an organism to respond to anthropogenic noise, the sound has to exceed that of the ambient noise, which has either non-biological or biological origins. McCauley [Ref 3] noted that non-biological underwater noise has three sources, namely wind (including waves and the surf zone), rain and anthropogenic causes. Wind noise increases with increasing wind speed and most of the noise is generated by bubble oscillations within waves [Ref 4]. Rain produces broad-frequency spectra noise, increasing with the intensity of the downpour.

The most pervasive anthropogenic noise sources are those produced by ships. Shipping sounds cover a wide range of frequencies, and include extremely loud noises when the source is in close proximity. Table 13.2 summarises the non-biological sources of marine noise and provides some expected ranges in relation to the proposed terminal marine facilities.

Underwater biological noises are produced by a wide variety of marine organisms, particularly during reproduction, displays of territoriality and echolocation. Marine invertebrates, for example rock lobster *Panulirus* spp [Ref 3] and snapper shrimp *Alpheus* spp, generally utilise frequency spectra greater than 2kHz. Sounds produced by fish have a wider frequency range, from 100Hz to about 5kHz. Marine mammals demonstrate the greatest range of frequencies during sound production, ranging from 12Hz in large baleen whales such as blue whale *Balaenoptera musculus* to 160kHz in harbour porpoises *Phocoena phocoena* [Ref 4].

Table 13.2 Comparison of Underwater Noise Types (dB[(1)])

SOURCE	FREQUENCY AND STRENGTH
Wind	1Hz - 25 kHz; 95 at 100-200Hz (Force 12)
Rain	Broad spectrum; 80 (heavy rain)
Ships	1Hz - 1kHz; 0 - 200(depending on range)
Invertebrates	2-10kHz; <140
Fish	100Hz - 5kHz; <140
Note: (1) dB – decibels re 1µPa at 1m	

Potential impacts on fish

There appear to be no studies on the reactions of fish to marine construction noise, however there are several studies on fish reaction to seismic activity, which can be used to give an indication of the anticipated impacts. The noise from many marine construction activities is within the same frequency envelope as the noise from the seismic activity.

Behavioural changes became noticeable at about 180dB re1µPa at 1m, and increased with increasing sound intensity. Studies have also demonstrated the ability of fish to acclimatise to airgun noise with time [Ref 5].

The anticipated noise from jetty construction will be related both to vessel noise and the acoustic impact of driving piles.

- Tugs/barges typically generate noise levels in the order of 160 dB at 630 Hz [Ref 6].
- The underwater noise generated by pile driving is typically 130-135 dB re1µPa at 1m, with the strongest signals at approximately 35 and 100 Hz [Ref 6], although levels as high as 246 dB re1µPa at 1m have been recorded.

Both these noise sources are generally below the threshold where behavioural changes are seen in fish, though clearly at very close range (eg a few metres to tens of metres from the piles) fish will be deterred. Even if transient noise levels are significantly higher, this will only serve to make fish avoid the immediate area of marine works for the duration of the actual construction activity. There is considerable evidence to show that fish readily and rapidly return to their former ranges after noisy activities cease, even when the sound pressures are significantly higher eg those associated with seismic shooting [Ref 6]. Overall, impacts to fish due to construction noise will be minor, short-term and localised.

Potential impacts to cetaceans

Cetaceans in general are thought to be fairly tolerant of noise disturbance from marine construction activity and studies have indicated that they readily adapt to changes in noise levels as long as the disturbance is not associated with any activity having a negative effect on them or an apparent threat to them [Ref 4]. There appears to be little available information regarding the effects of noise on dolphins, however studies involving other toothed whales have indicated that disturbance as a result of marine construction has been minimal.

Bottlenose dolphins (*Tursipos truncatus*) reside in many channels used by vessels ranging in size from large tankers to pleasure boats and sport-fishing boats. In Mexico, bottlenose dolphins exposed to frequent boat traffic showed little reaction unless a boat came within 5m [Ref 7]. Sperm Whale (*Physeter macrocaphalus*) reactions to vessel presence are varied,

however, 'startle' reactions have been observed during some attempts to approach sperm whales [Ref 4]. Evidence from the Gulf of Mexico suggests that both pygmy and dwarf sperm whales (*Kogia breviceps* and *K. simus*) orient away from motorised vessels [Ref 4]. There is, however, no clear evidence to suggest that toothed whales have abandoned significant parts of their range because of vessel presence [Ref 4].

There do not appear to be any specific examples of studies undertaken in the Mediterranean, however, it is not anticipated that the noise from construction activity will have any significant effects on cetaceans. If cetaceans are observed within the vicinity of the proposed marine facilities during construction, any vessels will take great care. With the possible exception of an emergency situation, at no time will vessels approach marine mammals at high speed or make rapid changes in course in their vicinity. To this end, a watching brief for cetaceans during construction activities will be in place.

The noise from other marine construction activities is anticipated to have a minor impact only on cetaceans, due to several factors:

- Cetaceans are relatively tolerant of noise at the levels produced by such activities as piling.
- Cetaceans are unlikely to be present in the immediate vicinity of construction activities.
- Cetaceans can easily avoid areas of temporarily high noise levels.

Impacts of underwater noise to seabirds, turtles and seals

The effects of underwater noise on birds and reptiles have not been well studied. Nonetheless, these are highly mobile and wide-ranging animals and it is expected they would avoid areas where noise pressures were excessive. In any event, seabirds would only be subject to underwater noise while actively fishing. This activity is of short duration (relative to roosting and overflight) and any noise exposure will consequently be minor. Since turtles continue to use the wider Iskenderun bay, despite substantial past marine construction activity, it is reasonable to assume that construction noise impacts to turtles will be minor at most.

As the Mediterranean Monk Seal has not been observed within the project area, the potential for noise impacts to this specie is low.

13.6.3 Operational impacts and mitigation

13.6.3.1 General

The potential for ecological impacts from the operation of the marine facilities is relatively limited. The following sources of impact have been identified:

- physical and acoustic impacts associated with tanker traffic;
- the provision of new habitat;
- loss of habitat for turtles through beach erosion;
- impacts of invasive species brought by ballast waters.

Each of these impacts is addressed in the subsections that follow.

13.6.3.2 Impacts of tanker traffic

The typical noise generated by large tankers is in the order of 177dB predominantly around 100Hz [Ref 6], or in the region of 190dB at 25-35Hz [Ref 4]. The latter is at or below the frequency threshold for most fish, and is not likely to have significant impacts [Ref 8]. Loud noises at slightly higher frequencies (the 100-300Hz range) are likely to result in some behavioural change, eg formation of tighter schools and avoidance of the noise source, which is analogous to a normal defence reaction in shoaling fish. Available data suggest that typical avoidance/displacement distances in such situations are in the region of 100-200m [Ref 9].

It should be noted, however, that as the tankers will be stationary for most of the time, the noise generated will be considerably less, thus impacts to fish are expected to be minor. This is supported by the observation that fish frequently shelter under stationary or moored vessels, even if the engines are running. Additionally, tankers on approach to the BTC Marine Terminal jetty will not be running engines at full load, thus the noise levels quoted above will be a significant overestimation.

Research indicates that turtles and marine mammals may react to moving tankers. However, the Gulf of Iskenderun currently has significant amounts of large vessel activity much of it in defined ‘lanes’. It also has smaller fishing boat movements over a wide area. The main threats, other than loss of nesting beaches to turtles, are entanglement in fishing nets, hunting/deliberate killing and choking on marine debris (eg plastic bags). Tanker movements will not add to these threats. The Gulf of Iskenderun does not appear to support any substantial resident or migrating populations of marine mammals. Those that do use the area are probably acclimatised to the current level of marine activities and are unlikely to be further disturbed by tanker movements to and from the BTC Marine Terminal.

Given that the proposed facilities will comprise only two berths, and traffic will be limited to relatively slow moving tankers with approximately 350 to 400 movements per annum, it is expected that operational marine noise will cause only minor impacts to marine turtles and mammals. Further consideration is given to this impact assessment in Section 16, Cumulative Impacts.

13.6.3.3 Provision of new habitat

The jetty piles and rock armour of the causeway will provide a new habitat/substrate for marine organisms. This will have some minor positive ecological impacts in that the different substrata will attract different colonising organisms and add to the overall diversity of what is a fairly impoverished area. Any crevices would provide shelter for grazers and foragers. In addition, sediment may collect in the interstitial spaces encouraging the development of characteristic soft-bottom communities. The jetty structures will also provide shelter from predation for certain species of fish.

13.6.3.4 Loss of habitat through beach erosion

Turtles require low gradient sandy beaches for nesting. The changes in coastal morphology together with the process of longshore drift, has the potential to reduce the nesting resource for turtles locally. However, several factors combine to reduce the scope of such an impact, namely:

- the quantity of beach material intercepted by the jetty footing will be relatively small, thus the knock-on erosion impact to the BOTAŞ beach north of the jetty will be minor;

- the change in sediment budget will be temporary and only last for as long as it takes any accretion around the jetty footing to achieve equilibrium. Thereafter, surplus material will be transported to the BOTAŞ beach as it is currently;

- although two nests were observed on the BOTAŞ beach during the Envy 2001 survey [Ref 2], the relative importance of this beach in the context of the western part of the Gulf of Iskenderun is small. The area to the south of the terminal site between Uzunkelli and Golovasi is of significantly greater value to nesting turtles, where the density of turtle signs was up to 68 per 10km, compared to 20 turtle signs per 10km on the BOTAŞ beach;

- this beach is regularly used as an amenity by personnel from the existing terminal. The disturbance to turtles from regular use of the beach is considered to be much more of a limiting impact that any minor change in sediment.

Although it is not considered that minor changes in beach morphology constitute any significant habitat loss to breeding turtles, the evidence from the turtle surveys undertaken during the summer of 2002 indicates that egg and hatchling predation constitute a significant threat to the reproductive success of sea turtles in this area. As a consequence, it is recommended that measures be introduced to safeguard turtle nesting on the BOTAŞ beach; such measures may include the collection of laid eggs and the establishment of a protected hatchery area within the beach area as well as measures to discourage predators during the period when hatchlings are at risk.

13.6.3.5 Potential introduction of alien species

The introduction of alien species has been a problem in several sea areas around the world, notably the Black Sea, which has experienced significant ecological perturbations due to introduced species such as the planktonic predator *Mnemiopsis leydii* [Ref 10]. The eastern Mediterranean has more diverse and complex marine communities than the Black Sea. This means that ecological niches available for opportunistic colonists are generally fewer than in poorer systems where competition may be less intense. The potential for a catastrophic ecological impact by immigrant species is thus reduced. Of a total of 650 fish species recorded in the Mediterranean, 90 species, representing 56 families are relatively recent arrivals from distant seas. For the past 130 years, the main route of exotic fish species to the Mediterranean has been from the Red Sea through the Suez Canal (termed ‘Lessepsian migration’). The colonisation of Red Sea (Erythrean) fishes has had a major impact on Levantine waters where more than a dozen of these Lessepsian migrants have become important components of commercial fisheries[Ref 14]. Significant lessepsian fish species present in Iskenderun Bay are identified in Section 11.4.3.

The introduction of invasive marine species into new environments by ships’ ballast water, attached to ships’ hulls and via other vectors has been identified as a serious threat to the world’s oceans. Concerns have been voiced at the international level by several organisations including the IMO, GESAMP and CIESM. In response IMO has developed Guidelines for the Control and Management of Ships Ballast Water to Minimise the Transfer of Harmful Aquatic Organisms and Pathogens (Resolution A.868(20)). These Guidelines can be used as a tool, which if correctly applied, will help to minimize the risks associated with ballast water discharge. As scientific and technological advances are made, the Guidelines will be refined to enable the risk to be more adequately addressed. In the interim, the IMO has stated that port States, flag States and other parties that can assist in mitigating this problem should exercise due care and diligence in an effort to conform to the maximum extent possible with the Guidelines.

In recognition of the limitations of the current IMO voluntary guidelines, the current lack of a totally effective solution and the serious threats still posed by invasive marine species, IMO member countries have agreed to develop a mandatory international legal regime to regulate and control ballast water. The IMO's MEPC and its Ballast Water Working Group, are well advanced with developing a new Convention that, it is hoped, will be adopted in 2003. The draft Convention requires ballast water to be sampled and analysed for suspended solids, temperature, salinity, dissolved oxygen and toxic plankton. BTC tankers intending to discharge ballast water will be subject to this law and will require a certificate to discharge ballast at the BTC Marine Terminal. If a Port Authority with responsibility for sampling finds phytotoxins in the ballast water, the ship will be prevented from discharging. As a result, the potential for the introduction of phytotoxins will be minimised, thereby reducing the impact of alien species.

The Gulf of Iskenderun experiences a significant level of international and intercontinental shipping, and has done for decades. The opportunity for colonisation by opportunistic 'aliens' therefore already exists, and will not be significantly changed by the tankers operating from the BTC Marine Terminal, particularly, as many of these vessels will be operating within the Mediterranean basin.

The marine habitats of the project area have thus already been impacted, and will continue to be in the future, regardless of BTC related shipping. Impacts are therefore considered to be minor.

13.7 IMPACTS TO MARINE ARCHAEOLOGY

There are no marine archaeological receptors identified in the vicinity of the proposed BTC Marine Terminal, consequently no archaeological impacts are anticipated. During construction of the jetty, a watching brief will be kept to ensure that appropriate action is taken should any new marine finds be discovered. In the unlikely event of a find, the appropriate authorities will be notified and the find fully documented in accordance with the Cultural Heritage Management Plan (see Appendix C7).

13.8 IMPACTS TO FISHERIES

13.8.1 Introduction

This section identifies potential impacts to fisheries as a result of marine based activities associated with construction and operation of the BTC Marine Terminal. Impacts to commercial fisheries have been identified when an activity is predicted to result in a change to the baseline situation. This section focuses on the predicted changes to fish stocks and fishing activity. Any knock-on effects to livelihoods are discussed in Section 12.

As there are no formal fisheries statistics available for the study area, this assessment has relied, to date, on the reports of local fishermen from Golovasi/Sahil Sitesi, Incirli/Deveciusagi and Haylazi. An additional study, which has collated formal fisheries statistics, has recently been completed. Once the final results have been reviewed, the findings will be used to update the existing mitigation measures such that the impacts to local fishermen are adequately addressed.

13.8.2 Construction and operational impacts and mitigation

The jetty development requires the establishment of an Exclusion Zone and a Manoeuvring Area, enforceable for the full life of the Project (40 years).

The Exclusion Zone (ie that enforced by the coastguard) will be implemented during construction and operation and will be confined to an area 400m on either side of the jetty, ie an area in the order of 208ha.

The Manoeuvring Area around the proposed marine facilities will be approximately 1 nautical mile (1.8km) across, to allow for safe tanker manoeuvring. The size of this zone means that it will overlap with the operational area for the existing jetty to the north, and extend to cover an additional area to the south. In such operating zones, fishing is prohibited by law.

Ecologically, the presence of the exclusion zone and resultant reduced fishing activity in this area may cause an increase in fish numbers during the lifetime of the Project. The use of fishing refugia in promoting recovery of fish populations is receiving increased attention [Ref 11; Ref 12; Ref 13] and the proposed jetty exclusion zone could well act as such. This is anticipated to result in a minor positive impact.

The area in the vicinity of the proposed jetty area is already within a wider operating zone for the Toros Gubre Fertilizer Facility, in which fishing is prohibited by law. Although no formal fisheries statistics for the area are available, consultation with the local fishing community suggests that fishing is carried out in the vicinity of the proposed jetty. Although fish stocks are generally reported to be low in the Gulf of Iskenderun, local communities are reported to rely heavily on fishing as a source of income. It has been noted that shrimp (*karides*) fishing is important locally, having a higher market value than other fish. Due to the uncertainties associated with the information sources, the scale of the impacts to fishermen is unknown. Any negative impacts associated with the loss of fishing grounds, are however, likely to be confined to fishermen from the nearby settlements of Golovasi and the associated hamlet of Sahil Sitesi who are known to fish in the area. Section 12 discusses the likely implications for livelihoods. In the absence of any formal data, the available information suggests that fishing activity in the area is likely to be low to moderate, despite the existence of the wider exclusion zone.

Given the beneficial effects to fish biology (and fish stocks) that will result from the presence of the exclusion zone, overall impacts to fishermen will be mainly influenced by physical constraints on fishing efforts as opposed to the actual availability of fish (see Section 12 for a fuller discussion).

13.9 IMPACTS TO NAVIGATION AND SHIPPING

13.9.1 Introduction

This section identifies potential impacts to shipping and navigation in the Gulf of Iskenderun. Impacts to shipping and navigation have been defined when an activity is predicted to result in a change to the baseline situation. In the absence of significance criteria, the significance of an impact has been determined through professional judgement.

13.9.2 Construction impacts and mitigation

Construction vessel activity will be confined to the immediate vicinity of the BTC Jetty, other than during mobilisation and demobilisation. This area is not frequented by other vessels, other than tankers *en route* to/from the existing BOTAŞ Marine Terminal facilities, which, due to the presence of a wider exclusion zone, are under the direction of pilots.

It is not anticipated that vessels deployed during construction will affect other navigational interests in the Gulf of Iskenderun. Interaction between vessels at sea and rights of passage

are governed by international maritime regulations and protocols, which are generally adhered to by officers and crew of commercial maritime traffic, who will be familiar with them. As such, impacts from construction vessels are considered to be minor.

13.9.3 Operational impacts and mitigation

13.9.3.1 Exclusion zones

The limited aerial extent of the Exclusion Zone is such that it will not interfere with other navigation in the Gulf of Iskenderun. The wider manoeuvring area of 936ha (9.36km^2) may require some vessels en route to the Toros Gubre Fertiliser Facility to approach from a slightly more seaward direction, but given the presence of an exclusion zone around the existing BOTAŞ facility, any additional re-routing is not considered significant. The exclusion and operating zones will be clearly marked on future nautical charts, and notices to mariners will be posted as appropriate in the interim.

Local *bona fide* navigation associated with the fishing fleet from the settlement of Sahil Sitesi (Golovasi) will not be affected.

13.9.3.2 Tanker traffic

Tanker traffic associated with the operational terminal will follow the existing shipping lanes, and will only comprise an incremental change to the existing pattern of shipping. Within the Ceyhan port area, pilots will be used to guide vessels to ensure safe transit.

Given the existing level of commercial traffic in the Gulf of Iskenderun (eg that associated with existing terminals, the Toros Gubre Fertiliser Facility and industries around Iskenderun itself), tanker traffic is likely to represent a minor impact to the current maritime navigation regime. It is recommended that a shipping risk study be undertaken prior to operation in order to predict cumulative impacts and design appropriate procedures for the long term management of tanker traffic in the vicinity.

13.10 IMPACTS TO TOURISM AND RECREATION

13.10.1 Introduction

Construction and operation of the BTC Marine Terminal site and proposed marine facilities has the potential to cause impacts to recreation and tourism. Impacts have been defined when an activity is predicted to result in a change to the baseline situation. The significance of impacts to tourism and recreation is often difficult to determine and is quite subjective in nature. In the absence of significance criteria, the significance of an impact has been determined through a combination of consultation with local stakeholders that might be affected and professional judgement.

13.10.2 Construction and operational impacts and mitigation

Tourism is not an existing major source of income in the project area. Existing tourism and recreational facilities in the project area are largely confined to tourist facilities at the settlements of Incirli, Golovasi, Sahil Sitesi and the BOTAŞ recreational facilities.

Factors, which may affect the area's suitability as a tourist site, are the visual impacts of the existing BOTAŞ Marine Terminal, tanker traffic and increased industrialisation in the wider project area. The proposed BTC Marine Terminal will result in incremental visual impacts,

increased tanker traffic and minor noise impacts (construction phase only), however it will not change the overall character of the area.

It is possible that there may be some decline in regional visitors to the area as a result of the reduced tourism and recreational appeal, however these impacts are anticipated to be minor at most.

The potential for impacts to livelihoods associated with tourist activities is discussed in Section 12 of this report.

14 MARINE TERMINAL - ACCIDENTAL EVENTS AND INCIDENTS

14.1 INTRODUCTION

A description of the facilities and anticipated operational activities associated with the BTC Marine Terminal is presented in Section 9. The assessment of terrestrial and marine baseline environmental conditions at (and in the vicinity of) the Terminal are presented in Sections 10 and 11 respectively, while potential impacts and measures for their mitigation under normal operating conditions are provided in Sections 12 and 13. This section of the EIA Report addresses potential accidental events, which could lead to a spill of oil and consequential environmental damage.

This section of the Report addresses the accidental oil spill events associated with the Proposed BTC Marine Terminal, their likelihood of occurrence, the principal environmental sensitivities in the vicinity, and contingency measures that will be put in place to avoid any impact. It specifically excludes the assessment of accidental events arising from operation of the pipeline or the associated AGIs, which are covered in Section 8.

The underlying principles of environmental risk assessment (ERA) are described fully in Section 8.3 (with reference to the BTC Pipeline and associated facilities) and the discussion is not repeated here, other than to emphasise that for the purposes of this assessment, environmental risk may be defined as follows.

Environmental Risk = Frequency of Failure Event x Consequences of Event (which relates to Volume of oil spilled and Environmental Sensitivity)

The ERA has followed a similar broad approach to that adopted for determination of environmental risk of the Pipeline AGIs in Section 8.8. However, because of the more extensive nature of the facilities, higher intensity of oil movements and greater sensitivity of the (marine) environment, a significantly more wide ranging assessment is appropriate for assessment of accidental events associated with operation of the BTC Marine Terminal.

The assessment has focused on three aspects of BTC Marine Terminal operations:

- risks associated with accidental events within the terminal complex leading to oil spills that impact the terrestrial environment only;
- risks associated with accidental events both on-shore and offshore that impact the marine and coastal environment (principally within the Gulf of Iskenderun);
- trans-boundary consequences of shipping accidents at sea.

14.2 TERRESTRIAL SPILLS

14.2.1 Initiating events

14.2.1.1 Overall approach to assessment of risks

The approach adopted for the assessment of risk posed by the Pipeline and associated AGIs has been presented in Section 8. A similar approach has been adopted for the assessment of environmental risks posed by activities associated with operation and export of oil from the BTC Marine Terminal.

A Quantitative Risk Assessment (QRA) has been undertaken of the BTC Marine Terminal, which has identified various scenarios relating to the accidental release of oil from the proposed Terminal facilities. As a first step, the main hazards associated with the BTC Marine Terminal facilities have been identified. These included the following equipment installations:

- the storage area with seven crude oil floating roof tanks;
- two 42" gravity fed ship loading pipelines;
- scraper receiving station and relief tank.

A detailed assessment of the likely frequency of release of crude oil from these facilities was then carried out. The following modes of release were considered:

- releases from crude storage tanks and scraper receiving station;
- releases from ship loading pipelines.

A consequence assessment to determine associated release quantities was then carried out and this, combined with the frequency of spills, was used to determine the overall level of risk of a spill event.

By including a consideration of the key receptors of potential spill scenarios, the conventional assessment of the risk of a spill event (ie size of spill versus frequency) has been extended to ascertain the risk to the environment. The result of this is a more complete understanding of the likelihood and consequences of spills, which will feed into the development of the Oil Spill Response Plan (OSRP, an outline of which is presented in Appendix C6). It is intended that the OSRP will address the full range of identified scenarios and develop strategies to mitigate the potential hazardous outcomes.

14.2.1.2 Assessment of terrestrial hazards

The hazards identified in the ERA have been assessed in a HAZOP study and essentially relate to a release of oil to the environment. The failure mode or initiating event that may result in a release, the cause of the initiating event and related control and mitigation actions are detailed in Table 14.1 and Table 14.2. Control actions relate to actions that limit the frequency of occurrence of the failure mode. Mitigation actions relate to actions that limit the potential hazardous impact in the event that failure mode does occur.

Table 14.1 Crude Oil Storage Failure Modes and Associated Actions

Failure Mode	Cause	Control and Mitigation Actions
Tank overfilling:	Human error	Status of tank valves, as well as levels is monitored by SCADA system.
	Faulty level indication	Tank management system is backed-up by independent LSHH which closes the inlet valve.
Tank Leak:	Corrosion	Internal coating will be in place for lower shell course and tank bottom. Cathodic protection system provided. Leak detection system will be in place in tank foundation. Daily tank external inspections and annual internal inspections.
	External loading/impact	Wind, rain, seismic loadings are taken into consideration in accordance with the standards. Thermal loading of pipe connections is also considered.
	Defect in wall and/or bottom	Tests will be carried out during construction, as well as hydrotest as required by the standards.
	Gasket/flange/valve leak in bunded area	All areas where leakage could occur are protected by a bund or catchment pit. Operator inspections shall detect such minor leaks.
	Poor QC inspection	Appropriate requirements are defined in the specifications. Construction shall be monitored by nominated Employer's Representative and Third Party Inspectors as required.
Catastrophic tank rupture:	Corrosion	Corrosion control as appropriate.
	External events (earthquake)	Seismic loading is included in the design.
	Fire	Fire fighting systems (cooling water, rim foam, external water and foam hydrants) will be in place in accordance with the required standards. Twofire tenders will be provided. Fire station is permanently manned. Fire detection system is provided.
	Flame impingement	Cooling rings are provided for tanks.
Bund failure:	Overtopping of bund by surge of liquid	Bund is sized for 110% of tank capacity in accordance with the required standards.
	Structural failure of bund wall due to impact of liquid	Bund wall has been designed in accordance with the relevant standards.
	Over flow of bund wall by retained fire water	Single tank bund capacity is 165,000 m^3, fire fighting reservoir capacity is 6,800 m^3.
General hazards:	Drain valves left open	Main process drain valves are connected to the closed drain system. Closed drain tank has LAH and LAHH. Tank drain valves are routed to drain pits within the respective bunds; each drain pit has a LAH alarm.

Failure Mode	Cause	Control and Mitigation Actions
	Holes in the bund wall	Monitoring by operators. Internal bund wall has appropriate lining, pipe penetrations have special sealing arrangements.
	Failure of two or more tanks in a common bund	Each main storage tank has its own bund.
	Rocketing of tanks carrying associated burning liquid.	Separation distances between tanks and other facilities are in accordance with standard practice.
	Vandalism/sabotage	Main tank farm is within its own security fenced area, which is respectively located within the existing BOTAŞ security fenced area.

Table 14.2 Ship Loading Pipelines Failure Modes and Associated Actions

Failure Mode	Cause	Control and Mitigation Actions
Leak in ship loading pipeline:	Corrosion/erosion	Buried pipeline has external coating and cathodic protection system. Leak detection system is also provided. Flow velocities are below the erosion velocity.
	External loading/impact	Pipeline is buried with min 0.8m cover up to jetty and along jetty is separated from the main causeway.
	Defective pipe	Pipe is factory tested and will also be subject to field NDT and hydrotest.
	Gasket/flange/valve leak	The pipe and associated valves are generally fully welded. All areas where leakage could occur (such as flanged connections) are protected by a bund or catchment pit.
	Surge	Surge study has been carried out and appropriate overpressure protection facilities will be in place.
	Inadequate QA/QC controls/inspection	Appropriate requirements are defined in the specifications. Construction shall be monitored by nominated Employer's Representative and Third Party Inspectors as required.
	Materials/construction defect	Appropriate NDT and inspection requirements have been specified.
Rupture of ships loading pipeline:	External loading/impact	Jetty is designed for impact of 0.2 m/s
	Overpressure and surge	Surge study has been carried out and appropriate overpressure protection facilities will be in place.

Failure Mode	Cause	Control and Mitigation Actions
	Natural hazards	Geohazard study has been carried out and appropriate design factors incorporated. Other environmental conditions (eg wave height, wind, etc.) have been investigated and appropriate design factors incorporated.
	Inadequate QA/QC controls/inspection	Appropriate requirements are defined in the specifications. Construction shall be monitored by nominated Employer's Representative and Third Party Inspectors as required.
	Materials/construction defect	Appropriate NDT and inspection requirements have been specified.

The above tables demonstrate the extent to which design measures have been implemented to minimise risk to both the terrestrial and marine environments.

14.2.2 Frequencies of failures and consequences of spills to land

For land releases, the maximum spill into the local environment is catastrophic rupture of a storage tank with subsequent bund overtopping. This could lead to the release of up to 12,600te oil, but such an event is rare. It is calculated that the return period for such an event is in the order of 100,000 years [Ref 10; Ref 11].

Bund walls are not designed to contain catastrophic failures, but unless the bund wall is built significantly higher, theoretically it will not fully contain all the oil if the stock tank unzips. It is concluded however, due to the remoteness of the event increasing the height of the bund is not justified. Table 14.3 shows the frequency of release of various spill sizes resulting from the rupture of storage tanks based on the maximum head from the storage tanks to the onshore pipeline.

Table 14.3 Spill Sizes vs Frequency of Releases from Storage Tanks

Release	Amount spilt (tonnes)	Frequency (per year)	Impact
50mm leak	2300	6×10^{-4}	Release in bund
Rupture into bund	126000	4×10^{-5}	Release in bund
Rupture and overtop	12600	1×10^{-5}	Release outside bund

A rupture of the pipeline connecting the terminal to the jetty would also give rise to a catastrophic release into the local environment. The release rates of the spills from the ship loading pipelines have been modelled using the BP Cirrus software (version 6.1, 2000). The release rates for the various hole sizes are given in Table 14.4 based on the maximum head from the storage tanks to the onshore metering (120m head).

Table 14.4 Release Rates for Ship Loading Pipeline

Hole size (mm)	Release rates (kg/s)
25	2.9
50	12
100	47
Full bore rupture	5000

The frequency of spills from the ship loading pipeline have been determined and Table 14.5 shows the frequency of spills along with the corresponding spill quantities.

Table 14.5 Spill Sizes vs Frequency from Ship Loading Pipelines

Hole size (mm)	Amount spilt (tonnes)	Frequency per year
25	21	6.5×10^{-4}
50	45	3.7×10^{-4}
100	90	3.1×10^{-4}
Full bore rupture	2600	2.2×10^{-5}

There are standard codes of practice for such pipelines and it is judged that adherence to such codes would ensure that the risk is as low as reasonably practicable (ALARP) as the frequency of a major pipeline failure is again remote.

14.2.3 Accounting for geohazards

The ERA has included a quantitative assessment of the possible geohazards at the proposed BTC Marine Terminal. During this study hazards and associated actions to mitigate these hazards have been identified (see Table 14.6).

The main geohazard identified is a seismic event due to the Karasu, Yumurtalik and Karatas Faults.

Table 14.6 Geological Failure Modes

Failure Mode	Threats	Controls / Action Taken in Design
Earthquakes: Terminal is in area of seismic activity and with fault lines	Tank and equipment failure leading to potential fire and fatalities	Engineering design considerations include: • strengthening tank bases and bunding to withstand lateral and vertical movement; • utilising uprated pipe flanges and pipe thickness; • automated flow control valves which close within 5 seconds to reduce loss due to pipe or tank failure.
Erosion/ subsidence	Tank and equipment failure leading to potential fire and fatalities	Taken into consideration in design. No history of ground slide etc in 25 years of operation of current terminal.

14.2.4 Accounting for seismic events

A methodical approach has been followed to determine the frequency of earthquake events that exceed the Safe Shutdown Earthquake (SSE) that could result in failure of plant and piping and give rise to a release of oil to the terrestrial environment. Based on these earthquake frequencies, Table 14.7 summarises the spill sizes for those events that exceed the SSE. It is assumed that during a severe earthquake the bund may not maintain its structural integrity and therefore any release has the potential to impact the surrounding area.

Table 14.7 Spill Sizes vs Frequency of Releases for Seismic Events

Hazard Source	Release Size	Modified Mercalli Intensity	Frequency (per year)	Spill amount (tonnes)
Crude Storage Tanks	50mm	VIII	2×10^{-5}	2300
		IX	5×10^{-5}	2300
		X	6×10^{-6}	2300
	Rupture in Bund	X	4×10^{-6}	126000
		XI	5×10^{-6}	126000
	Rupture overtops Bund	X	4×10^{-6}	12600
		XI	5×10^{-6}	12600
Pipelines	50mm	VIII	2×10^{-5}	150
		IX	5×10^{-5}	150
		X	6×10^{-6}	150
	Full Bore	X	4×10^{-6}	3000
		XI	5×10^{-6}	3000

Box 14.1 shows the comparison between the earthquake magnitude (Richter Scale) and the intensity scale (Mercalli). The Mercalli scale is considered to provide a more meaningful measure to the non-scientist as it refers to effects that are actually experienced.

Box 14.1 Magnitude/Intensity Comparison

Magnitude	Intensity	Description
1.0 - 3.0	I	**I:** Not felt except by a very few under especially favourable conditions.
3.0 - 3.9	II - III	**II:** Felt only by a few persons at rest, especially on upper floors of buildings. **III:** Felt quite noticeably by persons indoors, especially on upper floors of buildings. Many people do not recognise it as an earthquake. Standing motor cars may rock slightly. Vibrations similar to the passing of a truck. Duration estimated.
4.0 – 4.9	IV – V	**IV:** Felt indoors by many, outdoors by few during the day. At night, some awakened. Dishes, windows, doors disturbed; walls make cracking sound. Sensation like heavy truck striking building. Standing motor cars rocked noticeably. **V:** Felt by nearly everyone; many awakened. Some dishes, windows broken. Unstable objects overturned. Pendulum clocks may stop.
5.0 – 5.9	VI – VII	**VI:** Felt by all, many frightened. Some heavy furniture moved; a few instances of fallen plaster. Damage slight. **VII:** Damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable damage in poorly built or badly designed structures; some chimneys broken.
6.0 – 6.9	VII – IX	**VII:** Damage slight in specially designed structures; considerable damage in ordinary substantial buildings with partial collapse. Damage great in poorly built structures. Fall of chimneys, factory stacks, columns, monuments, walls. Heavy furniture overturned. **IX:** Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb. Damage great in substantial buildings, with partial collapse. Buildings shifted off foundations.
7.0 and higher	VIII or higher	**X:** Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations. Rails bent. **XI:** Few, if any (masonry) structures remain standing. Bridges destroyed. Rails bent greatly. **XII:** Damage total. Lines of sight and level are distorted. Objects thrown into the air.

14.2.5 Overall frequency and spill size of release

The impact of release on land will depend on whether a release is within a bunded area or not. The majority of releases from tanks will be contained within the bunds. However, in the event of a catastrophic failure, some liquid may overtop the bunds due to the momentum of the release. Such a phenomenon has occurred in the past, although this has generally been over low height earth dykes with sloping sides. Pipeline releases are all assumed to occur outside the bunded area, although there are small sections within the bunds.

The frequencies of releases to land are given in Table 14.8 and are illustrated in Figure 14.1 and Figure 14.2 respectively, which show the cumulative frequency against spill size.

Table 14.8 Summary of Releases on Land

Hazard Source	Release Size	Frequency (per year)	Spill amount (tonnes)
Crude Storage Tanks (bunded)	50mm	6.8×10^{-4}	2300
	Rupture in Bund	4.9×10^{-5}	126000
	Rupture overtops Bund	1.9×10^{-5}	12600
Pipelines	25mm	3.2×10^{-4}	21
	50mm	2.6×10^{-4}	45
	100mm	1.5×10^{-4}	94
	Full Bore	2.0×10^{-5}	2600
Oil Reception	25mm	1.1×10^{-3}	31
	50mm	8.4×10^{-4}	70
	100mm	3.5×10^{-4}	180
	Full Bore	2.4×10^{-4}	620
Metering	25mm	2.6×10^{-2}	4
	50mm	7.1×10^{-3}	10
	100mm	2.2×10^{-3}	24
	Full Bore	8.8×10^{-4}	350

14.2.6 Environmental Receptors for Terrestrial Spills

The above sections have identified the hazards and risks associated with the onshore facilities at the BTC Marine Terminal. In order to understand the potential consequences of accidental events, these are summarised below along with the potential receptors for each event.

The limited environmental sensitivities within and adjacent to the terminal site (as discussed in Section 10) serve to reduce the scope of potential accidental impacts. Critically, there are no permanent surface water features, other than the sea or sensitive ecological habitats at risk from a terrestrial spill. The key sensitivities can therefore be summarised as follows (see Table 14.9):

- agricultural land is present within the site boundary and immediately adjacent to it.
- the afforested area of BOTAŞ is located in the vicinity of the tank farm site.
- a corral for a small herd of goitred gazelle is located near the existing general facilities area.
- an unconfined aquifer lies approximately 1.2km to the west of the site. There are, however, a series of ephemeral channels within 500m that will connect to the aquifer.

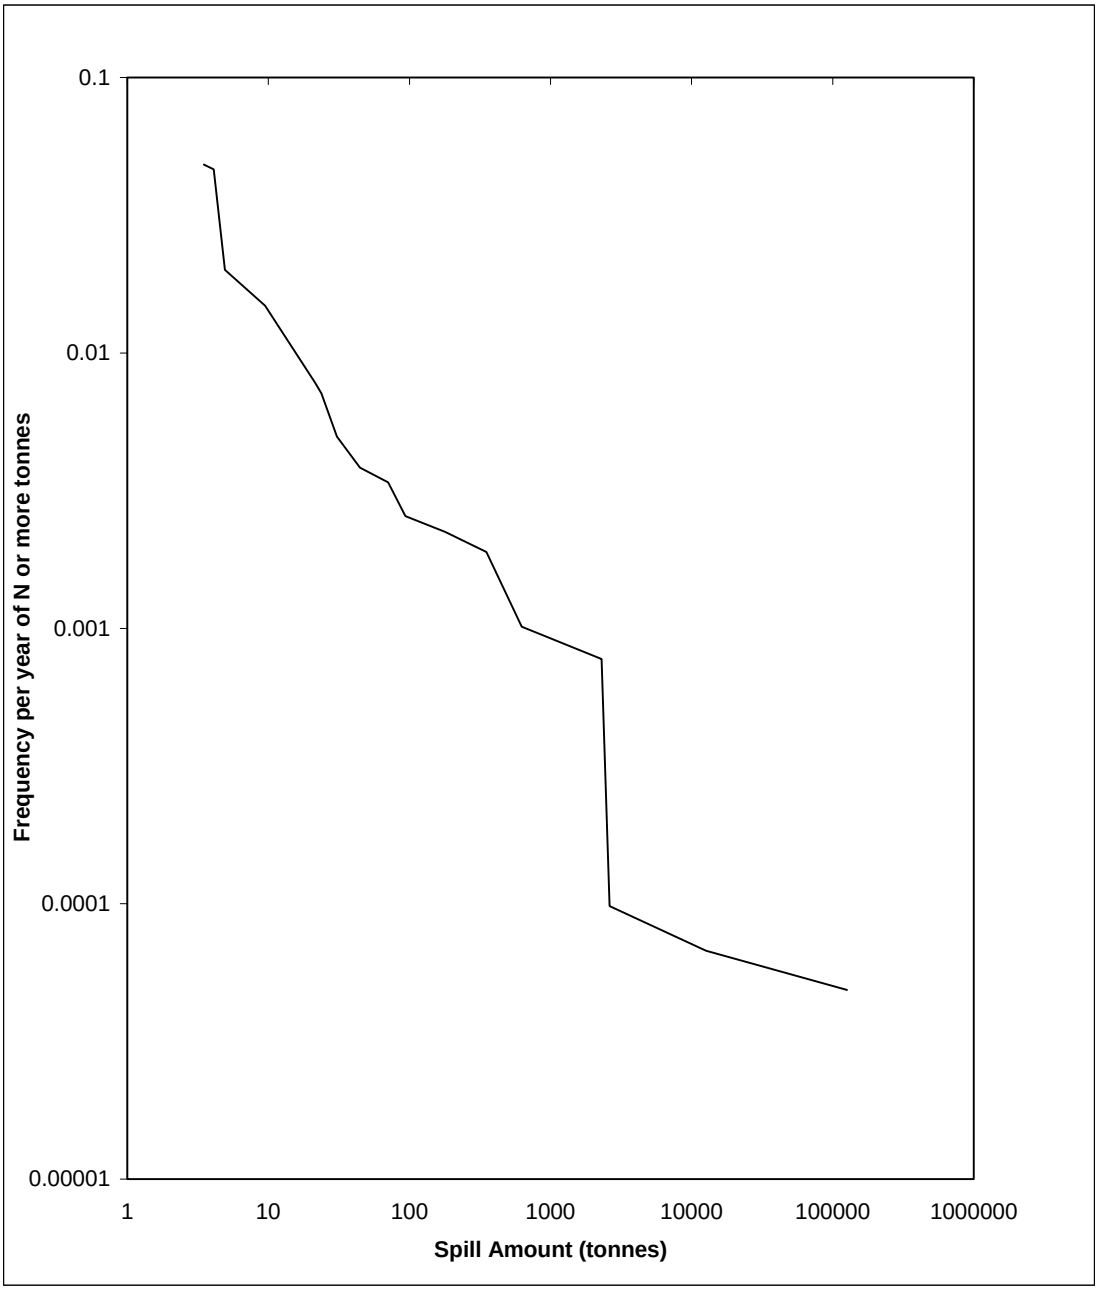

Figure 14.1 Cumulative Frequency vs Spill Size for Releases on Land (including releases into Bund)

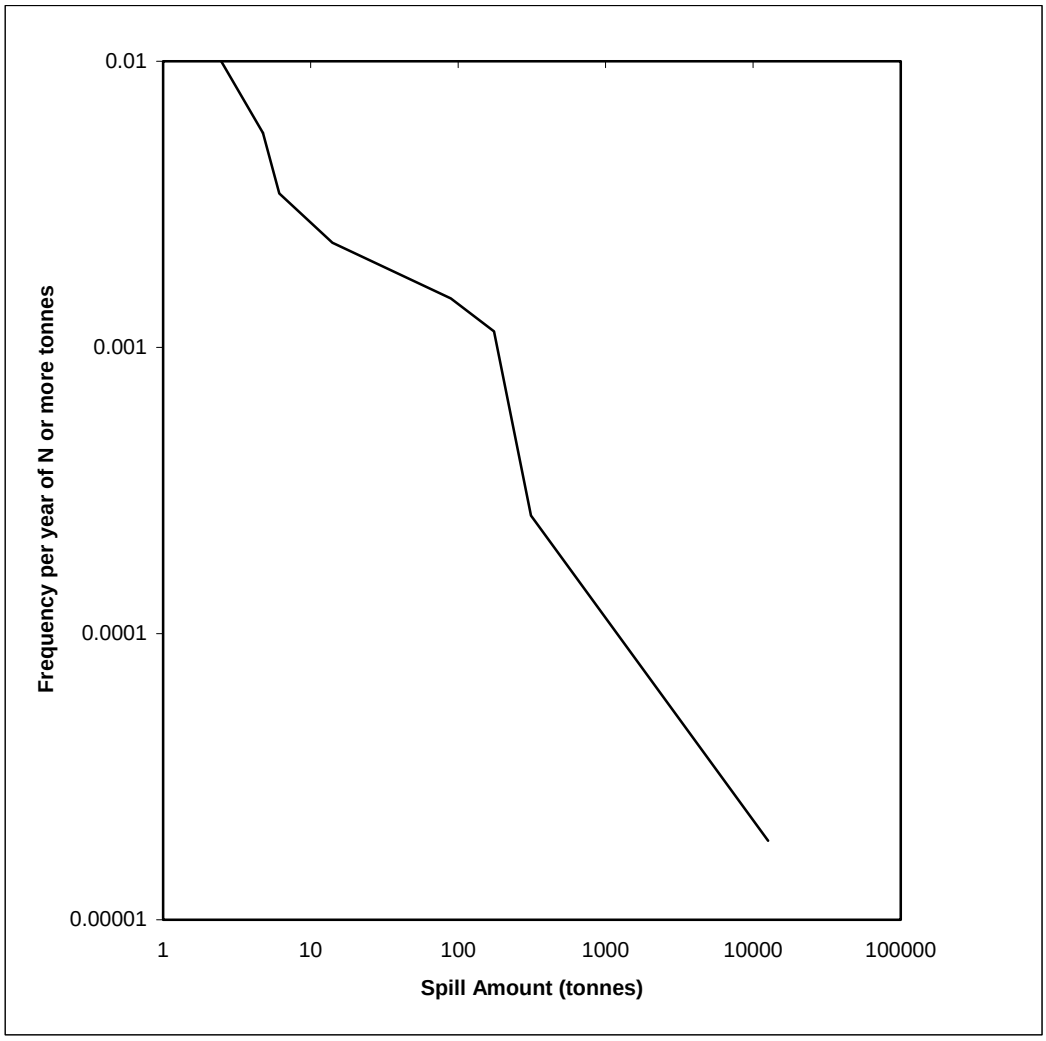

Figure 14.2 Cumulative Frequency vs Spill Size for Releases on Land (releases outside bund)

Table 14.9 : Environmental Sensitivities to Terrestrial Spills

Source	Spill Size (te)	Frequency	Main Receptor	Sensitivity	Comment
Storage Tanks					
50mm leak into bund	2300	6.8×10^{-4}	bund area	not sensitive	Engineered bund designed to contain spills.
rupture in to the bund	126000	4.9×10^{-5}	bund area	not sensitive	Large spill volume mostly contained in bund.
rupture overtops bund	12600	1.9×10^{-5}	land downhill from tank	Highly sensitive	The land, which is exposed to flooding, may be used for agriculture or an afforestation site. Spill may enter ephemeral watercourses. No perceived threat to dwellings.
Oil Reception, Loading Line, Oil Metering					
25mm leak	4-31	2.8×10^{-2}	land in vicinity of leak	Potentially sensitive	Small volume of release is thus unlikely to have an extensive impact.
50mm leak	10-70	8.4×10^{-3}	land in vicinity of leak	Potentially sensitive	Moderate release volume. Potential to impact sensitive receptor if leak is in or near an agricultural area.
100mm leak	24-180	2.8×10^{-3}	land in vicinity of leak	Potentially sensitive	Moderate release volume. Potential to impact sensitive receptor if leak is in or near an agricultural area or at western edge of site, where groundwater is at risk.
full bore rupture	350-2600	1.1×10^{-3}	wider area	Potentially sensitive	Exceptionally rare event. Potential to impact surrounding agricultural areas, unconfined aquifer and ephemeral watercourses.

14.3 SPILLS IMPACTING MARINE/COASTAL ENVIRONMENT

An ERA of oil spills impacting the marine/coastal environment has been undertaken by DNV. The DNV Summary Report is presented below in its entirety, subject only to reformatting to fit into the structure of this EIA Report.

DNV has, on commission from BOTAŞ Petroleum Pipeline Corporation, performed an environmental risk assessment (ERA) for the planned BTC Marine Terminal (DNV report no. 2002-0396). The following section is an extraction of this risk assessment.

The risk assessment comprises the following elements:

- Technical risk assessment (TRA) with quantification of the frequency of accidental oil spill to the marine environment. The TRA is limited to the tank farm, the transport pipelines from the tank farm to the jetty, the jetty, the loading arm and to accidental events with the transport vessels within the operational zone of the terminal. The TRA will not comprise accidental events in the ship lane.

- Oil drift modelling based on scenarios defined in the TRA.

- Description of environmental conditions relevant for the risk assessment and establishment of Valuable Ecosystem Components (VEC), which will act as risk indicators.

- Assessment of consequences of the VEC, based on the results of the oil drift modelling and effects of oil on the actual VEC.

- Assessment of risk as a combination of frequency of an oil spill and its consequences to the VEC.

14.3.1 Description of accidental release scenario

Section 4 in DNV Report No. 2002-0396 presents the assessment of accidental release scenarios, which forms the basis for the ERA.

An **accidental release scenario** is defined as:

> *"an accidental event where the consequence is release of oil to the sea. The frequency of this event has been assessed together with the estimated consequence in terms of amount of oil spilled (given as an oil release rate combined with a release duration)."*

The accidental release scenarios for the BTC Marine Terminal have been defined by carrying out a technical risk assessment (TRA), by applying the methodology described in Table 14.10. In general, it has been sought to reflect the local operational and technical conditions at the terminal when assessing the accidental release scenarios. The assessment has been carried out based on information from technical drawings, maps, reports and direct communication with the staff projecting the terminal. All assumptions made in the TRA are considered to be on the conservative side.

Table 14.10 Methodology for TRA

ACTIVITY	DESCRIPTION
Hazard identification	The purpose of this task is to identify all potential accidental events (hazards), which may cause release of oil to the sea in the terminal area.
Frequency assessment	The expected average occurrence frequencies per year for events identified in the Hazard identification are assessed based on a combination of theoretical models and statistical data.
Consequence assessment	By estimating the potential amount of oil released to the sea, the consequence of each hazard is assessed. Both release rate and release duration are estimated by applying simplified theoretical models, seeking to reflect the actual technical and operational conditions at the terminal.
Risk assessment	The risk of each hazard is expressed by the *accidental release scenarios*, which, as already stated above, are defined as the product of the frequency of each hazard and its consequence.

14.3.1.1 System definition and main assumptions

The systems analysed in the TRA comprise:

- seven onshore atmospheric storage tanks, each with a storage capacity of 126 000 tonnes of crude oil;
- two ship loading pipelines (42’’), each 6.1km long, transferring the oil from the storage tanks to the export tankers at the jetty. The transfer of crude oil is purely gravity driven;
- one jetty with two berths, each berth can receive an export tanker with loading capacity between 80 000 – 300 000 dwt. Loading may take place at both berths simultaneously;
- ship activity within the BTC Marine Terminal harbour restriction zone. Tanker activity data is specified in Table 14.11.

Table 14.11 Tanker activity data

Tanker size (kbbls)*	Tanker size (dwt)**	Proportion of total number of tankers (assumed)	Average loading time per loading operation (hours)	Number of visits per year
500	70 000	10%	16	70
1000	140 000	70%	25	245
2000	280 000	20%	40	35
Total	-	-	-	350

**kbbls = kilo barrels
*dwt = dead weight tons; 1 ton = 7,3 bbls
Based on the data in Table 14.12, the total number of hours vessels loading at the new jetty will be 8645 hours per year.

Assumptions applied for the risk assessment:

- Three loading arms per tanker are always used during loading operations (independent of ship size).

- Total loading rate per berth = 9540m^3/hour (independent of ship size).
- ESD (emergency shut-down) within 15s, and ERS (emergency release system) is activated within 5s. The particulars regarding these systems are described in the control and operating philosophy document.
- Disk Valves (as part of the ERS system) are not assumed to resist surge pressure in case of activation of ERS before ESD is completed.
- The pipelines are assumed to be filled with oil 100% of the time
- The pressure in the loading lines at the jetty is about 12 barg.
- On average there is always one ship loading at the jetty (ref. 8645 loading hours per year/8760 hours = 0,99).
- The BOTAŞ port regulations and the offshore control and operating philosophy form the basis for the assessment of risk related to overloading of cargo tanks.
- The storage capacity of one cargo tank is typically 10 000 tonnes.
- 67% of the export tankers have single hull.
- On average the loading tankers at the jetty are half filled, and so is each cargo tank.
- The storage capacity of a fuel oil tank is typically 2000 tonnes. The fuel tanks are assumed always to be located in wing tanks, and also to always be full.
- The cargo tank area is assumed to be 75% of the ship length, and fuel oil tanks are assumed to be 5% of the ship length.

14.3.1.2 Release to the sea from loading arms

Table 14.12 presents the basis frequencies for oil release to the sea from loading arms. The frequencies are related to loading operation of product tankers, a study performed by DNV for the UK Health and Safety Executive in 1990, but are considered to be valid for crude oil tankers as well.

Table 14.12 Release from loading arms, basis frequencies

#	Failure mode	Frequency per loading operation	Release size distribution		
			small	medium	large
A	Release from loading arm	5.10E-05	0.8	0.19	0.01
B	Loading arm quick disconnection failure	5.10E-06	0	0	1
C	Failure in vessel piping or pumping system	7.20E-06	0.8	0.19	0.01
D	Human failure	7.20E-06	0.8	0.19	0.01
E	Mooring failure	3.80E-06	0	0	1
F	Overfilling of cargo tank	1.20E-04	0.8	0.19	0.01
	Total	1.94E-04			

The failure frequencies are assumed to include oil releases caused by the following events:

- Release due to surge pressure caused by activation of ERS before ESD is completed,
- Excursion of loading tanker due to earthquake/tsunamis, heavy swell and/or mooring failure, impact from other ship.

Given that there are 350 loading operations per year, the release frequencies related to loading arm operations are given in Table 14.13.

Table 14.13 Loading arm releases - frequency of oil spill to sea per year distributed on release size

#	Failure mode	Frequency per year	Release size distribution		
			small	medium	large
A	Release from loading arm	1.79E-02	1.43E-02	3.39E-03	1.79E-04
B	Loading arm quick disconnection failure	1.79E-03	0	0	1.79E-03
C	Failure in vessel piping or pumping system	0	0	0	0
D	Human failure	2.52E-03	2.02E-03	4.79E-04	2.52E-05
E	Mooring failure	1.33E-03	0	0	1.33E-03
F	Overfilling of cargo tank*	4.20E-04	0	0	4.20E-04
	Total	2.39E-02	1.63E-02	3.87E-03	3.74E-03

*** overfilling of cargo tanks is treated as a separate hazard (see Section 14.3.1.4)**

The release rates will depend on pressure and damage size. For the TRA a minor and a large release scenario have been defined (see Table 14.14):

Table 14.14 Release rates and duration – loading arms

Scenario	Release rate, prior to shut-down	Average release rate during shut-down	Detection time	Shut-down time	Total release to sea (tonnes)*
Minor	1 kg/s	1 kg/s	4 hours	15 seconds	14
Large	2250 kg/s	2250/2 = 1125 kg/s	0 – 60 seconds	15 – 60 seconds	17 - 200

***release of loading arm content after shut-down of cargo transfer is not included.**

The risk for oil spill to the sea from loading arms is summarised in Table 14.15**.**

Table 14.15 Loading arm release risk – accidental release scenarios

Failure mode	Frequency per year	Release size distribution	
		Minor*	Large*
Release from loading arm	1.79E-02	1.43E-02	3.57E-03
Loading arm quick disconnection failure	1.79E-03	0	1.79E-03
Failure in vessel piping or pumping system	0.00E+00	0	0
Human failure	2.52E-03	2.02E-03	5.04E-04
Mooring failure	1.33E-03	0	1.33E-03
Total	2.35E-02	1.63E-02	7.19E-03

***Release rates and duration as specified in Table 14.14.**

14.3.1.3 Release to the sea from ship loading pipelines

The frequency assessment of accidental cargo releases from the ship loading lines has been based on failure frequencies used in several former risk assessments performed by DNV, see Table 14.16. The failure data has, however, been adjusted to reflect the relatively high seismic activity in the area.

Table 14.16 Failure frequencies (per km.year) for ship loading pipeline – distribution on failure mode and damage size*

Damage size / Failure Mode	Small	25mm	50mm	100mm	Rupture	Total	Contribution
Defects	3.60E-05	1.20E-05	6.00E-06	6.00E-06		6.00E-05	22 %
Operational	8.20E-06	2.70E-06	1.40E-06	1.40E-06		1.37E-05	5 %
External Corrosion	2.60E-05	7.30E-06	3.60E-06			3.69E-05	14 %
Internal Corrosion	1.80E-05	5.20E-06	2.60E-06			2.58E-05	10 %
Natural Hazards	5.70E-05	1.90E-05	9.50E-06	9.50E-06		9.50E-05	36 %
External Impact	1.10E-05	7.10E-06	7.10E-06	8.80E-06	1.80E-06	3.58E-05	13 %
Total	1.56E-04	5.33E-05	3.02E-05	2.57E-05	1.80E-06	2.67E-04	100 %

***Damage size is given as hole diameter, damage assumed to be circular**

Table 14.17 and is found as; failure frequency per km year multiplied by sea exposing pipeline[1] length multiplied by 2 (because of two pipelines). Large damages (100mm and rupture) due to natural hazards and external impact are expected to affect both pipelines in the same event and the frequency is not multiplied by two. The sea exposing pipeline length for a minor release is equal to the offshore part of pipeline, 2.5km. While for a large release it comprises the offshore part of pipeline and 20% of onshore part of pipeline, 3.2km.

[1] The "sea exposing pipeline" is defined as that length of terrestrial pipeline between the storage tanks and the loading jetty. Any spill from this section is deemed to potentially impact on the sea.

Table 14.17 Failure frequencies (per year) for ship loading pipelines – distribution on failure mode and damage size*

Damage size / Failure Mode	Small	25mm	50mm	100mm	Rupture	Total	Contribution
Defects	1.80E-04	6.00E-05	3.00E-05	3.86E-05	0	3.09E-04	24 %
Operational	4.10E-05	1.35E-05	7.00E-06	9.02E-06	0	7.05E-05	5 %
External Corrosion	1.30E-04	3.65E-05	1.80E-05	0	0	1.85E-04	14 %
Internal Corrosion	9.00E-05	2.60E-05	1.30E-05	0	0	1.29E-04	10 %
Natural Hazards	2.85E-04	9.50E-05	4.75E-05	3.06E-05	0	4.58E-04	35 %
External Impact	5.50E-05	3.55E-05	3.55E-05	2.83E-05	5.80E-06	1.60E-04	12 %
Total	7.81E-04	2.67E-04	1.51E-04	1.07E-04	5.80E-06	1.31E-03	100 %

***Damage size is given as hole diameter, damage assumed to be circular**

Two scenarios have been defined with respect to release rate and release duration. This is illustrated in Table 14.18.

Table 14.18 Release rates and duration – ship loading pipelines

Scenario	Release rate, prior to shut down of loading operation	Average release rate per pipeline – loading operation is shut down	No. of pipelines damaged	Detection & shut down time	Total release to sea (tonnes)
Minor	10 kg/s	10 kg/s	1	4 hours	144
Large	2250 kg/s	2 x 2000 in 1 hour	2	10 minutes	6700

With reference to Table 14.17**,** the frequency of the scenarios specified in Table 14.18 are assessed by assuming that:

- Minor release = release damage categories “small” + “25mm” + “50mm”;
- Large release = release damage categories “100mm” + “rupture”.

Table 14.19 presents the frequency assessed for these scenarios.

Table 14.19 Accidental release scenarios related to ship loading pipelines

FAILURE MODE	MINOR	LARGE	TOTAL
Defects	2.70E-04	3.86E-05	3.09E-04
Operational	6.15E-05	9.02E-06	7.05E-05
External Corrosion	1.85E-04	0	1.85E-04
Internal Corrosion	1.29E-04	0	1.29E-04
Natural Hazards	4.28E-04	3.06E-05	4.58E-04
External Impact	1.26E-04	3.41E-05	1.60E-04
Total	1.20E-03	1.12E-04	1.31E-03
Distribution in% of total	91 %	9 %	100 %

14.3.1.4 Release to the sea from crude oil tankers

Overloading of cargo tanks

Overloading of cargo tanks is most likely to be caused by a technical failure of the alarm-system or human failure related to operation. The frequency of large spill due to overloading is found from Table 14.13 to 4.2E-04 per year.

The scenario assumed for a large spill due to overloading is that a cargo tank is overloaded, and oil is released on to the main deck through the PV- valve with a rate of 9540m^3/h (=loading capacity rate). It is assumed that the overloading will be detected and shut down 30 minutes after it started. Approximate 2,000 tonnes of the oil spill will be retained on deck, while the total amount of oil spilt to the sea will be about 2,000 tonnes. The accidental release scenario related to overloading of export tankers will have a frequency of 4.2E-04 per year, and the amount of oil released will be 2,000 tonnes within 15 minutes.

14.3.1.5 Structural failure

Frequency of structural failure for crude oil tankers has been assessed based on analysis of relevant data from the LMIS database (Loyds' Maritime Information System). Analysis of the data gives a total frequency of structural failure with potential to cause oil spill from tankers of 3,0E-04 per year.
Figure 14.3 presents the event tree model used for assessing the release risk related to structural failure on tankers, which can be summarised as follows.

- Small release: 45 tonnes within 12 hours with a frequency of 5.4 E-05 per year;
- Large release: 10 000 tons within 12 hours with a frequency of 6.8 E-05 per year.

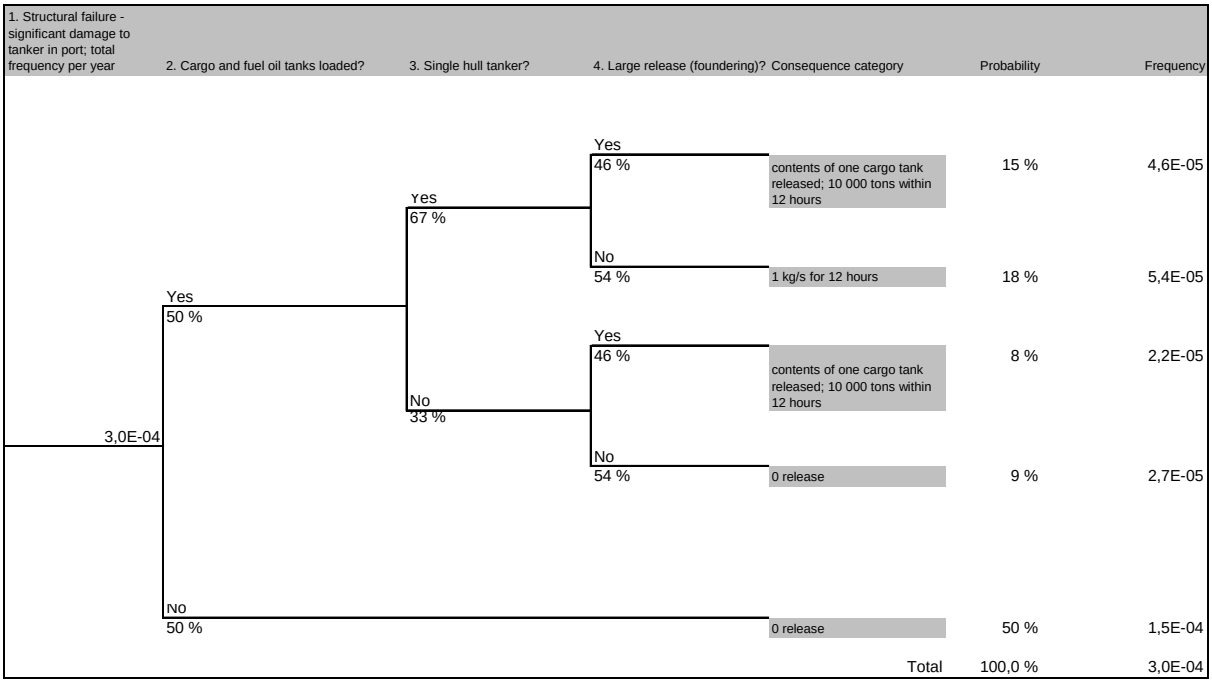

Figure 14.3 Event tree risk model – release from export tanker due to structural failure

Fire/explosion

A fire and/or explosion in the cargo area may damage the cargo tanks so that crude oil is released to the sea. Analysis of the LMIS data gives a frequency of 3.4E-04 per ship year for fire/explosions in cargo area for tankers. This is the frequency of events causing serious damage to, or total loss of, the ship. It is assumed that these events also have the potential to cause release of crude oil from the cargo tanks. The total yearly tanker loading activity at the terminal is 0.99 ship-years. Thus, the frequency of fire/explosion in cargo area with potential to cause release of crude oil to the sea is 3.3E-04 per year.

Given a fire/explosion in the cargo area two cargo tanks are assumed severely damaged. The cause of the damage will most likely be an explosion in one cargo tank. The cargo tanks involved are assumed to be half-filled, thus 10,000 tonnes is expected to be released to sea within 1 hour. It is assumed that 80% of the released oil will burn, thus 2,000 tonnes of the oil spill can drift away.

Impact from other ship

The following collision scenarios are considered possible with respect to causing release of cargo or fuel oil:

- tug impacts with tanker;
- arriving/departing tanker impacts with another tanker due to operational error (violation of port regulations);
- passing ship accidentally (due to technical or operational error) impacts with tanker in terminal area.

Figure 14.4 presents the event tree model used for assessing the release risk related to ship impact to export tankers frequencies are based on LMIS data.

The risk can be summarised as follows:

- Small release: 45 tonnes within 12 hours with a frequency of 2.8E-04 per year;
- Medium release: 2000 tonnes within 12 hours with a frequency of 2.4 E-05 per year;
- Large release: 10 000 tonnes within 12 hours with a frequency of 1.8 E-04 per year.

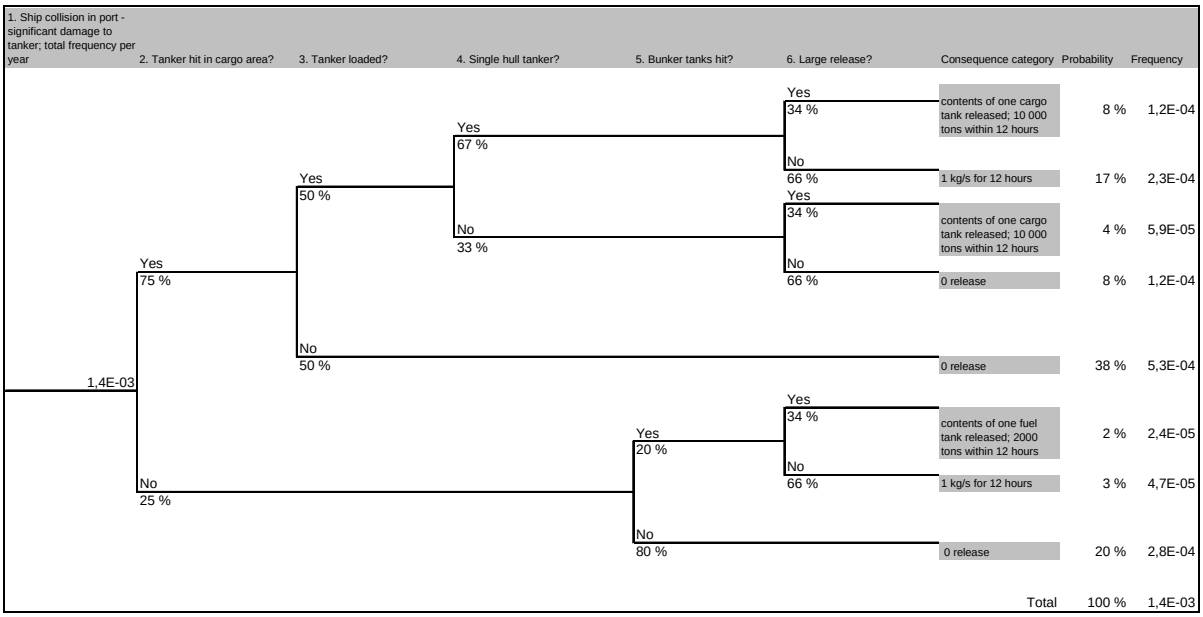

Figure 14.4 Event tree risk model – release from export tanker due to ship collision

Impact with berth on arrival/departure

A tanker impacting with the jetty on departure may cause release of oil if cargo tanks are damaged. Release from fuel tanks may occur as well in case of jetty impact, both on arrival and departure.
Figure 14.5 presents the event tree model used for assessing the release risk related to ship impact to export tankers, frequencies are based on LMIS data. The risk can be summarised as follows:

- Small release: 45 tonnes within 12 hours with a frequency of 1.2 E-04 per year;
- Small release: 200 tonnes bunker fuel within 12 hours with a frequency of 2.6 E-05 per year;
- Medium release: 2000 tonnes within 12 hours with a frequency of 1.3 E-04 per year.

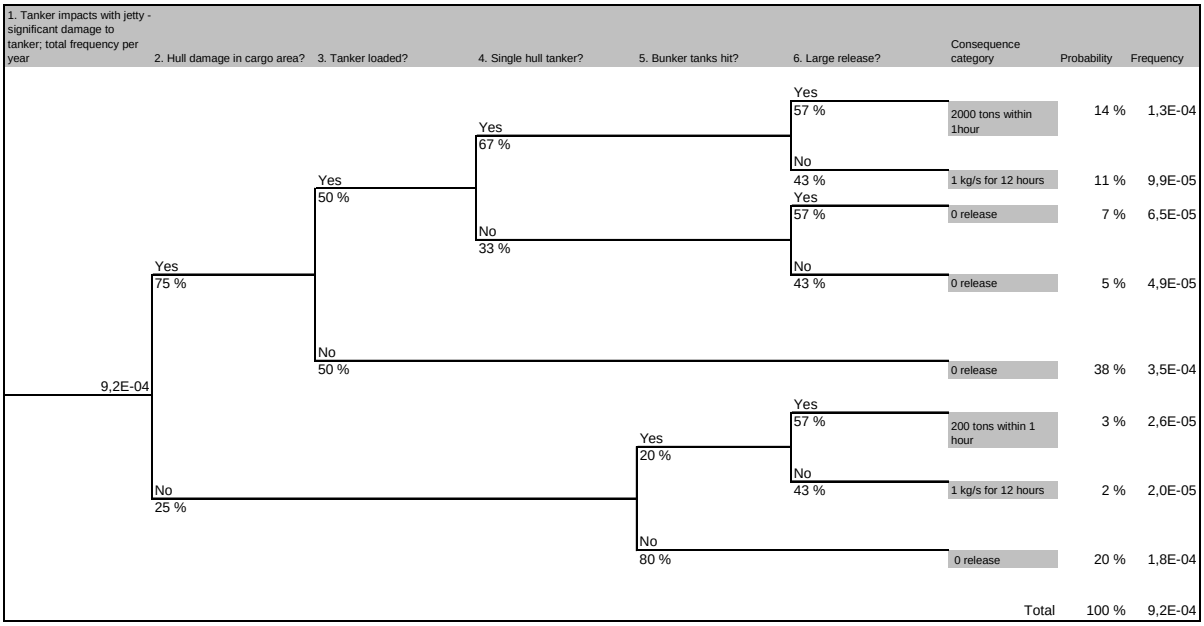

Figure 14.5 Event tree risk model – release from export tanker due to impact with jetty

14.3.1.6 Collapse of onshore oil storage tanks and release to the sea

The tank farm consists of seven atmospheric storage tanks, each with a storage capacity of 126,000 tonnes. The tanks are to be located on a height 120 – 130m above sea level. The tank farm will be designed to meet the requirement for safe shutdown for an earthquake with a return period of about 2,500 years.

The shortest distance between the tank farm and the sea is about 1,5km. Based on information from maps and drawings it seems possible that a large release of crude oil from the tank farm may reach the sea. Such large releases are only likely to be caused by a major earthquake significantly exceeding the design limits of the tank farm.

Based on the geohazard study and the Seismic Design Criteria report, earthquake frequencies as function of intensity and damage severity are presented in Table 14.20, a total frequency of 9E-06 per year has been assessed for earthquakes with potential to collapse of one or more storage tanks and bunds. It is assumed that only one tank and bund will collapse and that 50% of the spilled oil will reach sea. The spill to sea will last for about 24 hours. As a summary, the spill scenario is a total discharge of 63 000 tonnes oil to sea within 24 hours with a frequency of 9E-06 per year.

Table 14.20 Earthquake intensity vs frequency for the BTC Marine Terminal area

MM Intensity*	Damage	Frequency per year	Moderate damage	Severe damage
VIII	Moderate damage	2.0E-04	2.0E-05	0.0E+00
IX	Heavy damage	1.0E-04	5.0E-05	0.0E+00
X	Extreme damage	2.0E-05	6.0E-06	4.0E-06
XI	Profound damage	1.0E-05	0.0E+00	5.0E-06

***Modified Mercalli Intensity**

14.3.1.7 Summary of accidental release scenarios

The TRA risk results; accidental release scenarios, are summarised in Table 14.21.

Table 14.21 Summary of risk results - accidental release scenarios

#	Description	Main causes	Release rate	Release duration	Frequency (per year)
1	**Release from loading arms**				
1.1	Minor release from one loading arm	Mechanical Defects. Corrosion. Wear and Tear. Operational Error.	1 kg/s	4 hours	1.63E-02
1.2	Large release from loading arms	Drift-Off	17 tonnes - 200 tonnes within 15 - 120s	15 – 120 seconds	7.19E-03
2	**Release from loading pipelines to the sea**				
2.1	Small/moderate size release from loading pipeline	Mechanical Defects. Corrosion. etc.	10 kg/s	4 hours	1.20E-03
2.2	Large release from loading pipelines	Ship Impact. Earthquake	6700 tonnes in 1 hour	1 hour	1.1E-04
3	**Release from crude oil tankers**				
3.1	Overloading of cargo tank	Operational/Technical Error	2000 tonnes in 15 minutes	< 1 hour	4.2E-04
3.2	Release from vessel piping system during loading	Mechanical Defects. Corrosion. Wear and Tear. Operational Error. etc.	Spill will be contained on deck of the tanker. Release to sea is thus not considered likely.	-	0
3.3	Minor release of cargo or fuel oil due to crack in tanker hull	Structural Failure. Impact from other Ships, Impact with Jetty	1 kg/s	12 hours	4.5E-04
3.4	Large release from vessel cargo tanks	Structural Failure. Impact from other ships.	10000 tonnes within 12 hours	12 hours	2.5E-04
3.5	Large release from vessel fuel oil tanks	Impact from other ships.	2000 tonnes within 12 hours	12 hours	2.4E-05
3.6	Large release from vessel cargo tanks	Fire/Explosion. Impact with Jetty	2000 tonnes within 1 hour	1 hour	4.7E-04
3.7	Release from vessel fuel oil tanks due to impact with jetty	Impact with Jetty	200 tonnes within 1 hour	1 hour	2.6E-05
4	**Release from tanker fuelling operations**				
4.1	Release from fuelling operations	Operational/technical error	Not relevant as such operations are not to take place in the terminal area	-	0
5	**Release from onshore tankfarm**				
5.1	Release from rupture of onshore storage tank and bund resulting in oil running in to the sea	Major earthquake	50% of the contents of one tank (63,000 tonnes) are estimated to enter the sea in 24 hours.	24 hours	9.0E-06

As the consequences, in terms of release rate and duration, of several of the accidental release scenarios presented above are quite similar, the total number of scenarios have been reduced to 4, as presented in Table 14.22. The environmental risk associated with these scenarios has been analysed further in the ERA. The total release frequency is not affected by the reduction of the number of scenarios.

Table 14.22 Accidental release scenarios analysed further in the ERA

Scenario	Category	Total Spill (tonnes)	Rate (tonnes/hour)	Duration	Frequency	Hazard #
1	Small spill	4 - 200	4 - 200	1 - 4 hours	2.40E-02	1.1 - 1.2 - 2.1 - 3.3 - 3.7
2	Medium spill	200 - 2000	170 - 2000	1 - 12 hours	4.70E-04	3.1 - 3.5 - 3.6
3	Large spill	2000 - 10 000	850 - 7000	1 - 12 hours	2.46E-04	2.2 - 3.4
4	Very large spill	> 10 000 (63 000)	2600	24 hours	9.00E-06	5.1

14.3.2 Oil drift simulations

Simulations of the transport and fate of oil on the sea surface were performed with the model OILTRAJ without any mitigation such as those proposed in the Oil Spill Response Programme. OILTRAJ combines the changes in the spilled oil properties with current and wind inputs to simulate statistical persistence and drift trajectory of the spilled oil. The model calculates, amongst other aspects, oil pollution probability, mass factors (evaporated, dispersed and remaining part of oil) and arrival time in a 1×1km grid. The transport of the discharged oil is computed by means of several trajectories for a given wind history for the area considered. The wind may vary both in space and time, while the main ocean surface currents are assumed to vary in space, but not in time. However, wind generated ocean currents are computed based on statistical wind data, this current varies both in space and time according to the wind variations. The simulation of the fate of the discharged oil includes algorithms for the evaporation, emulsification, dispersion, viscosity and density.

The oil drift simulations are performed with the characteristics of Azeri crude oil. OILTRAJ was applied to model the drift of oil for the four oil spill scenarios shown in Table 14.22. The oil drift is modelled for two seasons; winter half-year (October – March) and summer half-year (April – September).

The result for the winter season (see Figure 14.6 and Figure 14.7) show that the most likely fate of the oil is for rapid beaching close to the release position Most of the oil will remain principally within the bay. The dominant north-east wind component, together with the south westward sea current at the west coast, will make part of the oil leave the Iskenderun Bay. The likelihood that oil will leave the bay is < 3%. For the small spill scenario, the pollution probability is within 5-20% in about 20% of the area in the Bay. For the medium, large and very large spill the 5-20% limit cover about 35%, 60% and 70% respectively. During relatively strong offshore winds the oil moves and beaches on the east and southern coasts of Iskenderun Bay.

In the summer season (see Figure 14.8 and

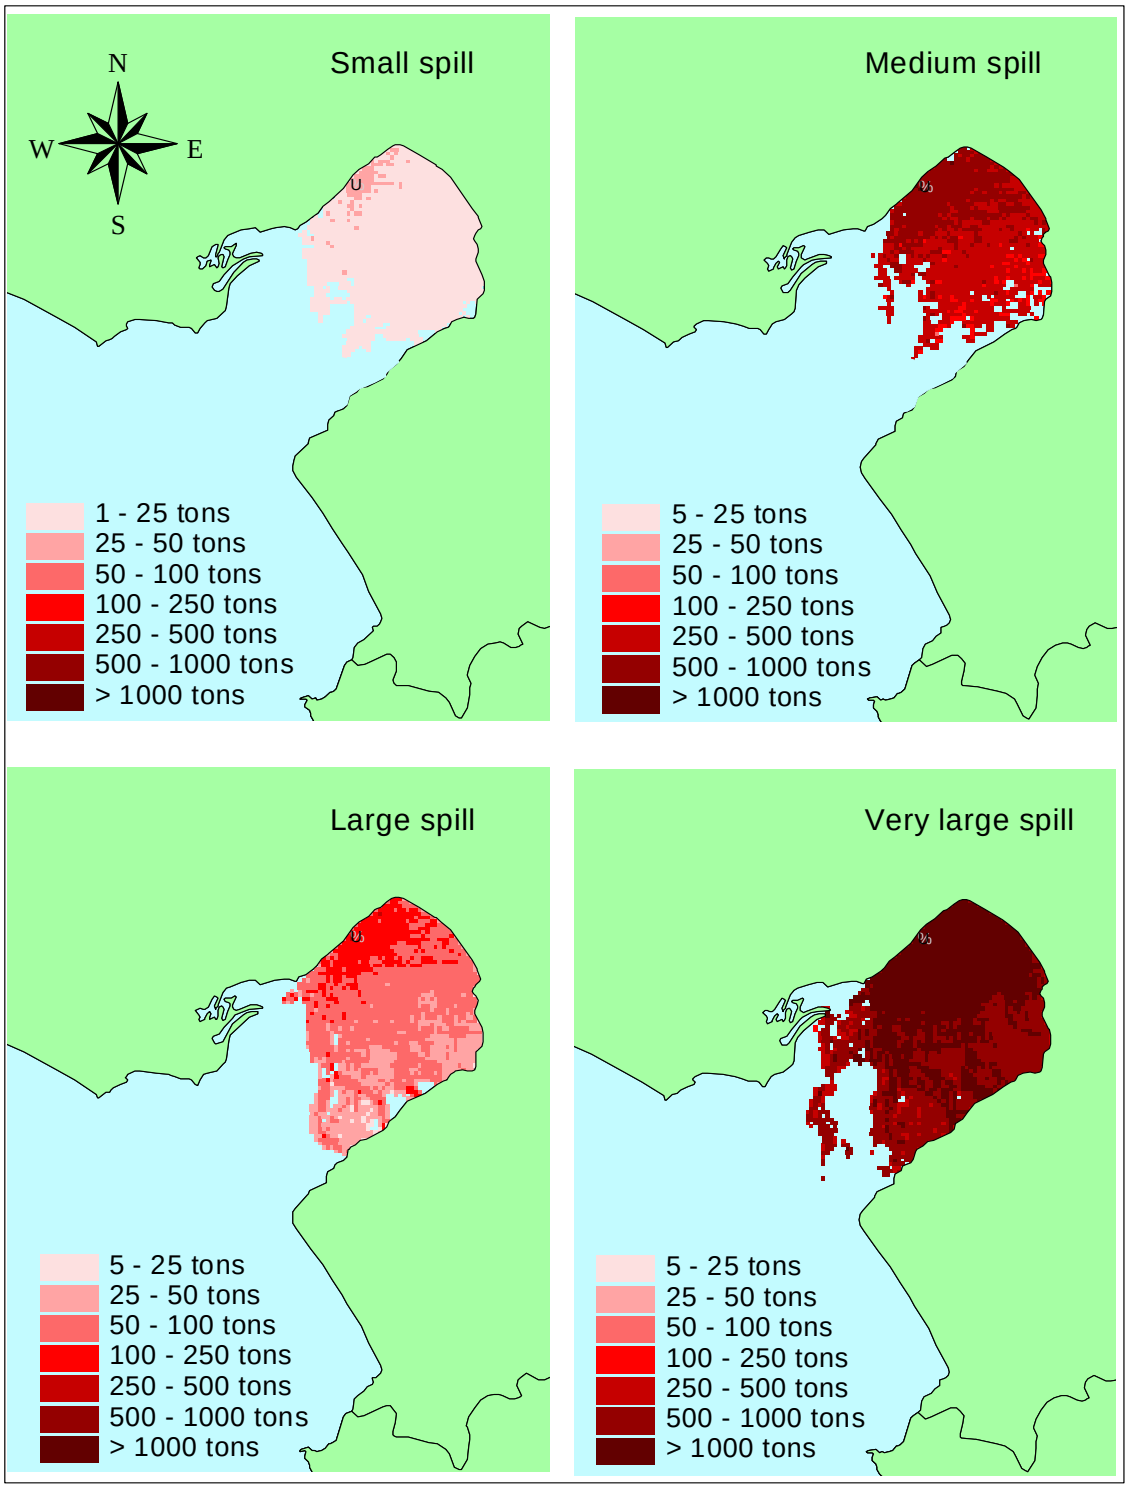

Figure 14.9) the most likely fate of the oil will be rapid beaching close to the release position. The oil will remain principally within the Bay within 1% pollution probability. The dominating south/south west wind component together with the clockwise current circulation will prevent the oil slick from leaving the Iskenderun Bay. The likelihood that oil will leave the Bay is < 1%.

For the small spill scenario, the pollution probability is within 5-20% in about 25% of the area in the Bay.

For the medium, large and very large spill, the 5-20% limit cover will be about 35%, 50% and 60% respectively.

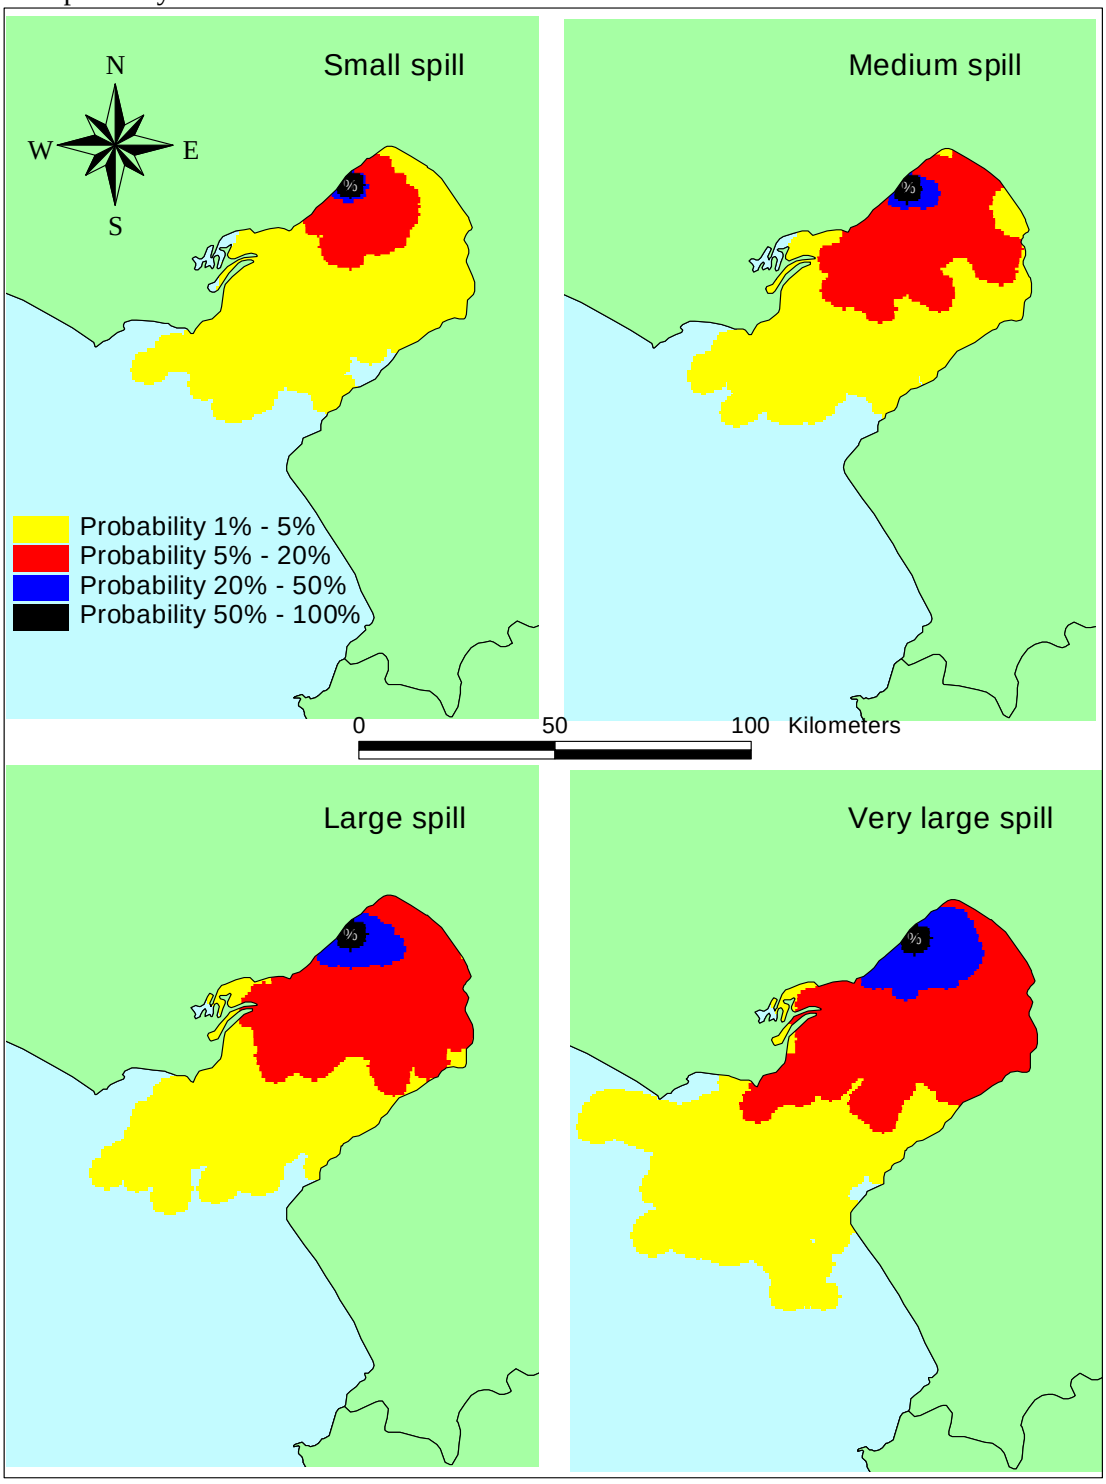

Figure 14.6 Pollution probability from the oil drift simulations for the winter season, (October – March) scenario 1 – 4

Figure 14.6 shows the influence area where the pollution probability is greater than 1% and the average oil quantity is greater than 5 tonnes (1 ton for the small spill scenario). The release position is marked with a grey square.

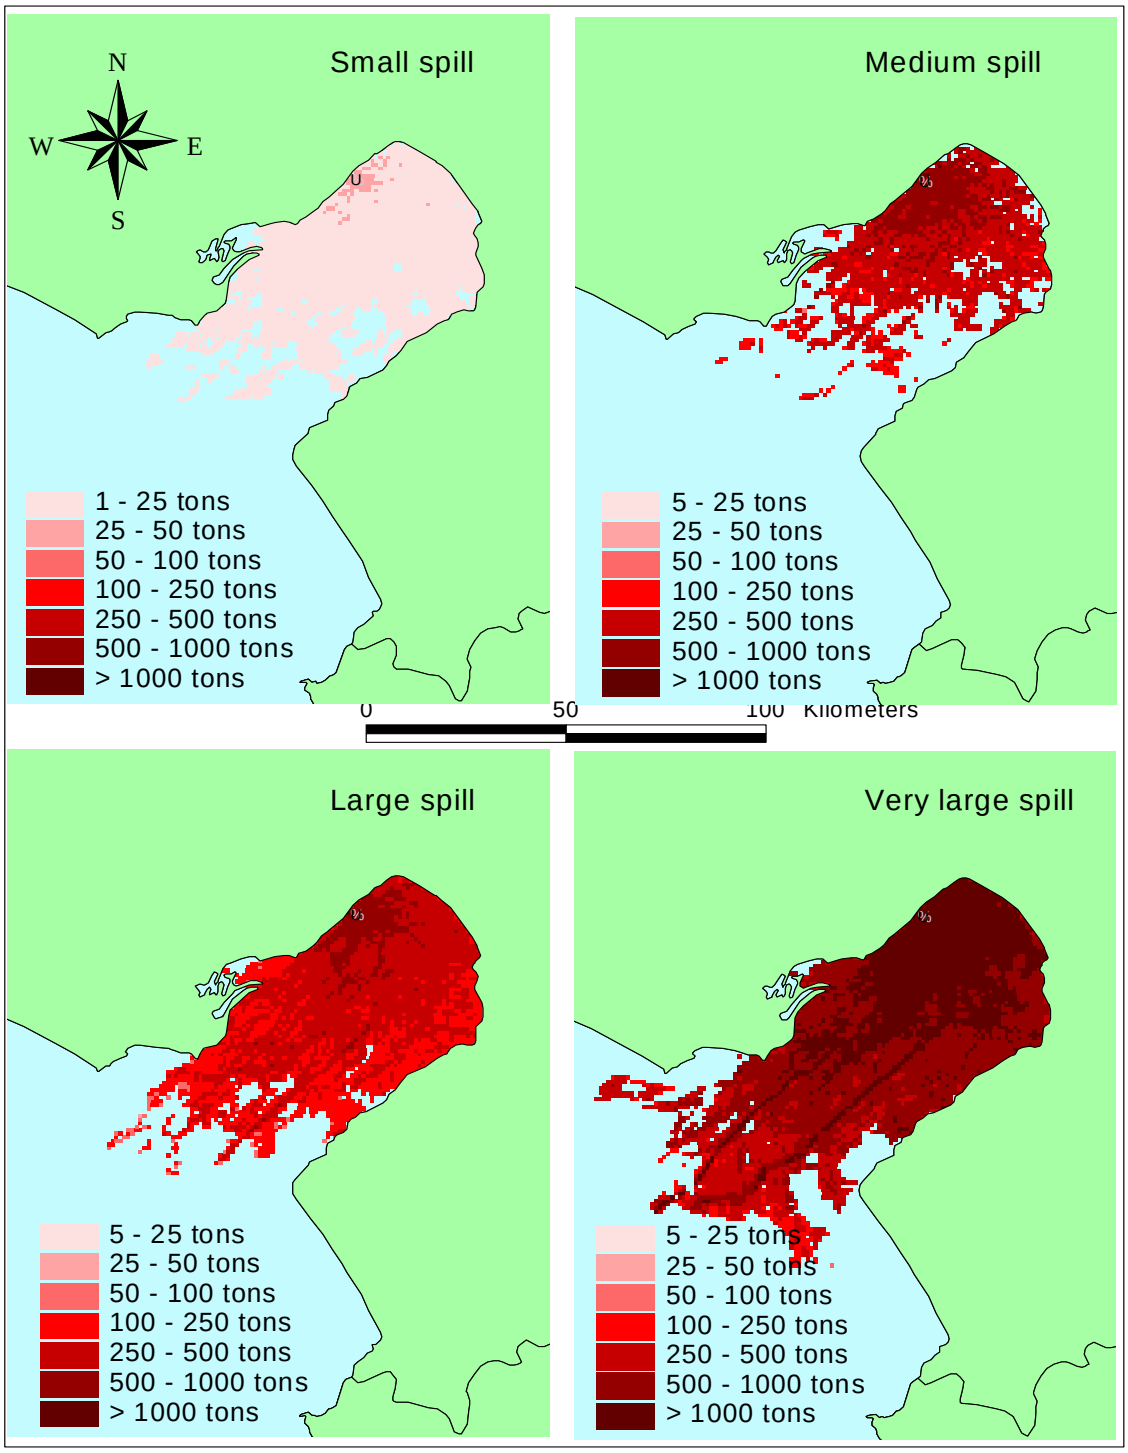

Figure 14.7 Average oil (not emulsified) quantity in tonnes for the winter season (October – March) scenario 1 – 4

Figure 14.7 shows the influence area where the probability is greater than 1% and the average oil quantity is greater than 5 tonnes (1 ton for the small spill scenario). The release position is marked with a grey square.

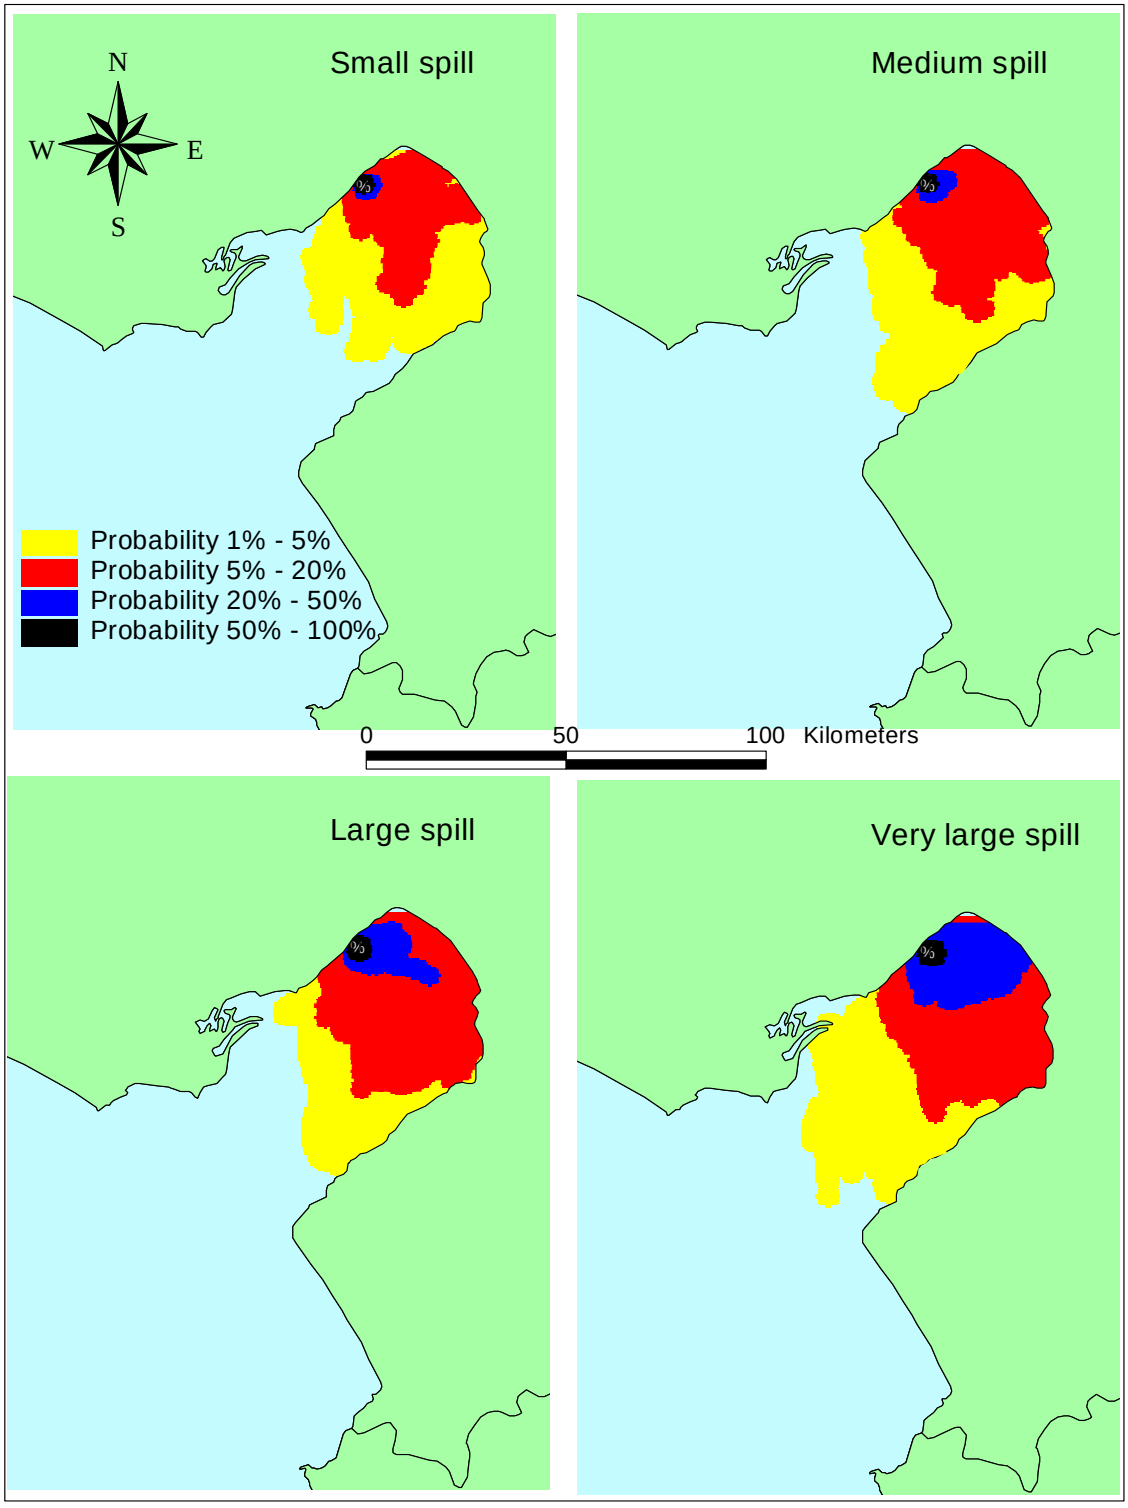

Figure 14.8 Pollution probability from the oil drift simulations for the summer season, (April – September) scenario 1 – 4

Figure 14.8 shows the influence area where the pollution probability is greater than 1% and the average oil quantity is greater than 5 tonnes (1 ton for the small spill scenario). The release position is marked with a grey square.

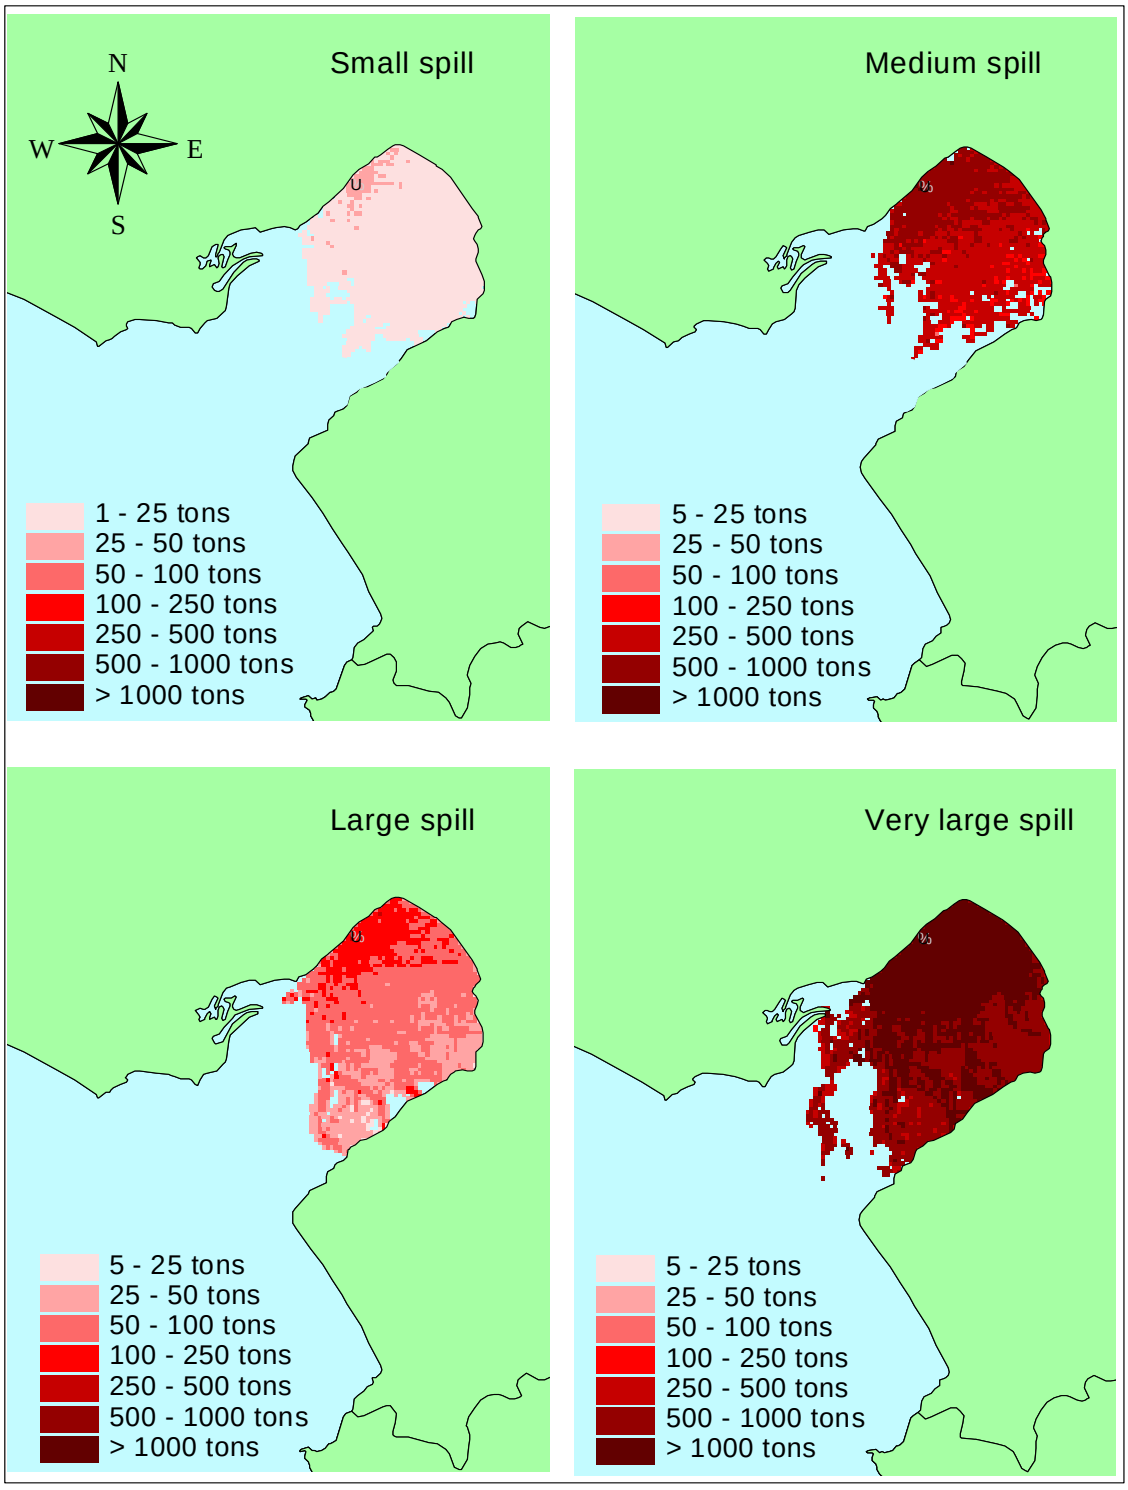

Figure 14.9 Average oil (not emulsified) quantity in tonnes for the summer season (April – September) scenario 1 – 4

Figure 14.9 shows the influence area where the probability is greater than 1% and the average oil quantity is greater than 5 tonnes (1 ton for the small spill scenario). The release position is marked with a grey square.

14.3.3 Valued ecosystem components

The most important natural resources in and around the Gulf of Iskenderun are described in Section 6 of the ERA report (DNV report no: 2002-0396), with special emphasis on resources that are potentially vulnerable to oil pollution (including fisheries and aquaculture). Based on this review, a selection of Valued Ecosystem Components (VEC) has been chosen for this ERA study. The priority list of VECs are those resources that are considered to be the most important and valuable, in combination with a high vulnerability to oil pollution, which will be assessed with respect to the assessment of environmental risk. The list of selected VECs for this ERA study is shown in Table 14.23 below. The assessment of the consequences of the identified oil spill scenarios, for each of the listed VECs, is presented in section 14.3.4.

Table 14.23 Selected VECs for the ERA study of the BTC MarineTerminal

VEC#	Resource category	Name	Description
1	Fish and Fisheries	Various fish species	Gulf of Iskenderun is one of the most productive fishing areas in the Turkish part of the Mediterranean. It is both a locally and regionally important fishing area. Local fishermen use small boats and catch fish in shallow waters along the coast, while the regional fishing takes place with trawlers all over the Gulf. Iskenderun Gulf has several important spawning grounds, among the most important is the Yumurtalik Lagoon.
2	Saltmarshes	Yumurtalik Lagoons	The Yumurtalik Lagoons area is a wetland complex for breeding birds and large numbers of wintering waterbirds. The site is recognised nationally as a Nature Reserve Area and qualifies as an IBA under both global and European criteria with a high national protection status. The wetland consists of coastal lagoons, mud and sand flats, saltmarshes, sand dunes, beaches and water fringe vegetation. Saltmarshes are extremely vulnerable to oil spills as they serve as nursery and breeding ground for fish. They can trap and retain large quantities of oil, they are difficult to clean, and the anaerobic conditions present slow down the natural degradation of oil. Recovery time for saltmarshes varies from about two years to decades.
3	Waterfowl	White-headed Duck (winter)	The White-headed duck populations are distributed into a small resident population in Spain and the Western Mediterranean and a larger migratory population in the Eastern Mediterranean across to Central Asia. The White–headed Duck is a coastal surface feeding bird that breeds on small stagnant wetlands, usually brackish with no outflow and fringed with dense emergent vegetation. Breeding in Europe is concentrated in southern Spain, but it also occurs in Russia and Romania. North-eastern Greece, the western Black Sea coast and Turkey are important wintering areas for birds breeding in European Russia and further east. Large numbers of the White-headed Duck winter at Agyatan lake, Akyatan lake and the Yumartalik lagoons. The wintering populations qualify for the IBA criteria A1, which means that this is a species of global conservation interest. Due to the breeding habitat and the fact that the White-headed duck is a globally threatened species, this bird is very vulnerable to oil pollution.

VEC#	Resource category	Name	Description
		Kentish Plover (breeding/ summer)	The Kentish Plover is a small wader that most often breeds in sparsely vegetated sites along seacoasts, lagoons, estuaries and beaches. In Europe, the Kentish Plover populations are distributed predominantly at the coasts of the western Baltic, North Sea, Atlantic Ocean, Mediterranean Sea and the Black Sea. The breeding populations of Kentish Plover at Agyatan lake, Akyatan lake and the Yumartalik lagoons qualifies for the IBA criteria B2, which means that this species has a threatened conservation status in Europe, and for which the site-protection approach is thought to be appropriate. Large numbers of the Kentish Plover also pass by or winter at these IBAs. Due to their breeding habitat, these birds are very vulnerable to oil pollution.
4	Sea turtles	Green Turtle	The Green Turtle are in danger of extinction. It is listed as critically endangered (CR) in the 2000 IUCN Red List of Threatened Species. Groombridge (1990) estimated that only 300 to 400 Green Turtle females nest annually in the entire Mediterranean. Even with this threatened status, they are regarded as the second most abundant population of turtles in the Mediterranean Sea. Green Turtle are more numerous than any other sea turtle species within the actual area. There are only three important nesting beaches along the Turkish coast, and all are located within the area between Mersin Bay and Gulf of Iskenderun. This area holds more than 70% of the Green Turtles nests in the entire Mediterranean Basin (Yerli and Demirayak, 1996).
5	Sea mammals	Monk Seal	The most sensitive sea mammal in the area in and around the Gulf of Iskenderun is the Monk seal. Monk seal has had a drastic decline in population size all over the world. The Mediterranean Monk seal is considered as a distinct species due to the large geographical separation between this population and populations in the Pacific ocean. The Mediterranean monk seal is listed as critically endangered by the International Union for the Conservation of Nature and Natural Resources (IUCN). This species is also listed on Appendix I of the Convention on International Trade in Endangered Species (CITES). They are extremely sensitive to human disturbance, today the Mediterranean monk seal numbers between 300- 500 animals. Monk seals reproduce slowly, sometimes only every other year, starting at the age of four. Adult females, larger than the males, come ashore to give birth to one pup, then remain on the beach nursing and protecting the pup for up to six weeks. Living off stored fat, the female does not leave the pup even to feed herself during this period. The pup may stay with its mother for as long as three years after weaning.

14.3.4 Impact of oil pollution on Valued Ecosystem Components, assessment of consequence values

Risk assessment is an evaluation and quantification process where both the probability and consequences of an accidental event are estimated, and the combination of these constitutes an expression of the risk.

Guideline consequence assessment parameters (Table 14.24) have been developed which allow qualitative assessments of environmental consequences to be classified and ranked quantitatively. These consequence parameters are used to assess the potential impact to selected Valued Ecosystem Components (VEC).

In the ERA, such resources will serve as risk indicators and will provide a sufficient basis for assessing the risk level and as a basis for identifying and designing risk reduction measures, including oil spill preparedness.

Table 14.24. Guideline consequence assessment parameters for the BTC Marine Terminal ERA

Consequence level	A	B	C	D	E
	Ecological effects:				
	Recovery time	**Percent of area affected**	**Conservation value of VEC**	**Socio-economic impact**	**Economic value of VEC**
1 Negligible	Not detectable	Not detectable	-	Not detectable	-
2 Minor	Detectable, but short duration; recovery time less than one year	1-5%	No classification	Minor; limited extent (insignificant)	Minor
3 Moderate	Recovery time less than 5 years	5-15%	Regional/local	Moderate; impact on local level	Moderate
4 Major	Recovery time less than 10 years	15-30%	National	Major; impact on regional level	High
5 Severe	Recovery time more than 10 years	>30%	International	Severe; impact on national level	Very high
Weighting factors if parameter B is applicable	**25%**	**25%**	**20%**	**20%**	**10%**
Weighting factors if parameter B is not applicable	**50%**	**-**	**20%**	**20%**	**10%**

The five consequence parameters are assessed for each spill scenario, in both winter and summer half-years. Based on scientific evaluations each parameter is classified with a value from 1 to 5. An average value is then calculated on the basis of the weighting factors (shown in the two lowest rows of Table 14.24) to provide an overall consequence value (CV).

The impact assessment of VECs has been carried out in a semi-quantitative manner. All assumptions drawn to assess the consequence values for each consequence parameter are outlined in the section for impact assessment in DNV Report No. 2002-0396. Each consequence parameter is weighted and a total consequence parameter for each spill scenario is calculated. The following four assessments show the consequence values for the actual VECs.

14.3.4.1 VEC 1: Fish and Fisheries

Gulf of Iskenderun is one of the Levant seas', in fact one of the Mediterranean seas', most productive areas for fisheries. Fisheries are an important source of food and income for households in Gulf of Iskenderun. Furthermore, the Gulf of Iskenderun is a regionally important area for trawl fishing. Potential effects on fisheries can be divided into direct effect on fishery species, an indirect effect as ecosystem disturbance and direct effect as tainting and loss of commercial interest for the fish.

Ecological recovery time is first of all relevant in relation to effects on the survival of eggs and larvae spawned in shallow waters. Estimated recovery periods after impacts of a theoretical oil spill from the BTC Marine Terminal are outlined in Table 14.25. Due to highest spawning activity in the summer, the consequences of a very large spill are higher than for the winter.

Table 14.25 Estimated recovery time for ecological effects of oil spill

Scenario	WINTER		SUMMER	
	Recovery time	Consequence category	Recovery time	Consequence category
1 small spill	Insignificant	1	Insignificant	1
2 medium spill	Insignificant	1	Insignificant	1
3 large spill	< 1 year	2	< 1 year	2
4 very large spill	< 1 year	2	< 5 years	3

The criteria for the assessment of socioeconomic impact of an oil spill is categorised based on the percent of the Gulf that has more than 5% probability of being polluted with more than 50 ton oil per km^2:

- less than 20% of the Gulf no significant effect
- 20%-80% of the Gulf local effect
- more than 80% of the Gulf regional effect

Table 14.26 shows the assessment of the impact of an oil spill in Gulf of Iskenderun. The effects are divided into the four spill scenarios that are based on the TRA results. The consequence values are shown in Table 14.27.

Table 14.26 Effects on fisheries

Scenario		Summer		Winter	
		% of Iskenderun Gulf that has more than 5% probability of being affected with more than 50 ton oil per km^2	Consequence	% of Iskenderun Gulf that has more than 5% probability of being affected with more than 50 ton oil per km^2	Consequence
1	Small	2 %	no significant effect	1 %	no significant effect
2	Medium	25 %	local effect	26 %	local effect
3	Large	37 %	local effect	62 %	local effect
4	very large	81 %	regional	90 %	regional

Table 14.27 Consequence assessment for VEC 1: Fish and fisheries

		2			
		3			
		4			
Total consequence value for VEC 1: fish and fisheries		**1**	**1,5**	**1,5**	
		2	**1,9**	**1,9**	
		3	**2,4**	**2,4**	
		4	**2,6**	**3,1**	

14.3.4.2 VEC 2: Saltmarshes, Yumurtalik Lagoon

Saltmarshes are found globally and are often protected areas due to their provision of nursery areas and form productive food web support for fish. They serve as important habitats for wildlife species such as wading birds, and are used as grazing land in some regions. Of all estuarine and coastal environments, saltmarshes are among the most ecologically sensitive areas with respect to oil spills because they can trap and retain significant quantities of oil and because they are very difficult to clean. These habitats are also categorised as 'most vulnerable' according to the international shoreline vulnerability indices. In this risk assessment, a categorisation of recovery time of an oil saltmarsh is based on the categorisation applied in the method for quantitative environmental risk assessment developed by OLF and DNV (OLF 2001). The matrix in Table 14.28 shows the relation between oil pollution and recovery time for a sensitive shoreline.

Table 14.28 Matrix of relation between oil pollution and recovery time for sensitive shorelines.

	Consequence category/Recovery time				
	1	2	3	4	5
Ton oil in 1 km^2	insignificant	<1 year	1-5 years	5-10 years	>10 years
< 5	50 %	50 %			
5-50	10 %	60 %	20 %	10 %	
50-500			20 %	50 %	30 %
>500				40 %	60 %

The four scenarios for an oil spill from the BTC Marine Terminal has more than 1% probability of hitting the salt marshes of Yumurtalik Lagoon with oil amounts per km^2 as shown in Table 14.29. The consequence number is calculated by weighting the consequence categories with the probability for the consequence category related to the actual oil amount (see Table 14.28). As an example 50-500 ton/km^2 gives the consequence:

$$3 \times 0.2 + 4 \times 0.5 + 5 \times 0.3 = 4.1$$

Table 14.29 shows the amount of oil in km^2 with more than 1% probability for pollution of the saltmarshes. It also shows the related consequence that is weighted, based on the impact matrix in Table 14.28 above.

Table 14.29 Seasonal Impacts to Oil Spills and Consequence Analysis

Scenario		Winter		Summer	
		Ton oil/km^2	Consequence	Ton oil/km^2	Consequence
1	small	0	1	0	1
2	medium	5-50	2,3	0	1
3	large	50-500	4,1	0	1
4	very large	>500	4,6	>500	4,6

In addition to oil amount beached at saltmarshes, the size of the polluted area is an important parameter to assess the impact on saltmarshes. The total length of shoreline with saltmarsh in Yumurtalik Lagoon is roughly 60km.

Table 14.31 shows the length and percent of the saltmarsh shoreline that has more than 1% probability for oil pollution. The consequence values are derived from the following categorisation in Table 14.30.

Table 14.30 Consequence and Probability

Consequence	Percent of area with more than 1% probability for oil pollution
1	Not detectable
2	1-10%
3	10-30%
4	30-50%
5	>50%

Table 14.31 Percent of sensitive saltmarsh area with more than 1% probability for oil pollution

	WINTER			SUMMER		
Scenario	km affected	% of shoreline	Consequence	km affected	% of shoreline	consequence
1	15	25 %	4	0	0 %	1
2	25	42 %	5	0	0 %	1
3	60	100 %	5	0	0 %	1
4	60	100 %	5	9	15 %	3

The consequence assessment is summarised in Table 14.32. The consequences are highest in the winter period, due to more frequent wind directions that can drift the oil into the lagoon.

Table 14.32 Consequence assessment for VEC 2; Saltmarsh (Yumurtalik Lagoons)

VEC 2: Saltmarsh (Yumurtalik Lagoon)	Consequence Assessment	Scenario	Winter	Summer	Weighting Factor
Ecological recovery time	Ecological consequences are outlined in the Section and summarised in Table 14.29	1	1	1	**25 %**

		2	**2,9**	**1,8**	
		3	**3,6**	**1,8**	
		4	**3,7**	**3,2**	

14.3.4.3 VEC 3: Waterfowl

There is a significant bird population that over-winters in the wetlands and along the coast within the influence area of a theoretical oil spill from the proposed BTC Marine Terminal. The White-headed duck is a globally threatened species, which has a significant part of its population over-wintering within the area potentially influenced by oil spills. In the summer time breeding species are of concern, one of the most vulnerable is the Kentish Plover that nest at mudflates close to the shoreline. This is a species with a threatened population status in Europe and with high density within the area of concern.

For the risk assessment, it assumed that the majority of the birds are within the stippled line in the map (Figure 14.10). It is also assumed that 50% of the birds are along the shoreline, while the other 50% are in the lakes. The total size of the marine part of the bird roosting area is 350km^2.

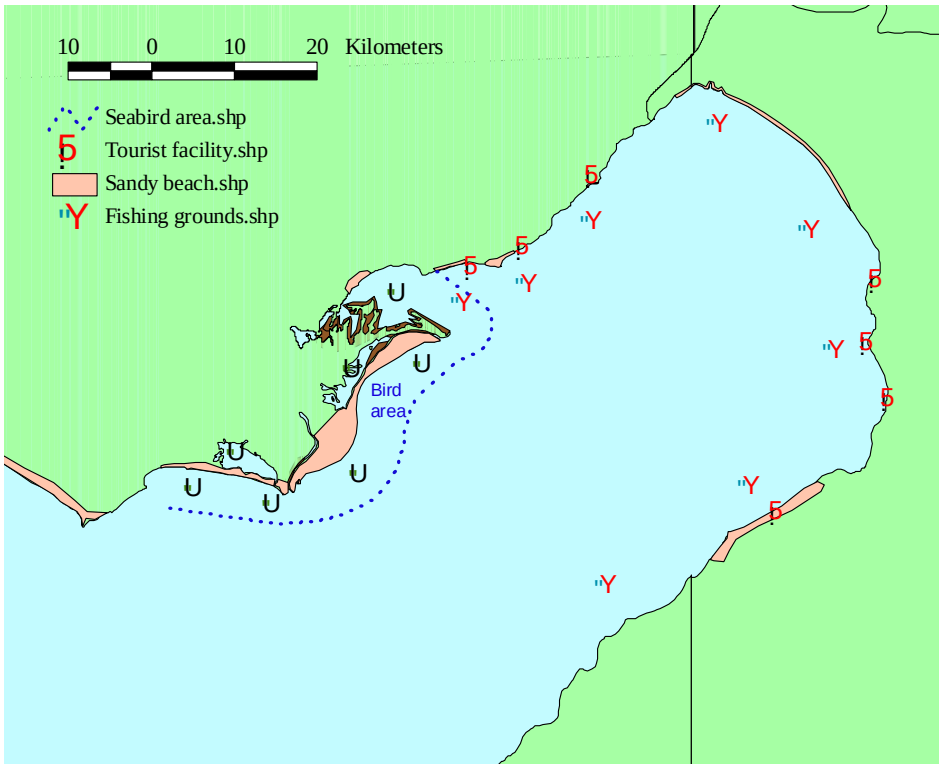

Figure 14.10 Areas were the bird density is significantly high.

The estimated recovery times of theoretical oil pollution incident on the important waterfowl areas are shown in Table 14.33. The recovery time is shown for a range of seasonal conditions. The recovery time is estimated by assessing the total percentage of birds in the area that would die as a result of an oil pollution incident. The key aspects of the assessment are the size of the oil spill and the area affected by the oil spill. The key conclusion from Table 14.33 is that the highest recovery time is in the winter months as the metocean conditions combine to retain the maximum volume of oil in the sea and the current/wind conditions drive the oil on to the sensitive coastal areas with the highest waterfowl densities.

Table 14.33 Estimated recovery time for waterfowl if it is polluted by oil from an oil discharge from BTC Marine Terminal

Season	Scenario	Amount of Oil	Probability	Area Km^2	% Of Total Bird Area	Total % Of Bird Mortality	Recovery Time	Consequence
Winter	1	5-50	5 %	170	49 %	2 %	Not detectable	**1**
	2	50-500	5 %	180	51 %	10 %	< 1 year	**2**
	3	50-500	5 %	280	80 %	16 %	< 5 years	**3**
	4	>500	5 %	300	86 %	26 %	< 10 years	**4**
Summer	1	5-50	0	0	0	0	Not detectable	**1**
	2	50-500	0	0	0	0	Not detectable	**1**
	3	50-500	0	0	0	0	Not detectable	**1**
	4	>500	5 %	140	40%	12 %	< 5 years	**3**

The total consequence assessment summarised in Table 14.34 that shows that the consequences to waterfowl are highest in the winter period.

Table 14.34 Consequence assessment for VEC 3: Waterfowl

VEC 3: Waterfowl	consequence assessment	scenario	winter	summer	weighting factor
Ecological recovery time	See text and tables above	1	1	1	**50 %**
		2	2	1

		3	2,8	1,6	
		4	3,3	2,6	

14.3.4.4 VEC 4: Sea Turtles

The total numbers of sea turtles are declining worldwide. In the Gulf of Iskenderun, they are particularly susceptible to oil pollution as there are a number of beaches used for nesting during the summer months. Because of this sensitivity, a conservative approach has been taken to the risk assessment using the categories listed in Table 14.35 below. Records from previous oil spill events have shown that the recovery time for nesting beaches can be in the order of less than one year.

Table 14.35 Relation between oil amount and recovery time for nesting beaches

Oil amount per km^2	Recovery time of nesting beaches
<5	Insignificant
5 – 50	< 1 year
50 – 500	1 - 2 year
> 500	2 - 4 year

In this assessment, the consequences are related to two criteria categories: one for the winter months and one for the summer months, which are deemed to be the most sensitive time of the year, as that is when the main turtle nesting period occurs. The consequence values also depend on the percentage of the nesting beaches that are affected by any oil spill.

The categorisation of the consequence values is shown in Table 14.36.

Table 14.36 Categories for consequence values for an oil pollution in the winter and summer half-year

Consequence value	WINTER Percent of nesting beaches in the Gulf of Iskenderun with more than 5% probability for oil pollution	SUMMER Percent of nesting beaches in the Gulf of Iskenderun with more than 5% probability for oil pollution
1	<10%	<1%
2	10-30%	1-10%
3	30-50%	10-30%
4	50-80%	30-50%
5	>80%	>50%

Table 14.37 shows the consequence values due to assessed recovery time and due to percent of nesting beach that has more than 5% probability for oil pollution. The total length of beaches suitable for turtle nesting is approximate 98km.

Table 14.37 Consequence value due to estimated recovery time and consequence value due to size of area with more than 5% probability for oil pollution

Season	Scenario	Amount of oil	Probability	Recovery time	Consequence	Length of Beach	% of Total Beach	Consequence
Winter	1	5-50	5 %	< 1 year	1	9	9 %	1
	2	50-500	5 %	1 - 2 year	2	28	29 %	2
	3	50-500	5 %	1 - 2 year	2	30	31 %	3
	4	>500	5 %	2 - 4 year	3	37	38 %	3
Summer	1	5-50	5 %	< 1 year	1	1	1 %	1
	2	50-500	5 %	1 - 2 year	2	22	22 %	3
	3	50-500	5 %	1 - 2 year	2	30	31 %	4
	4	>500	5 %	2 - 4 year	3	58	59 %	5

The total consequence value in Table 14.38 shows that, for the Green turtle, the highest consequence of oil pollution is if the pollution occurs in the summer.

Table 14.38 Consequence assessment of oil impact on Green turtle beaches

14.3.4.5 VEC 5: Sea mammals, Monk Seal

The main area for Monk seal in the Mediterranean is the Aegean Sea and the Levant Sea south to the area between Cyprus and Mersin bay. Even though Monk seal have been observed from time to time in the Gulf of Iskenderun, it is clear that this is outside of their normal area. The probability of any impact to Monk seal in case of oil pollution, within the Gulf of Iskenderun, is very low. However, focus has to be put on impact and consequences to the Monk seal in relation to accidental oil discharge from transport vessels in the sailing lane to and from the BTC Marine Terminal. This task is outside the scope of this ERA, but it is strongly recommended to also carry out an ERA for the ship sailing lane. There is a commitment to undertake this work and it will be included in the Oil Spill Response Planning Schedule.

14.3.5 Environmental risk

The results from the assessment of Environmental Consequences Values (CV) are taken from the consequence assessment tables in the previous section and summarised in Table 14.39.

Table 14.39 Summary of the assessment of consequence values for oil spill scenarios 1-4

			VEC 1	VEC 2	VEC 3	VEC 4
Season	**Scenario**	**Frequency**	**Fish and fisheries**	**Saltmarshes**	**Waterfowl**	**Green turtle**
Winter	1	1,26E-02	1,5	2,3	1,8	1,8
	2	2,35E-04	1,9	2,9	2,3	2,3
	3	2,07E-04	2,4	3,6	2,8	2,6
	4	4,50E-06	2,6	3,7	3,3	2,8
Summer	1	1,26E-02	1,5	1,8	1,6	1,8
	2	2,35E-04	1,9	1,8	1,6	2,6
	3	2,07E-04	2,4	1,8	1,6	2,8
	4	4,50E-06	3,1	3,2	2,6	3,3

The consequence values for each VEC, with related scenario and frequency, have been sorted in ascending order. The consequence values have been related to a cumulative frequency in the way that the highest consequence value is related to the frequency of the scenario that causes the high value. The frequency for the next consequence value is the sum of the frequency for the scenario with the highest consequence value and the frequency of the scenario related to the consequence value. For each consequence value the frequency for all higher consequence values are added to the frequency for the actual consequence value. An example of how the cumulative frequency is calculated is given in Table 14.40.

Table 14.40 Example of calculating the cumulative frequency for a VEC

Season	**Scenario**	**Frequency**	**Fish and Fisheries**	**Cumulative Frequency**
Winter	1	1,26E-02	1,5	2,61E-02
Summer	1	1,26E-02	1,5	1,35E-02
Winter	2	2,35E-04	1,9	8,93E-04
Summer	2	2,35E-04	1,9	6,58E-04
Winter	3	2,07E-04	2,4	4,23E-04
Summer	3	2,07E-04	2,4	2,16E-04
Winter	4	4,50E-06	2,6	9,00E-06
Summer	4	4,50E-06	3,1	4,50E-06

The environmental risk in terms of cumulative frequency for the consequences for all VEC are shown in Figure 14.11. Frequencies above the black stippled line indicate that the environmental risk is considered to be reasonably high, without taking into account the effect of any risk reducing measures (including oil spill contingency). The results show that the frequency for the consequence values for VEC 2 (Saltmarsh), is higher than for the other VEC. This signifies that the saltmarshes in Yumurtalik Lagoon has the highest environmental risk due to operation of the proposed BTC Marine Terminal. Yumurtalik Lagoon is also important for the waterfowl VEC and partly for the fish and fishery VEC.

This implies that the Yumurtalik Lagoon is a very sensitive and vulnerable for oil spill from the oil export terminal. The dominating wind direction in the winter half-year makes oil drift south- southwest and possibly into the Lagoon. In contrast, the predominating winds in the summer half-year, tends to press the oil further in to the Gulf of Iskenderun and thus the probability of oiling the sensitive areas of Yumurtalik Lagoon is much lower.

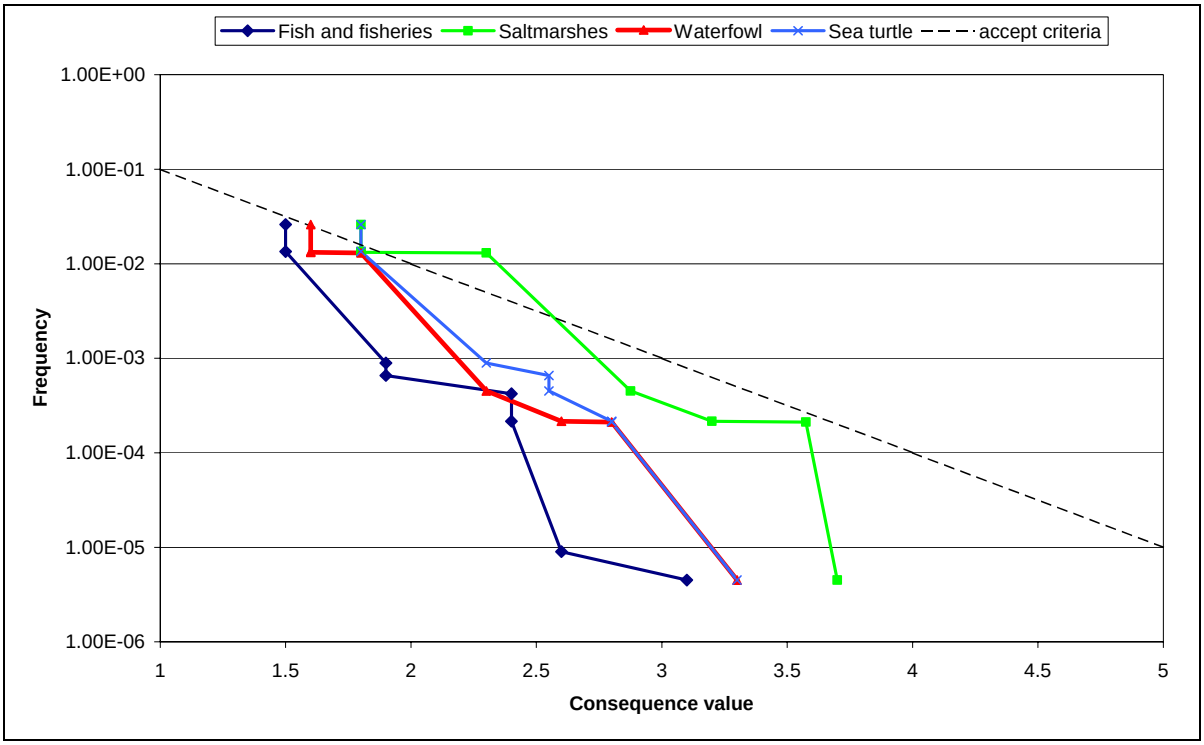

Figure 14.11 Environmental risk related to the BTC Marine Terminal

The stippled line in Figure 14.11 indicates tentative limit for acceptable risk. [Ref 1]

14.4 TRANS-BOUNDARY ISSUES

14.4.1 Introduction

14.4.1.1 The relevance of an assessment of transboundary impacts

Trans-boundary impacts in the context of the proposed BTC Marine Terminal are limited to marine impacts from major oil spills. The Espoo Convention (*The Convention on Environmental Impact Assessment in a Transboundary Context, held at Espoo, Finland*) commits its signatories to carrying out environmental impact assessment on any proposed activities that are likely to cause significant adverse transboundary impact, and to inform and consult the neighbouring countries affected. Although Turkey is not a signatory of the convention, good EIA practice recommends the assessment of significant trans-boundary issues, which are considered further below.

14.4.1.2 Objectives and scope

Section 14.3 presents an environmental risk assessment associated with accidental oil spills which occur within the operational zone of the BTC Marine Terminal. This Section 14.4 presents a consequence assessment, focusing on potential transboundary impacts associated with major accidental oil spillages at sea.

This section comprises a summary of a more detailed oil spill modelling study for tanker accidents outside of the proposed BTC Marine Terminal operational zone, but within Iskenderun Bay. The full study is appended to this EIA Report as Appendix B4.

14.4.2 Spill modelling

14.4.2.1 General Approach to Spill Modelling

Oil spill trajectories have been modelled to simulate slick behaviour in the unlikely event of a major spillage. The simulations have been carried out using the OSIS computer-modelling programme. The model combines oil properties with the environmental conditions of tidal currents, winds and sea state, and air and sea temperature to provide an estimate of the spill's trajectory and its weathering and dispersion behaviour.

It is important to note that the oil spill modelling outcomes make no allowance for any pollution response action, notably the application of dispersants. Also the volumes and location of the spills depict the absolute worst-case scenario, ie adjacent to the Yumurtalik Lagoons, which are recognised nationally as a Nature Reserve and internationally as an Important Bird Area (IBA).

14.4.2.2 Metocean data inputs to model

Meteorological data were obtained from the Yumurtalik Meteorological Station. The annual windrose is illustrated in Figure 14.12.

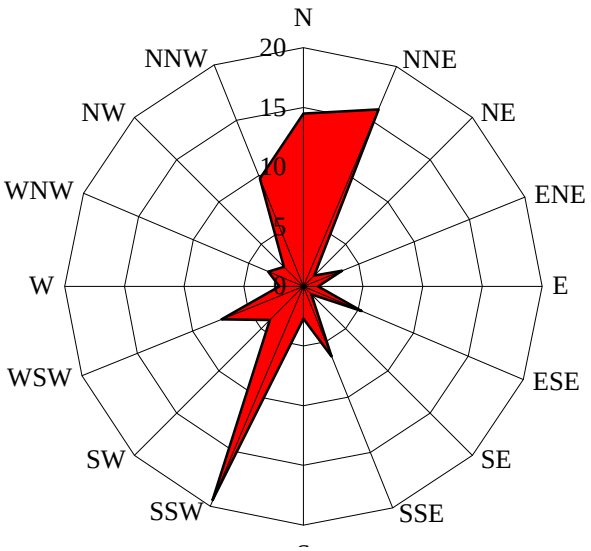

Figure 14.12 Annual Wind Rose (Yumurtalik Meteorological Station, 1996)

For the majority of the year light winds blow from a northeasterly direction, averaging 1.5-2.0 m s^{-1}. The wind direction changes to a westerly direction in April. During the summer months (from June through to September), the prevailing wind direction is south-to-south

west. Wind speeds increase to a brisk 2.1-4.3 m s^{-1} in the summer months, before reverting back to a northerly direction in the winter.

The residual current in the Gulf of Iskenderun indicates distinct seasonal patterns, with a weak flow (0.05 ms^{-1}) in the winter, but a stronger current (0.18 ms^{-1}) in the summer.

14.4.3 Oil weathering process

Oils can be classified into groups according to their overall persistence in the marine environment. Estimates can subsequently be made of their rate of removal from the sea surface. An example of such a classification system is shown below in Figure 14.13.

The figure shows that the volume of Azeri crude oil spilled at sea may increase dramatically soon after it is spilled, as it absorbs water. Subsequently, the slick will break down but 5-10% may persist for a week or more. Box 14.2 shows typical hydrocarbon densities.

Box 14.2 Typical Hydrocarbon Densities

Group	Density	Examples
Group I	Less than 0.8	Gasoline, Kerosene
Group II	0.8 – 0.85	Gas oil, Abu Dhabi Crude
Group III	0.85 – 0.95	Arabian light crude, North Sea Crude Oils, Azeri Crude
Group IV	Greater than 0.95	Heavy fuel oil. Venezuelan Crude Oils

The weathering behaviour of Azeri crude oil has previously been examined through a series of laboratory-based tests designed to replicate the at-sea behaviour (Davies, 2001). That study identified the following key characteristics for the oil.

- Fresh Azeri crude oil is a light oil, with a viscosity of 30 mPas at 27°C and 310 mPas at 6°C.
- The oil readily takes up water to form stable emulsions, with a final water content of 82%. The volume of emulsion on the sea surface can, therefore, be 4-5 times greater than the volume of crude oil spilt.
- After a few hours at sea, the oil will lose 20% by volume through evaporation and the viscosity of emulsified oil ranges from 2,900 mPas at 27°C to 10,500 mPas at 6°C.
- Over periods of 1-2 days, approximately 32% of the oil will be lost by evaporation and the viscosity of emulsified oil increases to 5,800 mPas at 27°C and 31,200 mPas at 6°C.
- Due to the high viscosity of the emulsified oil, spills of Azeri crude oil can be expected to persist for periods of many days on the sea surface.

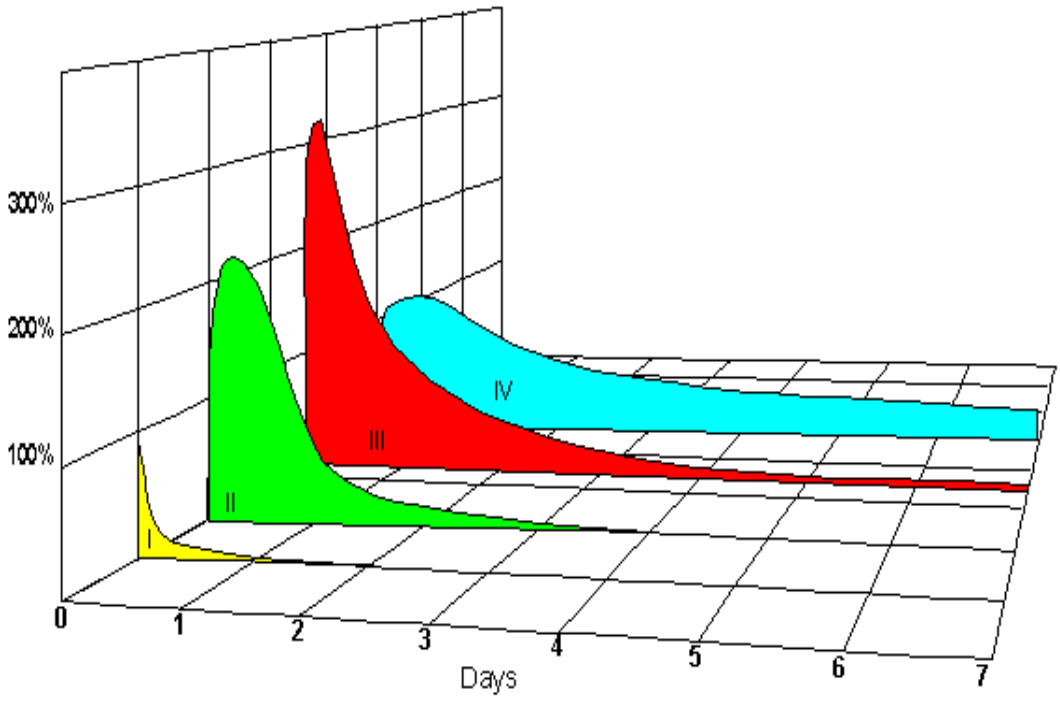

Figure 14.13 Rate of Removal of Oil from the Sea Surface According to Type

14.4.4 Potential transboundary impacts

14.4.4.1 500 tonne spill

The following potential trans-boundary impacts have been identified:

During the winter months the higher wind speeds increase the probability of an oil spill travelling beyond the Bay. During northerly winds, a >500 tonne spill could beach on the northern and eastern coasts of Cyprus or along the coast of Syria. The volume of emulsified oil beaching on these coastlines ranges from 8,000 to 20,000 m^3. The slick would take 3 to 4 days to reach the northern part of the Syrian coastline.

Spills under high wind speeds during the winter will persist for many days. Under Force 8 conditions, the surface oiling diagram indicates that the remote possibility of the spill persisting for long enough to reach the coast of Egypt, near the Ramsar site at Lake Burullus. A total volume of 1,500 m^3 of emulsified oil is predicted to beach 300 hours after the initial release. However, this event is considered to be largely an artefact of the modelling process, as explained previously.

As with the winter scenario, strong northerly winds could carry an oil slick out of the Gulf and onto the coast of Syria during summer months. The time that elapses before beaching occurs ranges from 65–140 hours, depending on wind speed. The volume of emulsified oil impacting on the coastline ranges from 240–112m^3.

14.4.4.2 10,000 tonne spill

The spill model results indicate that oil from a catastrophic spill could beach on the coast of northern Cyprus or along the coast of Syria. The volume of emulsified oil that may end up on these beaches ranges from 8,000 m^3 to 20,000m^3, depending metocean conditions. The slick would take 3-4 days to reach the northern part of the Syrian or Cypriot coasts.

Under Force 8 conditions, the spill may persist sufficiently for 1,500 m^3 of emulsified oil to reach the coast of Egypt (near Lake Burullus), 300 hours after the initial release. As with the smaller spill scenarios, this must be viewed essentially an artefact of the model. In reality, northeasterly winds are unlikely to persist for sufficiently long to drive the slick past the Levantine coast near Haifa.

During the summer months a 10,000 tonne spill is highly likely to remain principally within Iskenderun Bay. The likelihood that oil would leave the Bay is relatively low, whereupon it may pose a threat to the coasts of Syria.

Figure 14.14 depicts the probable trajectory of a 10,000 tonne release of crude oil following a major tanker accident in winter from a point approximately 3km offshore Iskenderun Bay.

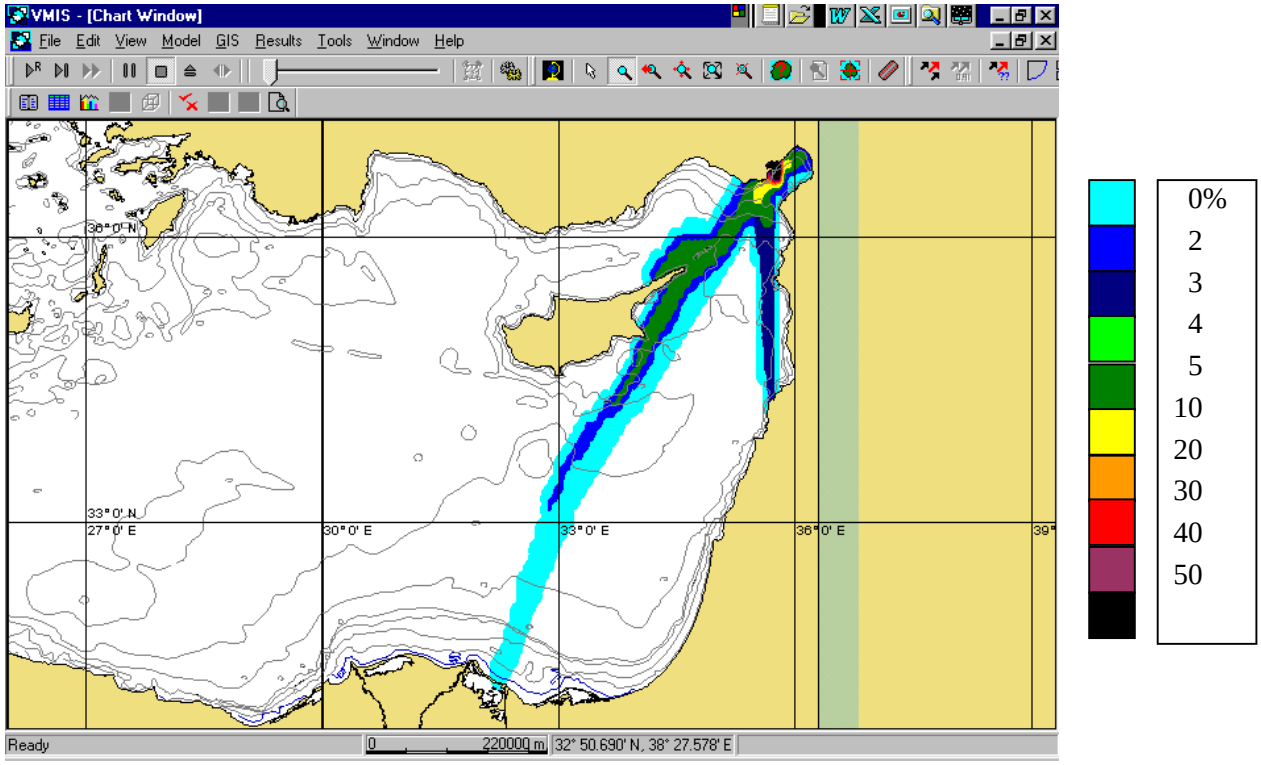

Figure 14.14 Probability of Surface Oiling, 10,000 tonne release of Azeri crude oil, winter

14.4.5 Consequence of transboundary spills

As previously stated, a consideration of the key receptors of potential spill scenarios is required in order to ascertain the risk to the environment of a given scenario. Accordingly, an analysis of the frequency of initiating even and the probability of the required metocean conditions occurring has been used to determine the frequency of incidents resulting in trans-boundary impacts. In addition, specific sensitivities known from each of the impact locations have been noted in order to understand more fully the consequences of these scenarios (see Table 14.41). This information will feed into the development of a specific oil spill response plan (OSRP) to be devised during ongoing detailed design and construction phase.

Table 14.41 Consequences of Transboundary Scenarios

Spill scenario	Wind conditions	Impact	Time to Beaching (days)	Amount (approx)	Specific Sensitivities
500 te Winter	Northerly	Lebanon	9 – 10	150 m^3	Tourism
	North-easterly	North and East Cyprus	4 – 5	300 m^3	Monk seal, green turtle, tourism
500 te Summer	Northerly > Force 4	Syria	2.5-6	240 – 112 m^3	none known
10000 te winter	Northerly Force 8	North Cyprus	3 – 4	8,000 – 20,000 m^3	Monk seal, green turtle, tourism
	Northerly Force 8	North Syria	3 – 4	8,000 – 20,000 m^3	none known
	Northerly Force 8	North Egypt	12-13	1,500 m^3	Lake Burullus Ramsar site
10000 te summer	Northerly > Force 4	North Syria	2.5-6	8,000 – 20,000 m^3	none known

14.5 INCIDENT RESPONSE

14.5.1 General framework

BTC recognises that an integrated approach to oil spill preparedness and response is required to minimise the risk of a spill and the potential environmental damage from a spill. The framework for the development of the OSRP has been developed as part of the preliminary work programme to address the following:

- Ensuring appropriate emergency response resources and procedures are in place;
- Ensuring appropriate training is undertaken.

The aims and objectives of the proposed BTC OSRP will be to provide the means to:

- Control a release which may arise from a fault in the operation of the pipeline and associated facilities;
- Minimise the volume of such releases when they do occur by securing the source in the most appropriate way;
- Minimise the movement from the source of released oil by timely containment;
- Minimise the environmental impact of primary releases by timely containment and recovery response;
- Maximise the effectiveness of such response through appropriate equipment and technique selection. This will be based on full knowledge of the relevant properties of the oil and the changes in their properties arising from the ambient conditions into which they are released and the sea and land conditions and morphologies onto which they are released;
- Maximise the effectiveness of the response through trained and competent operational and response teams.

For each country in the BTC system (Azerbaijan, Georgia and Turkey) a country specific OSRP will be developed to cover all of the facilities. These OSRPs will not only cover BTC but also other projects operated by the BP Baku Business Unit. The contents of the OSRP will include:

- Response and organisation;

- Notification and callout procedures;
- Contact details;
- Roles and responsibilities;
- Risk assessment;
- Response action plans.

Specifically for the BTC Marine Terminal, the existing containment and recovery provision at Ceyhan and the opportunity to incorporate the OSIS model into the future response planning arrangements for the port will be explored.

14.5.2 OSRP concept

To respond effectively to a spill, it is important to appropriately prioritise actions and assign response resources to different incidents. The usual way of achieving this is to define tiers of response, which are related to the size of a spill incident and the availability of resources to deal with it. Definition of a spill event in terms of Tier 1, 2 and 3 have already been used for the existing Azerbaijan and Georgia OSRPs. The existing OSRP definitions are set out below:

- **Tier 1 event**: A small local spill requiring no outside intervention and can be dealt with on site by local staff and stockpiled equipment; ie dedicated resources available at the CMT.

- **Tier 2 event**: A larger spill that would require additional outside resources and manpower, such as an oil spill response contractor, or co-operative action between local operators, eg utilising resources from Iskenderun and Dortyol.

- **Tier 3 event**: A large, possibly ongoing spill, which will require additional regional and possibly international resources. Such spills are very rare (as discussed above) and would only occur through full diameter pipe rupture, storage tank collapse or a major tanker incident such as collision with another vessel. The clean up for a Tier 3 event will utilise all BTC manpower and resources, and be augmented by additional resources from external resources such as Briggs Marine Environmental Services (BMES) in Baku or other Tier 3 contractor and/or Oil Spill Response, Ltd (OSRL) from Southampton, UK, or the East Asian Response Ltd (EARL) in Singapore.

One of the key purposes of the OSRP is to provide, as far as possible quantitative measures for the various tiers for each component of the Project. In addition, each tier of response will have associated operation details, such as:

- Roles and responsibilities;
- Contact numbers list;
- Mobilisation of appropriate external response (eg Oil Spill Response Ltd (OSRL)) in the event that an oil plume may impact on territories in which no OSRP capability or Inter-Governmental agreement exists;
- Containment Plans (ie identification of containment locations inside the Azerbaijan border to ensure a spill in Georgia can be appropriately contained when it crosses).

14.5.3 Recommendation for risk reduction and oil spill contingency

Storing, loading and transport of large quantities of oil will always be associated with a risk of accidental events, despite the fact that the operators continuously seek to improve the

technological, operational and organisational elements so that the safety level of the operations are improved. This safety and risk management process involves all aspects of the operation; both personnel, assets and the environment. Many of the general recommendations for risk reduction are incorporated in other areas, only recommendations based on the results from the ERA are outlined below.

Area of highest risk is Yumurtalik Lagoon. The oil spill response plan should include methods to avoid oil from entering the lagoon. The highest probability for oil pollution in the lagoon is in the winter period.

The oil preparedness plan must, among other, take into consideration the following parameters:

- Response time: 1 day. The fastest drift time of oil from the terminal to the Yumurtalik Lagoon is 1.9 days.

- Capacity: average emulsified oil within the outer part of the Lagoon is estimated to be ca 4700 tonnes for a medium spill, ca 11000 tonnes for a large spill and ca 49500 for a very large spill.

- Oil spill combating near the source is the best option. Especially for this case where sensitive environmental resources are situation close to the terminal.

- Use of oil dispersants must be carefully elucidated, especially regarding shallow fish spawning sites in the summer half-year.

14.5.4 Linking the EIA to the OSRP

As detailed above, an assessment has been undertaken to understand the possible spill scenarios that could be expected from the BTC Marine Terminal operations. The assessment is considered conservative as it is based on historical data and does not take into consideration improvements in design techniques or asset management methodologies.

Notwithstanding the conservative assumptions made in the risk assessment the outputs will however be very useful in enabling the Oil Spill Response planners to define the appropriate resources that should be employed for the BTC Pipeline. In particular the outputs from this assessment can be used to determine what Tier 2 resources will be required. It will also be necessary to develop different response strategies dependant not only on the probable release size but also on the sensitivity of the environment in the leak location.

For offshore spills, the OSRP will address:

- Means to estimate evaporative losses, emulsification and natural dispersion rates, based on oil properties and exposure times;
- Amounts of released oil requiring containment and removal from the various locations as a function of exposure time;
- Recovery rates (tonnes per hour) likely to be achieved by the selected techniques and equipment;
- Optimisation of response resource provisions as between sea (inland water) and shorelines (river banks).

There will be a number of specific response plans prepared as part of the overall OSRP including response plans for onshore and offshore spills.

The OSRP will establish sufficient response capabilities in each country to enable a moderate to large (7-700 te) incident to be handled using in-country resources. Notwithstanding this, the BTC Owners will continue to consult with the boundary authorities in Azerbaijan, Georgia and Turkey to ensure that appropriate equipment could be moved from country to country in the event of a spill. The OSRP will also address the responses required in the event of an oil spill occurring in one country that could potentially impact another country (as detailed below).

14.5.5 Transboundary response

A catastrophic tanker incident has the potential for major trans-boundary impacts. The OSRP will address the responses required in the event of an oil spill occurring in one country that could potentially impact another country. In the case of BTC Marine Terminal operations, these are Cyprus, Syria, Lebanon, Israel and Egypt. Co-ordination with the Regional Marine Pollution Emergency Response Centre for the Mediterranean (REMPEC) will also be required.

14.6 CONCLUSIONS

The potential impact of an oil spillage to sea depends on the type and quantity of oil spilt, the location of the spill and the sea state and winds at the time of the spill. Major crude oil spills have a very low probability of occurrence, however, if they do occur there is the potential for them to cause pollution with major environmental consequences.

The primary aim is to prevent any spillages occurring and to this end, procedural controls will be firmly in place. An integrated approach to preparedness for oil spill response will be adopted for all aspects of incident management and this will include:

- construction of the Project in a manner that minimises risks of incidents;
- design of the pipeline system and terminal to ensure the risks of incidents during operation are minimised;
- ensuring the pipeline and terminal are operated in a manner that minimises the risk of incidents;
- recognition that incidents may occur and have an understanding of the risks.

The loading of oil tankers and jetties is a well established process and the risks are understood therefore allowing appropriate prevention procedures to be put in place eg addressing the identified risks during the design phase and purchase of equipment as well as ensuring that all personnel are properly trained. As operational procedures are put in place, the OSRP will be aligned with them and with the overall BOTAŞ Emergency Response Plan and the overall Strategy for the BTC Pipeline.

Marine traffic within the harbour will be strictly controlled by the Harbour Authority in accordance with the Ceyhan Harbour Operating Regulation to ensure risk is minimal.

15 SUMMARY OF KEY RESIDUAL IMPACTS

15.1 INTRODUCTION

Sections 6, 7, 11 and 12 of this EIA Report describe the potential environmental and social impacts and benefits that could occur as a result of the construction and operation of the BTC Project, together with the mitigation measures that will be applied to identified impacts.

During the planning and design development of the BTC Project many potential impacts have been completely avoided by design and routing decisions during the Basic and Detailed Engineering phases. Many other potential impacts are minor by virtue of the characteristics of the receiving environment, the nature of the project activity and measures that are an inherent part of good design and good practice. However, not all impacts can be fully mitigated, and residual effects will be experienced by environmental and social receptors. This section summarises residual environmental and social impacts of the BTC Project in Turkey that are viewed as being most important.

It should be noted that some (but not all) of the significant residual impacts described in this section stem in part from uncertainty (in the baseline, in the project intent, in the effectiveness of mitigation and in how the environment and people might respond). Where there is a level of uncertainty and a vulnerable/sensitive/valuable environmental or social receptor, it is appropriate that the EIA be cautious (or adopt what is also referred to as a 'worst case' or 'precautionary principle' approach) in applying the significance criteria. This caution serves to highlight key areas of critical uncertainty so as to ensure that additional actions (over and above those already defined within the available mitigation measures that have been provided for in the impact assessment) are undertaken to manage the implications of this uncertainty. Such additional actions may include increased levels of vigilance and scrutiny during project implementation, additional studies (of the baseline, of engineering techniques, etc) and enhanced level of communication with affected people. The rigorous application, and further development, of the provisions and requirements of the various environmental and social management plans presented in Appendix C (noting that these may in turn be amended to reflect new information obtained during pre-construction surveys), provides a robust means of managing the ongoing environmental and social issues associated with the Project and is critical to the application of the EIA as a powerful management tool throughout the project life cycle.

It should be reiterated, however, that the mechanisms and provisions of the management plans have already been applied to identified impacts during the assessment process and that the residual impacts discussed within this Section are those that remain after the application and maintenance of the requirements of the management plans as they are currently drafted.

For residual environmental impacts, those that are regarded as most important have been evaluated as Moderate and Major. These levels of impact broadly equate to those that have been defined as Significant social impacts. However, the social impact assessment has not distinguished between two levels of significant impacts in the way that the environmental impact assessment has. Box 15.1 provides a further explanation in the context of the ensuing discussion of residual impacts.

Box 15.1 Significant Environmental and Social Impacts

ENVIRONMENT	SOCIAL
Major: these are residual impacts that are judged to be in excess of the thresholds defined in Section 3 for the various environmental aspects despite the planned mitigation which has sought to reduce those impacts to as low as reasonably practicable. Many of these stem from uncertainty in the baseline or over the effectiveness of mitigation combined with conservative evaluation of significance. The basic principles behind dealing with Major impacts described subsequently in this section are to: (a) resolve uncertainty through additional studies; (b) amend mitigation in light of the further studies; (c) implement the mitigation (and monitoring) with an extra degree of vigilance. An extra degree of vigilance for some matters does not imply a lack of it elsewhere. An example would be in certain areas having the work of the on-site Environmental Inspector supplemented by the presence of specialist experts (eg soils scientist, archaeologist, bat expert etc). **Moderate:** these are residual impacts that exceed the thresholds defined in Section 3 despite the planned mitigation, which has sought to reduce those impacts. Whilst some of these moderate residual impacts stem from uncertainty (and may therefore be amenable to further mitigation on the basis of improved information), some will require additional and sustained management scrutiny to avoid major impacts occurring. Their inclusion is intended, therefore, to ensure that ongoing management scrutiny is maintained over these impacts.	In the consideration of social impacts, an impact is defined as either 'Significant' or 'Not Significant'. Ranking the importance of impacts is frequently based on assessment criteria such as duration, geographical extent, probability, number of people affected etc. However, this approach (when assessing social impacts) does not take cognisance of the significance of an impact on the household or individual level. This applies particularly to poorer households who are more vulnerable to social impacts. Thus, where an impact has the potential to leave a household worse off than before, the impact is considered to be significant. However, it is reasonable, based on professional judgement and feedback from consultation, to identify those significant impacts that are considered to be most important. This differentiation is based on the following criteria: **Most important significant impacts:** • impacts where there is uncertainty regarding the effectiveness of mitigation; • impacts that were targeted as key areas of concern during the consultation process; and • impacts that require additional studies in order to more fully understand the nature of the impact and devise refined mitigation measures. **Other significant impacts:** these impacts are still important, but there is a higher degree of assurance that mitigation will be effective.

This EIA Report represents the Project's status at Draft EIA disclosure. Although major environmental and significant social residual impacts have been described in the EIA, in this Section guidance is provided on the range of additional mitigation measures (including the development of additional management provisions, the collection and utilisation of stakeholder feedback, the commissioning of further studies etc) that might be required during Project implementation in order to avoid impacts at these levels of significance. The future, ongoing management scrutiny, impact monitoring and process auditing that is provided for within the EMMP and the supporting environmental and social management plans, will determine the degree to which these additional opportunities for impact reduction have been taken.

15.2 RESIDUAL IMPACTS ALONG THE PIPELINE

15.2.1 Residual environmental impacts of Major significance

This section describes the residual environmental impacts evaluated as Major. Major residual impacts could potentially occur for soils, landscape, ecology and noise at various locations along the pipeline. As stated above, the evaluation of Major impacts stems in part from uncertainty factors and a precautionary approach to impact assessment. The following subsections have identified means and mechanisms, therefore, by which uncertainty will be addressed and managed. In the majority of instances, if not all, these measures should ultimately ensure that the residual impact becomes Moderate.

15.2.1.1 Soils

The EIA has identified the need for the appointment of a soil expert to provide ongoing advice on the management of residual soil impacts during the construction and reinstatement phases of the BTC project.

The residual impacts associated with different soils are discussed below.

Soils - tuff

Pipeline construction on mesic coarse-loamy Entic Dystrandept soils wherever tuff dominates the landscape, will potentially give rise to Major residual impacts between KPs 0 – 10, 16 – 45, 85 – 137, 156 – 171 and 192 - 238. According to the criteria in Section 3 these impacts could be of regional extent given their repetition along the corridor. The impacts are reversible through both management intervention and natural recovery so, while they may extend beyond the short-term, they will not endure throughout the project lifetime.

At this stage, there is a degree of uncertainty in the assessment that stems from the precise nature of soils on the working width (assessment was largely based on data collected for the 500m corridor) and how these soils will respond to reinstatement. These issues and project actions to resolve them are discussed below.

While it may not be possible to reduce major impacts to moderate ones everywhere the measures described should be able to both localise the impacts more and reduce their duration.

Tuff is volcanic ash. It occurs as broad, white - or grey-coloured sheets that, once disturbed, erode into angular, craggy outcrops and deep canyons. Its fertility is comparable to powdered glass. Tuffaceous lands occur in northeastern Turkey, where they support a low-density coniferous forest underlain by xeric shrubs and coarse grass. Such soil has inherently low productivity and is difficult to reinstate due to lack of depth, leaving the whitish tuff exposed and mixed with the original topsoil. Reduced soil productivity and increased rates of soil erosion constitute the main potential impacts (along with indirect impacts to landscape – see below), which will be mitigated as far as practicable through application of reinstatement specifications described in the impact tables in Section 6 and the Reinstatement Plan (RP) (see Appendix C2). However, despite the application of these mitigation measures there will be a Major residual impact as soils developed from tuff are unlikely to respond to standard reinstatement and exposed tuff and its effects on soil productivity will continue throughout the duration of the Project.

Mitigating the impacts of pipeline construction on tuff will require an additional narrowing of the construction corridor to as small a width as possible. This is feasible because the topsoil is so thin that it will occupy little space when reserved during trench excavation. However, careful management of reserved topsoil will be required as tuff topsoil is the sole reservoir of fertility in tuffaceous soils and an important store of seeds. Since the topsoil is thin and variable in depth it is inappropriate to specify to contractors a prescriptive thickness to be removed. If the thickness is too great the outcome will be that topsoil will be removed together with subsoil of near-zero productivity. When they are returned the two could be mixed and the overall productivity substantially reduced before reinstatement even starts.

To address these issues will require pre-construction surveys and close supervision during construction and reinstatement, both involving expert soil scientist input employed specifically for such work. Topsoil thickness will therefore be established at regular intervals. Intervals will vary and will be decided by a soils expert. The soils expert will also establish the topsoil depth and discuss the most appropriate removal technique with the construction contractor. The Project's Contractors will set aside shrubs and coarse grasses for replanting. On a strip of some length, if possible, replanting materials will be removed and replanted along a length of the RoW with the same soil and soil climate conditions and where reinstatement is nearing its end. Temporary soil erosion control measures will be established while constructing the pipeline. These will include temporary water bars, ditch breakers, and runoff barriers such as filter fences or straw bales.

The land will be returned to as close to its natural contours as practicable. The infilled subsoil will be returned in layers following the same sequences as its removal. A crown no higher than 0.3m high will be left to allow for eventual settling of the soil. The resulting surface will then be profiled to conform to slope breaker and other specifications. Slope breakers will drain into a cuvette sculpted into the soil at each slope breaker outlet. Only then will the topsoil be replaced. If the growing season is nearing its end, the on-site soils expert may require the topsoil berm to be seeded with a fast growing cover crop, when it will be stored for spreading the following spring.

Vegetation will be replanted accompanied by a basal dose of fertiliser mix. On tuff the usual 10-10-10 application of NPK will require additional micro-nutrients. Local expert advice will be sought from the Ministries of Forestry and Agriculture. Plants in addition to those recovered during topsoil stripping will likely be required if reinstatement is to succeed. Again, expert local advice will be sought in identifying seed or plant sources.

East Anatolian Natural Gas Pipeline (NGP)

From KPs 259 to 546, existing soil related liabilities of the NGP, which was not adequately reinstated, would be potentially exacerbated by the BTC Pipeline, where their RoWs lie adjacent or closely parallel.

It is a project requirement that the BTC Pipeline will not inherit the reputation and soil erosion problems caused by poor reinstatement of the NGP. Therefore, a two-phase approach to reinstatement in the vicinity of the NGP will be adopted, which is more fully described in the Reinstatement Plan (RP) (see Appendix C2). Briefly, phase one will entail the NGP construction contractor undertaking remedial reinstatement measures prior to BTC Pipeline construction to resolve existing problems and phase two will require the BTC Contractor to undertake any additional mitigation measures to ensure the integrity of the BTC corridor in areas impacted, or potentially impacted, by the presence and/or proximity of the NGP pipeline. Special areas identified as requiring specific reinstatement measures prior to, or during, reinstatement of the BTC Pipeline are as follows:

- general reinstatement;
- adjacent agricultural land – for example, in areas of poor topsoil management;
- hill slope reinstatement – for example, installation of slope breakers across entire parallel corridors;
- erosion – for example, in areas of rill and gully development;
- river crossings – for example, bank and bed erosion.

Responsibilities between the NGP and BTC Contractors are described in the RP (see Appendix C2).

Soils - marl on hills, plateaux and plateaux scarps

Marl is calcareous clay that classes as a soft rock. It occurs throughout the Mediterranean basin and its environs, where it supports a productive, rainfed agriculture. It is susceptible to subsurface piping in which runoff rapidly infiltrates to flow along regular conduits deep in the soil. These occasionally enlarge sufficiently to emerge onto the land surface as ravines. It typically has a thick, dark brown topsoil. Its erosion under agriculture can be intense. The topsoil is made up of a residuum of impurities, such as silicates and iron from the primordial earth; approximately 400m of marl must dissolve and erode to create 1m of topsoil, in effect the persisting impurities retained by the surface. The current pale colour of topsoil found in central Anatolia results from its having been mixed into the subsoil by millennia of tillage; erosion has expanded since the advent of mechanised agriculture, so that the present soil is much reduced from its early profile.

Marl occurs as hills, plateaux and plateau scarps, and plains. Plains soils are classed as agricultural lands. Marl soils that are too steep to play a role in rainfed agriculture, although they may support grazing, are generally present between KP 617 - 647. Adverse impacts affecting marls including the following:

- visual impact: the marl leaves a whitish trace across the landscape where the subsoil has been exposed;
- soil erosion: marl erodes easily – in areas near Turkey's coast marl can rotate as deep landslides;
- loss of soil productivity.

Marlacious hills are important to the Turkish economy, where they support uses such as grazing, wildlife habitat, beekeeping and watershed management.

According to the criteria in Section 3 these impacts will be of local extent. They are reversible through both management intervention and natural recovery so while they may extend beyond the short-term, in the longer term they will reduce to a moderate level for much the same reasons as were described above for tuff.

As with tuffaceous lands, an important mitigation will be to reduce the construction corridor to as narrow a width as possible. This is possible because marly topsoil on sloping lands is typically thin and requires little area when set aside for reinstatement. Existing shrubs will be set aside for later replanting. Temporary soil erosion control measures (water bars, ditch breakers and runoff barriers) will be installed. Temporary ditch breakers will be particularly important as marls typically contain springs that are likely to drain into the trench from the middle two-thirds of most slopes. When drained, trench water will be pumped either into a filter bag or constructed barrier made of baled hay/straw and filter cloth; in no instance will it

drain onto unprotected soil. In some instances, emerging springs may require lined chutes to convey water from the right-of-way to a safe disposal location.

The specifications for returning tuff to its natural contour and condition also apply to marl and similar considerations to tuff will be applied as regards use of a soils expert and tailoring topsoil removal to the actual thickness present rather than a pre-prescribed specification.

The potential for replanting will be determined by the frequency of natural vegetation prior to construction. If this is low or absent, then replanting is unlikely to succeed – the onsite environmental inspector/soils expert will give a judgement as to the treatment that might be applied, eg mulch ratios, jute matting, etc. In areas where the site is incapable of supporting sown grass or other vegetation, even in the short term, mulch and jute matting will be used to prevent erosion and facilitate growth. Again, the onsite environmental inspector/soils expert will give a judgement to be fulfilled by the construction contractor. If replanting is to be done, it will follow project specifications using a grass mix recommended by local agricultural and forestry expertise. If the season is too late for replanting, the topsoil berm will be protected over winter by seeding it with a fast growing cover crop. It will then be reinstated during the following spring.

Soils - marl on rainfed agricultural lands

Central Anatolia lies near the origin of western rainfed cereal production. Its soils have been tilled for at least five millennia and offer a promising future for continuing production. With care, their condition is likely to improve through the eventual introduction of such practices as no- and low-till agriculture.

As with marly soils, centuries of tillage have so thoroughly mixed the topsoil with underlying layers that much of its distinctive character has reduced through time. Annual tillage has erased traces of soil erosion, presenting a surface largely undisturbed by gullies and rills. This is not entirely accidental. The practice of tillage and seeding prior to the onset of winter rains increases infiltrability, so that a crop surface is already well established before the advent of snowmelt and spring rains. Pipeline construction in valley bottoms between KP 617 and 747 will potentially interrupt this natural sequence of the agricultural calendar, although not necessarily at all locations along this stretch. Potential adverse impacts to rainfed agricultural lands include the following.

- increase of rainfall- and runoff-caused soil erosion;
- increase of sediment and turbidity;
- reduced soil productivity.

According to the criteria in Section 3, these impacts will be a series of major, short-term localised impacts confined to valley bottoms. However, their repetitious nature will lead to impacts at a regional scale. The Reinstatement Plan (see Appendix C2) sets a requirement for arable land (that will address the majority of the impacted areas described here) to be left in a condition suitable for re-planting with crops. Impacts are therefore reversible, and beyond the short-term will be moderate to minor and localised.

Many of the practices described in the previous sub-section apply equally well to rainfed agricultural lands. An important difference, however, will be an intensification of direct consultations between the Project and the farmer. Under such circumstances, the works will be discussed with each landowner and his needs will be incorporated into the construction programme and methods. It is intended that the farmer will play a signatory role in determining whether outstanding issues have been closed out, and whether or not the reinstatement complies with his wishes.

15.2.1.2 Landscape and visual

From the Georgian border to KP 18, there will be a local, major visual impact where the pipeline exposes whitish tuff parent material. This impact will extend beyond the short-term but will be reversible according to the degree of success of the soil reinstatement and recovery. The impact will be mitigated as far as practicable through application of reinstatement specifications described in the impact tables in Supplement 1 of Volume 2 and the RP. However, this will be a major residual impact as standard reinstatement is unlikely to be fully effective where corridor overlies tuff, which will retain its whitish colour and show as a white line across the landscape, particularly in the hills around Posof.

The formation of a conspicuous whitish line across the landscape is also predicted where pale-coloured sandy-skeletal Cryochrept soils overlying tuff or parent material in low-lying areas are exposed during construction between KPs 18 to 40, KPs 100 to 115 and KPs 154 to 197. This will result in a major residual impact where standard reinstatement is unlikely to be fully effective where the Right of Way (RoW) overlies tuff, which will retain its whitish colour and show as a white line across the landscape. The scale of impact declines south of KP 40 and is expected to be moderate to major between KPs 178 and 197 as visibility will depend on the precise location and character of the landscape and the impact is anticipated to be less pronounced in more intensively farmed and vegetated areas. However, the impact will be regional on the basis of its repetition through several landscapes.

As the land rises into the Allahuekber Mountains between KPs 115 and 134, the greater diversity of landform and land cover enhances the visual interest of the scenery and increases its sensitivity to change. Exposure of parent materials along this section of the route will create a highly visible strip, which will be mitigated to some extent on affected grasslands by implementing fertiliser trials using NPK and micronutrients on reinstatement species. However, a major residual impact will still result in this area as standard reinstatement is unlikely to be fully effective where the RoW overlies tuff, which will retain its whitish colour and show as a white line across a highly exposed landscape. This impact will persist in the short to medium-term (from one growing season up to five or six years thereafter) across shallow-soiled grasslands in areas of remote character.

15.2.1.3 Ecology

Botanical species of significant conservation value are present in many sections of the pipeline route. Moderate localised impacts to habitats/flora will occur in sub-alpine meadows found along the following sections: KP0-34; 50-86; 134-178; 484-525; 832-849. Since these impacts will be repeated at several locations across several provinces they can be viewed as being of provincial-national scale in their extent.

However, the impacts are also reversible, so while they may extend beyond the short-term, mitigation will ensure that in the medium term (perhaps 3-5 years), local impacts will reduce to minor and the regional/national extent of impacts will be moderate at most. Key mitigation measures will include:

- pre-construction surveys feeding into site-specific reinstatement plans (see Reinstatement Plan, Appendix C2);
- employment of botanical experts to provide on-site advice and supervision;
- programming works through environmentally sensitive areas to achieve a target of three weeks between topsoil stripping and commencing reinstatement;
- where appropriate, transplantation of certain species.

Areas of particular sensitivity, where moderate impacts are predicted, are further discussed in Section 15.2.2.4.

In order to compensate for the residual ecological impacts associated with the construction of the pipeline and its associated facilities, the BTC Co is committed to an Environmental Investment Programme (EIP), which includes a specific commitment to undertake compensatory habitat creation. Whilst the recreation of some of the complex habitats impacted by the pipeline will prove infeasible (at least in the short term), the commitment does provide a mechanism and resourcing for off-set compensatory measures to be pursued.

15.2.1.4 Noise

The nearest edge of the settlement of Yaylakent in Erzincan Province is located approximately 26m from the centreline of the pipeline. Major short-term noise impacts are expected to occur during all phases of construction at Yaylakent, due to the proximity of the settlement to the pipeline route, although the application of mitigation measures will reduce the potential for disturbance for some phases.

The settlement of Pirdede (Imranli District, Sivas Province) is located approximately 86m from the centreline of the pipeline and is also located adjacent to a crossing of the NGP. Residents in close proximity to working areas will experience similar impacts to those described above. Pirdede is also located within 100 m of piling activities, so vibration impacts could also occur at the nearest properties.

Similar short-term noise impacts are also expected to occur at Keklikoluk (Goksun District, Kahramanmaras Province) during all phases of the pipeline construction and at Mehmetbey (Goksun District, Kahramanmaras Province) during soil stripping, welding/lowering, backfilling, bending and trenching. Blasting works will also give rise to noise and vibration at Keklikoluk.

Similar short-term impacts will also occur to noise sensitive receptors at Kastal (approximately 99 m from the centre of the pipeline and close to a provincial highway crossing) during soil stripping, welding/lowering and backfilling, and during excavation and piling works associated with the highway crossing. Blasting will also give rise to noise and vibration at Kastal.

In addition to all the noise mitigation measures listed in the EIA, in all instances stockpiling of spoil and purpose-built mobile noise barriers will be used to screen nearby dwellings from the construction works to the maximum extent possible. However, for the communities mentioned above, those residents nearest may still be exposed to temporary construction noise levels that exceed 70dB(A). This is based on a conservative assessment that took a noise source to receptor distance as being from the nearest edge of the community to the nearest edge of the construction corridor. To address this uncertainty, the pre-construction programme will therefore make provision for a further assessment (as part of the EMMP) based on the true numbers of receptors affected and accurate separation distances of receptors from noise sources, taking whatever actions are necessary to reduce impacts to an acceptable level. These actions may comprise additional physical barriers to attenuate noise. Alternatively mitigation could comprise compensation through the provision of alternative accommodation for affected residents during certain construction phases.

15.2.2 Residual environmental impacts of Moderate significance

15.2.2.1 Soils

Pipeline construction on soils between KPs 50 to 68 and KPs 610 to 766 will give rise to moderate impacts as soil erosion will be visibly active but with no rill and gully formation evident. These soil types include calcareous soils occupying gently sloping and sloping lands, flood-plain soils, reddish-coloured soils on shallow slopes on valley bottoms, mesic clayey-skeletal shallow xerochrepts on plateau scarps and mesic loamy-skeletal xerochrepts on sloping uplands, which are highly eroded on the scarp.

Mitigation measures to control soil erosion in these areas will comprise the application of a number of environmental specifications described in the Reinstatement Plan (RP) (see Appendix C2), including topsoil removal and storage, subsoil removal and storage and reinstatement of soils; permanent erosion control devices; sediment interception and sediment settling ponds where required by the landowner/occupier; bio-restoration and channel stabilisation.

From KP 291 to 298, impacts will occur on mesic soils on the scarp, as it will be difficult to reinstate to its pre-existing condition using standard techniques. Careful attention to final routing and use of site-specific innovative reinstatement techniques will ensure that the impacts are moderate at most (see RP, Appendix C2).

15.2.2.2 Landscape and visual

General

Moderate localised landscape impacts are expected as a result of tree loss in the Posof Wildlife Protection Area (WPA). However, as the pipeline has been re-routed to avoid dense broadleaf forest, the residual impact is substantially less than the impact of the previous alignment through this area and has been reduced to as low as reasonably practicable. The route now passes to the west of the previous alignment, through an area of sparser, patchy forest. A reforestation and replanting programme, using species appropriate and characteristic of the area, will be undertaken during reinstatement of the pipeline RoW through the WPA. Residual impacts will therefore extend beyond the short-term but can be regarded as being reversible.

In areas with a high water table on weak soils, (from KPs 18 to 34), moderate localised, short-term impacts are anticipated as a result of storage of surface water after passage of construction in depressions in the soil surface. Measures, such as the use of moveable equipment mats will be required throughout the construction period to support heavy equipment. Once construction has been completed, depressions will be graded out during the reinstatement phase, monitored for signs of settlement and ponding and repaired as necessary. The predicted residual impacts can therefore be regarded as short-term and reversible.

Between KPs 68 to 115, the route crosses the Ardahan Plateau, where landscape sensitivity is moderate. The partly cultivated plateau comprises largely grassland with frequent rocky exposures, and with small streams or rivers flowing through wide flat, often marshy, valleys rich in spring flowers. Moderate, localised impacts extending beyond the short-term will occur in this area, as sections of marshy grassland are likely to show signs of construction for several years. However, measures to reduce the impact of heavy machinery including route narrowing and the use of moveable equipment to spread vehicle weight and avoid deep rutting will be employed throughout the construction period. Furthermore, construction will be

undertaken at the driest time of year (July to August) or, where this is not possible, removal/replacement of turfs where the schedule dictates work during wetter periods (April to June). Impacts can therefore be regarded as reversible.

The rolling terrain between KPs 134 to 154 is punctuated by sections of steep and moderately steep land. Disturbance of soils overlying tuff in this stretch will result in an exposed whitish strip. Despite application of mitigation measures, reinstatement is unlikely to be fully effective where the pipeline corridor overlies tuff, which will retain its whitish colour and show as a white line across a highly visible landscape. Residual impacts will, therefore, be moderate and localised and, whilst they will extend beyond the short-term, the impacts can be regarded as being reversible.

South of KP170 and up to KP 178, the route passes along the edge of two very different but equally scenic landscapes – to the south the broad, wild, rolling mountain pastures and to the north the plunging gorge of the Kuyularin Creek and the arid, angular mountains beyond. Localised, moderate impacts are predicted in mountain pastures as shallow soils may prolong the period for re-instatement to be effective. Whilst residual impacts will be reversible, they will extend beyond the short-term.

The route passes through an area that is quite intensively farmed and with low sensitivity landscape between KPs 197 and 240. Moderate to minor impacts will give rise to the formation of a conspicuous whitish line across the landscape where pale-coloured coarse-loamy Entic Dystrandepts soils developed from tuff or parent material are exposed. Reinstatement is again unlikely to be fully effective where the pipeline corridor overlies tuff, although this would be attenuated by the field tapestry, which would conceal it to some extent and break up any continuity of visible impact. The impact will also be less pronounced in more intensively farmed and vegetated areas. The impact will be localised and reversible and in many places may not extend much beyond the short-term.

As the land climbs sharply into the Otlukbeli Mountains, between KPs 439 and 508, the diversity of landform increases with striking broadly rounded and deeply dissected hills, with grassy sub-alpine meadows and montane steppe, used in places for summer grazing. High elevation grasslands in the eastern part of the Otlukbeli Mountains and alpine vegetation in the western part are vulnerable to long-term damage because of their poor shallow soils, and harsh climatic conditions, which will delay reinstatement. High elevation grasslands may therefore prove difficult to reinstate and even with care, the visual impact can be expected to remain up to five years after construction has been completed. Further important mitigation measures to be applied will be narrowing the construction corridor to as narrow a width as possible, use moveable equipment mats to spread vehicle weight and avoid deep rutting, thereby reducing the impact of heavy machinery and implementation of fertiliser trials using NPK and micro-nutrients on reinstatement species. The possibility of undertaking construction during early spring when the ground is still snow-covered and frozen will also be investigated since this technique is used successfully in arctic tundra environments. At such times it may be possible to lift frozen turfs, which is impossible in the summer because of low root mass and friable soils, and replace them with little damage. Generally, impacts will be localised, although if repeated along this stretch they could be viewed as reaching a regional scale. They will extend beyond the short-term but can be regarded as being reversible in the longer term.

From KP 508, the pipeline descends to the flat valley of Ilgar Creek where it crosses electricity transmission lines and a major highway. The landscape is characterised by cropland with river banks covered by dense bushes and trees. Localised, short-term moderate to minor impacts are expected to occur on lower lying cropland where re-vegetation will be easier to achieve than on the higher elevation grasslands in the Otlukbeli Mountains.

Although the natural gas pipeline (NGP) Contractor will reinstate topsoil on the NGP corridor prior to construction of the BTC Pipeline, thin marl soils are unlikely to reinstate to a high standard and visual traces will remain. The NGP reinstatement strategy will provide indirect positive benefits, however, impacts will extend beyond the short-term where exposed marl retains its whitish colour and shows as a white line across the landscape between KPs 568 to 589 and KPs 610 to 674. This will be particularly evident from KPs 610 to 631 due to the surrounding high quality scenery, especially from viewpoints over the Acioz River. However, this impact will be minor to moderate between KPs 589 to 610 and may be reduced in more exposed rocky terrain where vegetation loss may not be so pronounced. As previously described in Section 15.2.1, mitigation measures to be applied in areas where marl occurs will include tailoring topsoil removal to the actual thickness present, implementation of fertiliser trials using NPK and micro-nutrients on reinstatement species with mulching using coir fibre or equivalent and a suitable replanting programme. Impacts will therefore be reversible and their overall duration will be reduced. Even if success in reinstatement is only patchy it will reduce a regional visual impact to more localised ones.

The route crosses the floodplain of the Zamanti River near KP 795 and passes along the western side of the Sariz River valley before crossing the Sariz River at c. KP 879. The wet meadows and marshland either side of the Zamanti River and along the Sariz river valley are extremely sensitive and will show a long-term/permanent scar unless care is taken with heavy machinery during the construction period. The localised, moderate residual impacts on the wet meadows/marshland in the Zamanti and Sariz valleys are reversible and will therefore last no more than 1-2 years after the above mitigation measures are undertaken.

Moderate residual impacts of a similar nature to that described for the Zamanti and Sariz River Valleys are predicted between KPs 924 and 961. The landscape sensitivity of the valley is moderate to high. Although construction will not take place in the wet meadows along the river, access from the main highway across the river valley has the potential to cause visual impact and will be restricted to the absolute minimum of crossing points, with vehicle movements carefully controlled. Loss of juniper scrub and residual impacts arising from thin stony soils will limit the success of reinstatement giving rise to long-term/permanent visual effects. However, the impact on the wet meadows/marshland in the valley will therefore last no more than 1-2 years where the above mitigation measures are applied.

South of KP 832, the pipeline follows a ridgeline for approximately 6km through sparse forests of juniper and oak and montane steppe habitat. The residual impacts along this section of the route have been reduced to moderate-to-minor, following the re-routing of the pipeline to avoid the high landscape quality of the Kirkgecit Valley. Although the precise residual impacts of the route change cannot be determined at this stage, it is anticipated that these will be reversible and localised and may be further reduced following detailed survey of the route change. Prior to the onset of the construction phase, a detailed survey will be undertaken as the basis for developing site-specific mitigation measures.

Pump Stations

Localised, moderate long-term landscape and visual impacts are expected on recreational users in the vicinity of Pump Station 1 (PT1), which will occupy an area of 13.4ha.

PT1 has been located within the rural environment to minimise its impact on residential properties and wooded areas. Therefore, the main visual receptors to visual impact at PT1 will be those travelling between Ardahan and Posof and to visitors using the Posof Wildlife Protection Area for recreational purposes. In addition, because of the mountainous terrain, views of the PT1 will be relatively limited in extent and receptor points will be largely remote and little visited. The removal of any existing mature trees, particularly those that may

provide natural screening, will be minimised. Planting and landscaping around the site perimeter will reverse impacts to some extent as growth becomes established.

Residential properties, for example at Baskoy, with medium distance views of PT3, (KP 444.2), are expected to experience localised, moderate long-term visual impacts. The PT3 site is predicted to be visible for up to c. 4km to the north and south. The landscape value within the vicinity of the PT3 site is considered to be low and landscape impacts will be minimum.

Similar impacts will be experienced at PT4 (KP 738). There will be a relatively large area of visual influence due to the generally flat terrain in which the site is located. The settlement of Alaca, (2km to the east of PT4), will have the clearest views of the station and residential properties on the eastern edge of the settlement will be most affected by moderate long-term visual impacts. The settlement itself will screen views from the west side of the settlement.

The recently relocated Pressure Reduction Station (IPT1) will be located near to the village of Geben and will require a landtake of 6.66ha (comprising 3.17ha of permanent landtake and 3.49ha of temporary landtake). Landscape surveys will be undertaken and landscape plans will be developed that identify detailed measures to reduce both landscape and visual impact at the Pressure Reduction Station. These will be developed by a landscape specialist, based on the building and site layout, alignment and location within the context of immediate and more distant landscape features. Similar mitigation measures as those recommended for the pump stations will be applied including landscape planting by specialists within the site boundary using native trees and bushes; opportunities to retain the existing landform; new landform screening where possible and neutral colours on structural surfaces to blend in with surrounding terrain and vegetation. As with the pump stations, it is anticipated that some visual impacts will be reversible and that over the longer term impacts may be reduced from moderate to minor.

Consultation with local communities during public disclosure will help to further identify mitigation measures that can be adopted to minimise impacts to the communities identified in Section 7.

Block Valves Stations (BVSs)

Nine settlements are located within 500m of the block valve sites, with predicted short-to-medium impacts expected to be moderate. During reinstatement of the pipeline re-vegetation of the perimeters of block valve stations will be utilised to screen them from nearby receptors.

15.2.2.3 Groundwater

The pipeline route passes over three major groundwater resources, which will experience localised, short-term moderate residual impacts during pipeline construction:

- Pasinler Plain (unconfined aquifer) crossed by the route between KPs 259 – 278. Water samples taken from wells close to the route indicate that groundwater quality is Class I;

- Goksun Plain (unconfined aquifer) crossed by the route between KPs 909 and 924. Water samples were taken from wells close to the route over this aquifer indicate that groundwater quality is class I, with the exception of groundwater taken from one well, which was class II;

- Springs on the Erzincan Plateau crossed by the route between KPs 488 to 519. Water quality classification unknown.

Groundwater quality is therefore high in both Pasinler Plain and Goksun Plain unconfined aquifers and suitable for drinking water supply (post disinfection) and water supply for food industries. Springs on the Erzincan Plateau are known to be used for drinking water by settlements in the vicinity of the route. Mitigation measures that will be applied to avoid reducing groundwater quality and conflicting with other users will include no groundwater abstraction within 50m of springs or wells and no permanent facilities or temporary sites (eg fuel storage, pipe laydown or construction camps), to be located within 50m of springs or wells. Groundwater quality will be monitored during construction in these sections. In addition, strict adherence to the mitigation measures contained in the Environmental Management and Monitoring Plan (EMMP) and Pollution Prevention Plan (PPP) will be required. However, where mitigation measures described are applied, impacts are predicted to be moderate, short-term and localised.

Following treatment, there will be a single wastewater disposal location for all treated effluents (see Section 7). The preferred option is for disposal via soakaway (further site investigations at each pumping station site is required to determine if the geological conditions are appropriate). The impacts due to discharge by soakaway will be moderate-to-minor based on the criteria outlined in Section 3. Similarly, the impacts associated with a discharge to surface water will be moderate-to-minor based on the project discharge standard requirements.

The assessment of residual impacts to groundwater has taken into account the considerable uncertainty that exists with regard to the quality and sensitivity of groundwater resources and the means by which wastewater will be discharged. The precautionary approach adopted by the EIA team has required that the 'worst case scenario' be considered at all times. Accordingly, the predicted moderate-to-minor residual impacts should be viewed as representing a worst-case outcome.

The appropriate discharge licenses and permits will be obtained from the relevant Turkish authorities and all aqueous discharges from the AGIs will be designed to ensure the appropriate Turkish and World Bank discharge limits (see Section 3) and any additional permitting conditions are met regardless of which method of disposal is selected.

15.2.2.4 Ecology

Protected Areas

Localised, short-to-medium-term, moderate impacts are expected where the pipeline passes through the Posof Wildlife Protection Area. The residual impact in this area has been reduced from major through the re-routing of the pipeline to avoid dense forest and to reduce significant habitat fragmentation and through the programming of works to avoid sensitive periods (see Attachment 1 to Appendix C1). In addition, the working width in this ecological sensitive area will be narrowed to 8m in patchy areas of dense forest for a total of 300m and the construction works will be limited to a 21-day period from when the area is entered to the completion of reinstatement works. Further mitigation measures to reduce this impact will be identified through site-specific vegetation and faunal surveys, to be undertaken by a qualified ecologist, (appointed as described in the EMMP), prior to construction. In the longer-term (5-10 years from the completion of construction works) impacts may be reversible, such that the long term residual impact is Minor.

Ecologically Sensitive Areas (ESAs)

In ESAs 1 to 5, 8 to 13, 15 to 22 and 25 to 49, moderate, localised residual impacts are anticipated as a result of disturbance to internationally important flora identified during ecological surveys. The degree to which disturbed areas will be recolonised by important flora is uncertain; as a consequence the localised, moderate impacts may be medium to long-term in extent. To reduce the overall impact, the Construction Contractor will ensure that construction planning achieves a 21-day period from the time when an ESA is entered to the completion of reinstatement works (see RP, Appendix C2).

Further site-specific mitigation measures to minimise impacts within ESAs will be identified through pre-construction surveys, which will be undertaken in these areas by a qualified ecologist to provide an accurate map of the location of endangered or threatened plant and animal species. In addition, as the globally threatened plant species, *Scrophularia versicolor*, was recorded within both ESAs 3 and 4 and *Onosma liparioides* within both ESAs 19 and 20, diligence will be exercised in searching between these areas. Diligence will also be exercised in searching inside the construction corridor in ESA 34, 35, 38 to 46 for those species known to occur just outside of the ESA.

The feasibility of translocating species to appropriate habitat outside of the RoW or construction area will be assessed prior to construction. Where translocation is not feasible, mitigation measures will include narrowing the RoW and removal, nurturing and replacement of turfs containing endangered or threatened plant species within the RoW or at temporary construction areas.

However, as residual impacts cannot be determined precisely for the re-routed section of pipeline that is outside the 500m Corridor at ESAs 12, 24 and 38, field investigations will be carried out prior to construction to determine whether the length of re-route is a continuation of the ESA. Specific mitigation will be developed following field investigations.

ESA 36 (the Zamanti River floodplain) will be crossed with the utmost sensitivity. Additional mitigation measures will be applied to reduce the impact in this area and will include commencing the crossing in August to minimise disturbance to sensitive periods for breeding birds and returning autumn migrants (between April to July). The RoW will also be narrowed to the minimum possible (<10m) and the pipeline strung outside of the marshy habitat and pushed or pulled through the trench. Heavy machinery working on the marsh will be supported on moveable equipment mats. Vegetation containing valuable species will be lifted as turfs, marked, nurtured and kept wet while being stored, and replaced in sequence.

Medium-term impacts to internationally important flora and supporting habitats are predicted for ESA 24. Although, mitigation measures will ensure losses are minimised, disturbance effects may still be detectable after several years due to the fragility of the alpine zone ecosystem along this length of the route. Repetition of moderate impacts in this section of the route will be avoided, as these would constitute a major impact.

Moderate impacts on globally threatened plants are predicted to occur at PT3, which is located on the edge of ESA 19, and may potentially contain a lower density of some globally threatened species. Extra care will be taken at this site to ensure the area affected by construction activities is minimised where practicable and the location of laydown and staging areas will be determined in consultation with expert ecologists to avoid sensitive species as far as practicable. Additional vegetation and faunal (including birds) surveys will be undertaken at this site prior to construction to confirm the presence and abundance of these species at this site. Site specific mitigation measures will be developed based on the findings of these surveys. Any particularly sensitive areas near the PT3 site, as determined by

botanical specialists, will be fenced or clearly demarcated and will be off-limits to all construction personnel.

Impacts from the block valve sites located within Environmentally Sensitive Areas (ESAs) (ie BVS 6, 14, 49 and 50) are predicted to be moderate due to the small area of sensitive habitat affected and the identified mitigation measures. These measures will be adopted to minimise the loss of habitat and sensitive species during construction at these sites (see Section 6).

Important species

The construction activities associated with the crossing of rivers have the potential to disturb breeding fish, birds, mammals and reptiles and damage the aquatic plants that provide breeding and foraging sites. Impacts may be Moderate to Major, where construction is undertaken during the sensitive seasons for these species. Seasonal sensitivities associated with the river crossings will inform the preparation of construction programmes for each of the spreads (within other construction schedule constraints) in line with the seasonal sensitivities table presented in Attachment 1 to the EMMP.

The further mitigation of ecological impacts through the management of construction activities within ecologically sensitive sections of the route is grounded upon two complementary principles:

- Firstly, that existing data on the species and habitats potentially impacted by the BTC Project will be improved through extensive pre-construction surveys. The information derived from the surveys will reduce the levels of uncertainty that have necessitated a largely precautionary approach to the assessment of impacts, whilst providing the basis for robust site and species specific mitigation strategies to be developed and implemented.

- Secondly, that construction works at a significant number of locations along the pipeline route will be programmed according to the seasonal sensitivity of potentially impacted species. Whilst programming flexibility at some locations is contingent upon the results of pre-construction surveys, the principle of avoiding key periods of particular ecological vulnerability will reduce direct impacts to key species as well s ensuring that construction management in key habitats is focused on ecologically derived objectives. The prioritisation of ecological issues will benefit not only key species but also a range of associated species and habitats.

The basis of these principles, and the mechanisms through which further mitigation measures will be implemented, are incorporated within the EMMP, in particular the seasonal sensitivity tables included as Attachment 1 of the EMMP, and the management of revegetation and recolonisation in areas of important flora is further discussed in the RP (Appendix C2).

15.2.2.5 Noise

A total of four settlements and one industrial area will experience short-term, localised moderate residual impacts during construction that will be reduced to as low as reasonably practical by use of various noise mitigation measures, including:

- the industrial area in Erzurum Province is located directly adjacent to the pipeline route between KPs 279 to 282. Commercial properties such as offices may be sensitive to noise during pipeline construction, although these properties will be less sensitive to noise than residential dwellings and schools. Noise impacts are expected to occur during each phase of construction;

- the settlement of Catalbayir (in Erzurum Province) is located approximately 96m from the centreline of the pipeline and will experience short-term noise impacts during soil stripping, welding/lowering and backfilling activities;

- Gozeler in Erzurum Province is located approximately 250m from the pipeline centreline near KP 408 and adjacent to a National highway crossing. Noise impacts are therefore expected to occur at Gozeler during sheet piling associated with the highway crossing;

- Cilhoroz (in Erzurum Province) is located approximately 141m from the centreline of the pipeline and near to a crossing of the NGP. Short-term noise impacts are expected to occur at during soil stripping, excavation works, welding/lowering and sheet piling works associated with the NGP crossing;

- Kirkgecit in Kayseri Province is located approximately 65 m from the centreline of the pipeline. Short-term noise impacts are expected to occur during soil stripping, welding and lowering, backfilling, bending and trenching activities. Blasting works may also be required in this area and are also expected to give rise to noise and vibration impacts at Kirkgecit.

The following mitigation measures will be applied in all five industrial/residential areas:

- use of silenced/low noise construction plant and machinery;
- provision of routine checks and maintenance to ensure that plant is operating efficiently and not giving rise to high noise levels;
- all hours of work will be agreed with the relevant authorities prior to the commencement of works;
- plant and machinery will be sited away from inhabited buildings;
- existing screening, including that arising from the stockpiling of materials and spoil will be utilised wherever possible;
- mobile noise barriers will be used where possible to screen noise impacts to the Industrial Area and Gozeler.

Soil stripping and welding/lowering activities will be short-term activities occurring for one to two days during each phase of construction. However, works at the NGP and the highway crossing near Gozeler will take three to four weeks to complete. Although noise and vibration from potential blasting near Kirkgecit may give rise to annoyance to residents, it is unlikely to cause structural damage to buildings. The Contractor will carry out detailed noise and vibration predictions once the specific blasting methods have been developed. The proposed method of working and mitigation measures will be agreed with the relevant authorities in advance of works taking place. Residents will also be notified in advance of works involving blasting. In addition, the construction Contractor will develop site-specific noise mitigation measures for the duration of these activities, monitor their effectiveness and demonstrate that impacts will be minimised to the maximum extent possible as part of the PPP.

15.2.2.6 Cultural heritage

Nine archaeological sites are predicted to experience moderate to minor impacts during pipeline construction:

- Tasmasor Area (1st-3rd Degree Site[1]) – southern part of site crossed by the route;
- Cayirca-Beypinari (2nd Degree Site[1]);
- Beypinari-Kahramanlar (2nd Degree Site[1]);
- Koyunkaya Alaouite cemetery (1st Degree Site[1]);
- Cetelik Tumuli comprises two adjacent tumuli (no Ministry of Culture (MoC) classification);
- Archaeologically important site south west of Kilickoy settlement (no MoC classification);
- Meryemcil Castle (1st Degree Site - registered by the MoC) – route passes close to the foot of the hill at this site. The majority of the castle ruins are still standing and could potentially experience structural damage and vibration impacts during pipeline construction;
- Islamoglu (Kirteke) Mound is a settlement mound located on the edge of the 100m Corridor. Part of this site has been registered by the MoC as a 1st Degree Site, with the remaining registered as a 3rd Degree Site;
- Gokdere (3rd Degree Site[1]).

A further nine sites have been identified for intensive preconstruction archaeological surveys. These are located in the following areas: Tetikom; Hoyugu; Tasinonu; Algiz; Yerlesimi; Yesilkaya 2; Minnetpinari; Tasoluk - Kovici and Maltepe - Guney.

However, the residual impact cannot be determined precisely for these sites at this stage, since the extent of the sites is not fully determined. Archaeological investigations will therefore be undertaken prior to construction, as part of the Cultural Heritage Management Plan (see Appendix C7), to establish the full extent of each of the sites. This will determine the need for further archaeological action. Site-specific mitigation measures will be developed following site investigations. The Koyunkaya Alaouite cemetery is expected to be avoided by the route, as one objective of these investigations is to identify a route away from the site, to the north of the current BTC Pipeline alignment and the NGP.

In addition, investigations will determine whether Islamoglu Mound extends into the Working Corridor and may experience impacts during pipeline construction.

As site investigations are expected to provide for appropriate archaeological actions to be undertaken in order to minimise impacts to the site, the ultimate scale of impact is likely to be minor. Furthermore, the Tasmasor Area has already been disturbed during construction of the gas pipeline and the NGP reinstatement strategy may provide the potential for a positive impact and improve the setting of the site.

Throughout pipeline construction in the vicinity of these sites, construction activities will be carried out under the supervision of an archaeologist authorised by BOTAŞ. If blasting is required, then it will be conducted in such a way that it does not pose a threat to the integrity of buildings still standing on the Meryemcil Castle site. To avoid vibration impacts, percussive piling will be not allowed within 100m of the site. The construction Contractor will adhere to the requirements of the Cultural Heritage Management Plan during construction through these sites.

[1] These sites have not yet been registered by the Ministry of Culture and are provisionally assigned this classification

The residual impacts outlined above relate to known sites of archaeological importance. However, the assessment of potential impacts to buried archaeological deposits has also considered the implications of currently unrecorded sites and features that might be revealed during the construction phase. While it is likely that additional archaeological resources will be encountered, the watching brief and archaeological response provisions, contained within the CHMP, provide appropriate mechanisms for ensuring that mitigation measures are effectively implemented. The ongoing management of the uncertainty associated with unrecorded archaeological deposits will be the responsibility of the Archaeological Management Consultancy and the BOTAŞ Project Archaeological Inspector, working through the archaeological specialist appointed by the Contractor.

15.2.2.7 Residual impacts associated with the Contractors' intended approach

A number of issues have been identified by the EIA process as requiring specific resolution during construction planning. The contracting philosophy for the BTC Project is grounded upon standard commercial contracting principles that invites the Contractor to propose specific solutions to a range of issues and challenges, including precise method and timing of works, materials procurement, workforce mobilisation etc. It should be stressed, however, that the permissible tendering flexibility inherent in this philosophy is contingent upon the Contractor fully complying with the requirements of the Contractual Documentation, including the EIA and its associated Environmental and Social Management Plans.

As a consequence, detailed proposals with regard to a number of issues (in particular waste management, traffic and transportation management and aggregate winning) will only emerge following the selection of the preferred tenderer. In parallel to the tender assessment process, the BTC Project is collating provisional information on potential aggregate sources, waste disposal facilities and construction haulage routes, to enable the Project to be able to assess the acceptability of received proposals.

Owing to this element of current uncertainty, the EIA has stressed the importance of the Management Plans as the key vehicles for delivering appropriate and effective measures for managing, controlling and mitigating environmental and social impacts associated with these activities and issues. In this regard, on the basis that the Management Plans will be rigorously implemented and enforced, a conservative approach has been adopted in identifying the level of significance of identified impacts in this EIA.

Whilst this planned uncertainty has not affected the robustness and integrity of the EIA process, the *potential* for residual impacts remains pending the resolution of these issues. The implementation and maintenance of the provisions of the Management Plans will be a key contract management priority and will be informed by internal and external performance monitoring and audit.

15.2.3 Significant residual social impacts: most important

This section describes the significant residual social impacts that, based on professional judgement and feedback from consultation, have been identified as being most important: These comprise:

- impact on livelihoods close to Pump Station 1 (PT1);
- unplanned disruption to infrastructure and services provision;
- tensions due to the limited number of employment opportunities.

The numbers of people likely to be affected by these impacts are predicted to be small, and, with the exception of the impact of PT1, the duration of the impact will be short-term (no greater than the duration of construction activity). However, due to the poverty in which many individuals live and the consequent implications of any reduction in their livelihoods or quality of life, any reduction in household livelihoods is considered to be significant.

15.2.3.1 Impact of Pump Station 1 on local livelihoods

The proposed PT1 is located near the rural settlement of Sogutlukaya in Ardahan province, resulting in the permanent acquisition of 13.4ha of land and an additional 12ha of land (over a 32 month period) for the temporary construction of a campsite. One hectare of land will also be permanently acquired for a gendarme station that will be located nearby PT1, on a site selected in consultation with local residents. These areas of land are currently used for communal grazing purposes.

Due to the concern raised by the residents over the last six month, the potential impact in Sogutlukaya will be considered significant until figures on the extent (and quality) or alternative grazing land are known and the compensation package is available for evaluation (refer to Section 7 for a more detailed discussion of this impact).

15.2.3.2 Unplanned disruptions to infrastructure and services provision

The mitigation measures identified for infrastructure and services will, if implemented correctly, prevent any planned significant negative impacts both during and post construction. However, in a project of this size it is likely that there will be instances when infrastructure or services (eg roads, irrigation channels, water supply, electricity supply) are disrupted without notice or prior planning. Such disruptions could affect people living over large areas and, although temporary, there is a possibility that an unplanned disruption could hinder the income generation and subsistence activities of those affected. Any impacts incurred are unlikely to last beyond the short term.

In accordance with the requirements of the Construction Impacts Management Plan and Community Liaison Management Plan, the Contractor CLO will notify authorities of affected settlements regarding occurrence of unplanned disruptions, as well as expected duration of disruption and measures to be taken to rectify incident. A Complaints Procedures will also be operated to allow for reporting and resolution of any grievances. Where appropriate, compensation will be provided for any losses incurred. This will assist in preventing any serious impacts on the ability of those affected to maintain their livelihoods and to prevent them becoming a source of tension with the Project.

15.2.3.3 Management of employment expectations

Unemployment levels in rural Turkey are high. The number of people who will gain employment on construction of the pipeline and associated AGIs (approximately 5,000), although substantial, is low when compared to the population of the directly affected settlements and surrounding area. Residents in directly affected settlements that are unsuccessful in their job applications to work on the pipeline construction, or within the camps, may become frustrated when they do not gain employment. It is also likely that residents of settlements just outside the directly affected project area will be frustrated that they will not get priority access to jobs despite their relative proximity to the pipeline route. District centres in the area may also anticipate greater employment opportunities than actually exist. These unmet expectations could create resentment towards those who succeed in getting jobs, and also towards the Project. Although unmet expectations could be widespread, ranging

from local to regional and possibly national, tensions developing around this issue are likely to be localised.

The disclosure process of the EIA and a wider communication strategy regarding employment opportunities will assist in managing expectations regarding employment opportunities, thereby reducing this impact. The community liaison team will also have a key role to play in managing any tensions, should they arise. These measures are described in more detail in the Employment and Training Management Plan and the Community Liaison Management Plan (Appendix C8).

15.2.4 Other significant residual social impacts

This section describes the significant residual social impacts, which, although important, have a higher degree of assurance regarding the effectiveness of the proposed mitigation measures. These relate to health and safety of local residents and livestock, social and cultural disturbance to local residents and grievances over land compensation.

Health risks

There is a minor residual risk that the existence of construction camps and the interaction of the workforce with local residents might either introduce new diseases to the country or the region, or might increase the rate of transfer of disease. The likelihood and severity of this will depend upon the health of the workforce and the level of interaction with local settlements. To minimise health risks, all personnel will undergo health screening. No-one suffering from a transmittable disease will be allowed to work on the project. Thereafter, all employees will be immunised, if required, and will be involved in on-going health programmes, including regular check-ups (see the Disease Awareness and Prevention Strategy in Appendix C8). Based on these mitigation measures, any incidents of disease are likely to be highly localised and will continue for the short or long tem, depending on the nature of the illness.

The likelihood of increasing levels of sexually transmitted diseases is considered to be low due to the conservative nature of rural settlements and government regulation of licensed brothels, including regular health checks for all sex-workers. However, the Project will act to further minimise the risk through health awareness raising with the workforce and local settlements (in the vicinity of construction camps), and making condoms freely available from the camp doctors (See Disease Awareness and Prevention Strategy in the Community Safety Management Plan, Appendix C8).

The likelihood of the Project exacerbating health problems in the area is therefore considered to be low.

Safety of local residents and BTC workers

Construction working areas and higher traffic loads will pose safety hazards to local residents, particularly small children and BTC workers. While considerable mitigation measures have been put in place to address such impacts (eg safety briefings, traffic control measures, driver training, fencing), there will be a residual, although small, likelihood that accidents could occur. Continued attention to mitigation measures will be critical to prevent any injuries from occurring. These are detailed in the Community Safety Management Plan in Appendix C8. As part of induction training, all workers, including contractors and sub-contractors, will be trained in Project Health, Safety and Environment (HSE) policies and procedures.

Social and cultural disturbance

It is critical that the social and cultural values of all settlements neighbouring the pipeline route and construction camps be respected. Extensive mitigation measures are in place to ensure that this occurs. As such there is only a low likelihood of any residual impacts occurring. Any incidences that arise from a breach in rules and procedures will be rapidly resolved. Any associated tensions are thus only expected to persist for the short term, although the potential for long-term damage to relations is however recognised.

A complaints procedure will be operated by the community relations team to allow for the reporting of grievances and their rapid resolution by the Project. On-going community liaison with project-affected settlements will also be undertaken, as well the enforcement of the worker Code of Conduct. Should additional construction camps be required, these are to be located at least 5km from settlements identified as having resistance to construction camps, wherever possible. These measures are detailed in the Employment and Training Management Plan and the Community Liaison Management Plan in Appendix C8.

Grievances over land compensation

The pipeline will require the purchase and use of land that is used predominantly for agriculture and grazing, or in some instances, forestry lands. Where this land is communal, or where there is uncertainty regarding land titles, there is the potential for complications to occur in the expropriation process. The land acquisition process will address such issues in detail through a series of mitigation and monitoring measures. Therefore, the potential residual impacts are reduced. An overview of the land acquisition process (OLAP) is provided in Appendix C9.

However, experience from previous expropriation in Turkey suggests that there may be disputes and disaffection between the Project and some landowners and users on the pipeline route. These could result from perceived or actual instances of disagreement with regard to the compensation process. This could cause resentment and possibly tension between the Project and affected landowners. Such tensions are only expected to last until an acceptable settlement is reached between the parties concerned.

The nature and scale of these negative residual impacts will depend on the quality of implementation of the land acquisition and compensation process, community relations, and the Complaints Procedures.

15.2.5 Residual social benefits

The negative residual impacts identified in Section 15.3 need to be balanced alongside the positive impacts that will be brought by the Project. The positive impacts of a project such as BTC are generally concentrated at the national level through the economic and strategic benefits that the project brings. The EIA process and associated work carried out by the Project have focused on identifying the areas where the Project can bring more local benefits. The main areas of benefit that are predicted stem from health awareness training, clarification of land tenure, the employment and resourcing strategies and the benefits resulting from the EIA consultation process. The Project will also look for formal and informal ways of linking project infrastructure needs into existing infrastructure and service plans, thus resulting in long-term benefits for local residents.

The benefits associated with the Project occur on the local, regional and national level and, with the exception of employment during construction, will endure both for the long-term and

permanently. Temporary employment will, however, result in indirect benefits, which are long-term and permanent in nature.

Direct and indirect employment creation

The greatest positive socio-economic contribution that the BTC Pipeline Project can bring to local settlements is direct employment and the stimulus that local purchasing can bring to the local economy. Employees will directly benefit from secure, although short-term, income and will gain skills and experience that may assist them in seeking other employment. Local settlements will further benefit from the money spent by the work force.

In response to the high priority placed on this by the local people and their representatives, the Project has committed, wherever possible, to preferential use of local workers and purchase of local goods and services. The key issue in determining the level to which this boosts local economies are the total number and duration of employment opportunities, the source of the workforce (local, Turkish, international) and the degree of local procurement undertaken. Whilst this will be determined with the Contractor during contract negotiations, the Project expects that:

- the vast majority (target of 90%) of the unskilled workforce will come from settlements directly affected by pipeline construction;
- a high proportion of the semi-skilled workforce (target of 80%) will come from the districts and provinces through which the pipeline passes;
- a high proportion (target of 80%) of the skilled workforce will be Turkish nationals.

Approximately 5,000 people will be directly employed by the Project, approximately half of whom will be unskilled and therefore from project affected settlements. Half of these unskilled workers will be employed on the pipeline spread for approximately two month's duration each, and the others will be employed at the construction camps and pump stations for up to 2.5 years. By ensuring that recruitment takes place at a number of locations along the route, more people will have an opportunity for employment, thereby spreading economic benefits more widely.

For more details, see the Employment and Training Management Plan in Appendix C8.

Enhanced recruitment and contracting practices

The Project has committed to developing, publicising and implementing strategies for recruitment and purchasing. These strategies will emphasise transparency and integrity through: the timely and widespread provision of information on employment and supply opportunities and procedures; establishing and reporting on targets; and putting in mechanisms for third party oversight.

It is considered that this will set an important precedent in terms of the way in which recruitment, employment, contracting and purchasing is managed. This could potentially have a significant positive residual impact on future employment and sourcing practices in the regions in which the Project occurs, and possibly more widely.

For more details, see the Procurement and Supply Chain Management Plan in Appendix C8.

Enhanced local experience and employability

There will be benefits in terms of the additional experience and skills gained by construction and operational workers, resulting in an enhancement of future employment prospects. This

will apply to all workers, being of greatest significance for those participating in skills development programmes and for those skilled workers who will be employed for longer periods. The potential to benefit from these enhanced skills depends to some extent on the ability of workers to find other construction jobs where their experience is valued. Professional (office-based) workers are likely to have enhanced employment prospects, as they will gain and/or enhance skills suitable for positions in other industries.

Skills developed by local businesses through contracting and procurement processes will enhance their ability to respond to other international tenders. These will include overall business management skills such as quality assurance and project management. The scale and distribution of this positive impact will depend on the number of contracts given to local contractors.

For more details, see the Employment and Training Management Plan and the Procurement and Supply Chain Management Plan in Appendix C8.

Land tenure clarification

A minor positive residual impact will be the clarification of land tenure status of those lands without legal title deeds that are crossed by the pipeline (within the 28m corridor). In order to award expropriation payments, such legal clarification is required. This includes the ownership rights of heirs who have not registered their inherited rights to land, and customary ownership rights.

Clarifying land tenure status allows owners to use their land as collateral against which they can loan money to invest in improving their future livelihood. It also helps to prevent future conflicts arising over land rights.

Increased capacity to interact with development projects

The consultative process associated with this Environmental Impact Assessment has engaged stakeholders from the international to the local level, including residents from potentially affected settlements, local authorities and NGOs. It is expected that this consultative process, and its extension into the implementation phase of the project, will deliver benefits to stakeholders in terms of building understanding of the project planning process and capacity to interact with development projects.

Improvements to infrastructure and service provision

Benefits for local settlements will be realised should the Project and other parties be successful in linking Project infrastructure needs into existing infrastructure and service plans (eg road upgrades, sewerage treatment, waste management and water supply), thus resulting in long-term benefits for local residents. These opportunities are particularly strong in relation to settlements close to pump stations that have very limited infrastructure. Efforts by the Project to link infrastructure in this way will serve to build relationships with residents and prevent any resentment from the settlements towards the Project.

Improved health awareness

Mitigation measures will result in the training of all workers employed on the BTC Project (international, national and local) in health and safety (including hygiene and STD awareness). In addition, the Project is committed to working with district and provincial health authorities in awareness raising on health issues for settlements close to construction camps and pump stations (via posters, leaflets, through health clinics, community meetings

and availability of condoms from the camp doctor, without charge). These efforts will deliver significant benefits in local settlements in terms of raising awareness of important health issues.

For more details, see the Community Safety Management Plan (Disease Awareness and Prevention Strategy) in Appendix C8.

15.3 RESIDUAL IMPACTS AT THE MARINE TERMINAL

15.3.1 Introduction

This section describes the residual environmental and social impacts of the BTC Marine Terminal. As described previously, significant environmental residual impacts are those that have been evaluated as Moderate or Major, according to the criteria established in Section 3. With regards to the significant social residual impacts, these are divided into those that are viewed as most important and those that are still significant but viewed as readily amenable to management. With regards to both environmental and social impacts, the evaluation of significant impacts stems largely from uncertainty factors and a cautious assessment. The following descriptions have therefore also set out how uncertainty will be addressed and managed.

15.3.2 Residual environmental impacts of Major significance

Major, long-term, localised visual impacts are predicted to the residents of Sahil Sitesi. Although a series of landscaping mitigation measures are proposed that will soften the overall impact, such measures will not obscure the major structures (ie the tank farm and jetty) and the visual presence of large tankers at the jetty.

The assessment was based on a fairly conservative application of the significance criteria, which has not yet been tested in consultation with the affected community. Before and after photomontages have been prepared for the disclosure phase (and are shown in Section 12) so that views of the affected communities on impacts to visual amenity can be gauged more clearly and further mitigation measures can also be explored.

15.3.3 Residual environmental impacts of Moderate significance

15.3.3.1 Visual impacts

Moderate, long-term, localised visual impacts are predicted to the residents of Golovasi, Hamzali, Kurtgulagi, Incirli and Karatepe. In addition, moderate impacts are also predicted for the recreational users of the BOTAŞ beach.

The landscaping mitigation measures, however, will not be able to obscure the major structures but will reduce the visual impact to as low as reasonably practical. From some views, impacts may be reversible in the longer term as planting takes effect. As described in Section 15.3.1, the assessment criteria used are precautionary and conservative. Consultation with local communities during public disclosure will help to identify further mitigation measures which can be adopted to minimise impact to the communities identified.

15.3.3.2 Impacts to terrestrial ecology

Ecological impacts from the construction of loading lines

Although ecological surveys of the tank farm site have been carried out, ecological surveys of the loading lines have not been undertaken to date. Such surveys are proposed prior to construction in order to identify any rare or noteworthy species. As the presence of such species is unknown at present, the construction of the loading lines has the potential to cause minor to moderate impacts to flora and fauna at the site. If such species are discovered, however, relevant mitigation measures will be put into place in order to minimise impacts to sensitive species, therefore the overall impacts is likely to be minor.

Impacts to reptiles

A number of nationally and internationally important species of reptile were identified at the terminal site. As reptiles demonstrate varying degrees of mobility, there is the potential for short-term and localised, minor to moderate impacts to reptiles during construction of the tank farm and the loading lines. It is anticipated that any impacts to reptiles will only occur during construction and will not last during operation as any displaced animals will move to similar adjacent habitats.

15.3.3.3 Impacts to coastal processes

The presence of the proposed BTC jetty structure has the potential to cause minor to moderate impacts to coastal processes. Longshore drift in the vicinity of the proposed jetty occurs in a northerly direction as evidenced by the build up of sand on the southern side of headlands and other coastal structures in the area. The volumes of sediment movement are relatively small. The solid causeway structure is likely to trap some sediment, preventing northerly drift, potentially starving the BOTAŞ beach to the north of the proposed jetty which may result in a slight decrease in size.

Monitoring of seabed levels and shoreline morphology will be conducted to determine the extent of changes on coastal morphology caused by the structure. If changes are viewed to be significant, remedial action will be undertaken to replenish the existing BOTAŞ beach. Although impacts are currently predicted to be moderate at most, appropriate mitigation measures (adopted where necessary) are likely to reduce the overall impacts to minor.

15.3.4 Most important significant residual social impacts

This section describes the significant residual social impacts that, based on professional judgement and feedback from consultation, have been identified as being most important. These include impacts on livelihood due to decreased access to fishing grounds and possible tensions due to the limited number of employment opportunities.

15.3.4.1 Fishermen livelihoods

Based on findings currently available, the predominant residual impact associated with the BTC Marine Terminal concerns decreased access to the fishing grounds that are currently used by residents of Golovasi and Sahil Sitesi. Based on the findings of the recently completed studies this impact is understood to be local in geographical scope and will endure for the long-term (ie for the life of the Project). The mitigation measures will include compensatory measures and the prioritisation of local residents for employment (see Employment and Training Management Plan and the Procurement and Supply Chain Management Plan in Appendix C8). Increased opportunities for wage labour, as a result of the on-going industrialisation in the Gulf of Iskenderun and surrounding area, are also expected to help mitigate against the loss of access to fishing grounds. The compensation process will

include an internal and external monitoring programme to ensure that the compensation package is successful. Where appropriate, actions to address any feedback received will be taken.

However, it is expected that residual impacts will occur irrespective of such mitigation measures. This is largely the result of the following:

- unskilled jobs associated with the Project are limited and will not be allocated exclusively to fishermen. Therefore, not all impacted fishermen are likely to secure employment on the BTC Project;

- while the majority of the employment brought by the Project will be limited in duration to the construction period (up to 30 months), the restricted fishing areas will be out of bounds for the full life of the Project (40 years). As a result, compensation measures will need to address the long term loss of a source of livelihood;

- additional developments in the Iskenderun Gulf compound the residual impacts associated with the BTC Jetty, particularly those that require their own Security Exclusion Zones. This issue is addressed separately in Section 16 as a cumulative impact. Such increased industrialisation, will, however, offer additional opportunities for wage labour in the area.

Loss of fishing as a form of livelihood (as a result of both general industrialisation in the area and decreased access to fishing grounds due to the BTC Marine Terminal area) is also likely to impact on fishing as a 'way of life'. The potential residual impacts associated with this change include decreased cohesion of the family as a working unit and, in the event that households no longer have reason to work together (as they did on the fishing vessels), this could impact on the sense of community and support networks within the affected settlements. In spite of local employment strategies and other mitigation measures, this residual impact is considered an unavoidable impact of increased industrialisation, of which the BTC Project is a part.

15.3.4.2 Management of employment expectations

Unemployment levels in rural Turkey are high. The same applies to the settlements neighbouring the proposed marine terminal. During construction, approximately 400 workers will be employed and approximately 100 workers will be employed during operation. Although local residents will be prioritised for unskilled employment, and semi-skilled workers from districts within Adana province, these employment totals are very low compared to the population of the directly affected settlements.

Expectations of employment featured prominently during the consultation process and helps to explain why the concerns of directly affected settlements (eg decreased access to fishing grounds; increased traffic levels; potential land take for terminal facilities) did not undermine overall support for the marine terminal. Although the mitigation measures include proposals to manage community expectations regarding employment, local residents have expressed disappointment regarding limited employment opportunities at the existing terminal.

The concern therefore exists that inability to deliver on these expectations could damage relations between the Project and some local residents. This could be further compounded by possible tensions among some local residents regarding the high standards of living enjoyed by workers in the construction camp, as already experienced in relation to BOTAŞ residents (employees and their families) within the existing BOTAŞ Marine Terminal.

The disclosure process of the EIA and a wider communication strategy regarding employment opportunities will assist in managing expectations regarding employment opportunities, thereby reducing this impact. The community liaison team will also have a key role to play in managing any tensions, should they arise. These measures are described in more detail in the Employment and Training Management Plan and the Community Liaison Management Plan (Appendix C8).

15.3.5 Other significant residual social impacts

This section describes the significant residual social impacts, which, although important, have a higher degree of assurance regarding the effectiveness of the proposed mitigation measures.

These include:

- a minor risk of increases in communicable diseases, due to interaction of construction workers and local residents;
- a minor risk of accidents (involving humans and/or livestock) as a result of construction activities, both within the BOTAŞ property and along access roads;
- unplanned disruption to infrastructure and service provision;
- impacts of in-migration to the project area.

These residual impacts (with the exception of in-migration) are similar in nature to those described in the pipeline residual impact section. The following differences should, however, be noted.

- Regarding health risks, increased industrialisation and population mobility in the project area is expected to have increased the resistance of local residents to communicable diseases.
- Regarding risks of accidents, construction activities (excluding construction traffic) will be confined within secure, off-limit areas within the BOTAŞ property, thus reducing the risk of accidents to local residents and livestock.
- Regarding impacts on infrastructure, the absence of large-scale irrigation networks within the marine terminal project area reduces the extent of this impact compared to that of the pipeline. However, a potential overload on existing services and accidental or planned disruption to utilities during construction, remains a residual risk in a project of this scale.

With regards to in-migration, the absence of large-scale in-migration to settlements neighbouring the existing BOTAŞ Marine Terminal indicates that a sudden influx of job seekers to the Project area is unlikely to occur as a result of the BTC Project. What is likely, however, is a gradual influx of job seekers to the Iskenderun Gulf area as a result of on-going industrialisation. The project area may therefore experience in-migration as a result of this general influx to the wider project area.

The potential impacts of in-migration are directly related to the capacity of the existing services and resources to support an increased population, and the ability of the resident population to adapt to any changes to standards of living and sources of livelihood. An overview of conditions in the project area indicates that the existing services and resources are not sufficient to meet the needs of either the current or additional populations. These impacts

will vary in duration (short-term, long-term or permanent) depending on the length of time that job seekers remain in the project area and the amount of time taken to improve services and create employment opportunities in the project area.

By way of mitigation, the Project will actively seek to discourage in-migration in search of employment or other project benefits (eg provision of local goods). This will be done primarily through the publication and implementation of the employment and purchasing strategies. Specifically, the following will be announced: preference for local labour; no recruitment at the construction camps for work site (recruitment centres to be publicised) and no purchase of goods at camp locations or work sites. For more details on these measures, see the Employment and Training Management Plan and the Procurement and Supply Chain Management Plan in Appendix C8.

Turkish citizens are, however, free to move within their own country and any migration to the project area cannot thus be prevented. A residual risk of in-migration therefore remains, along with the associated risks of decreased standards of living and increased competition for sources of livelihood in the project area.

15.3.6 Residual social benefits

The negative residual social impacts of the Project need to be balanced alongside the positive impacts that will be accrued. The positive impacts of a project such as BTC are generally concentrated at the national level through the economic and strategic benefits that the Project brings.

Residual socio-economic benefits at the local level are predicted to be as follows:

- limited direct and indirect employment creation;
- enhanced recruitment and contracting processes;
- enhanced local procurement and supply;
- enhanced local experience and employability;
- increased capacity to interact with development projects;
- improvements to infrastructure and service provision;
- improved health awareness.

These impacts are in line with those identified for the pipeline as a whole and are explained and expanded upon in Section 15.3.4.

15.4 SUMMARY

Managing the residual environmental and social impacts will be the main focus of ongoing environmental and social management throughout the lifetime of the BTC Project. The Environmental and Social Management and Monitoring Plans establish the principles and set out the frameworks for achieving this. However, these will apply not only to the impacts summarised in this section but also to the many environmental impacts evaluated as Minor to ensure that these are also properly managed and that they do not become Moderate or Major impacts. Similarly, these management and monitoring plans also apply to other social impacts identified in Section 6 and 12.

Table 15.1 summarises the key areas of residual impact, together with proposed Project actions. Also included are current areas of uncertainty that, if properly managed, will result in Minor impacts, but still contain an element of uncertainty and require further action beyond this EIA to fully address them.

Table 15.1 Key Areas of Residual Impact and Proposed Project Actions

ISSUE	PROJECT ACTIONS
Soils in certain sections of pipeline route	• engage soils expert • pre-construction surveys • enhancement of certain reinstatement measures • focus for post-reinstatement monitoring and aftercare
Landscape in certain sections of pipeline route	• same actions as stated above for soils
Landscape at Marine Terminal	• disclosure consultation feedback to assess further mitigation opportunities
Water quality and abstraction	• pre-construction surveys to identify suitable soakaway sites • risk assessment studies for groundwater aquifers • long-term monitoring • drawdown pumping trials • longer term monitoring
Biological environment at ESAs and other important sites	• timing and duration of works • pre-construction surveys • species transplantation • post-reinstatement monitoring and aftercare
Construction noise at certain settlements	• pre-construction surveys to establish true work-site to residence separation distances • re-assess noise exposures • re-assess attenuation effectiveness of purpose-designed noise barriers • further action in consultation with affected residents • monitoring
Flare noise at Marine Terminal	• investigate noise abatement design options • commissioning phase noise monitoring
Archaeology	• pre-construction investigations in accordance with CHMP • construction phase watching brief in accordance with CHMP
Quarries and aggregates extraction	• Contractors to quantify requirements • Contractors to identify licensed sustainable sources • formal EIAs and approvals for new sources (and reinstatement plans) • monitoring
Solid waste management	• Contractors to quantify volumes to type • Contractors to identify disposal locations on basis of licensed facility suitable for waste type • Contractors to identify disposal locations on basis of capacity to accept project waste without conflict with other users
Impacts associated with PT1	• further assessment required to determine significance of impact. • possibility of securing additional grazing land for residents

ISSUE	PROJECT ACTIONS
	of Sogutlukaya to be explored. • compensation procedures to be carried out. • internal and external monitoring to be carried out.
Unplanned disruption to infrastructure and service provision	• in accordance with the requirements of the Construction Impacts Management Plan and Community Liaison Management Plan, BOTAŞ CLO to notify authorities of affected settlements regarding occurrence of unplanned disruptions, as well as expected duration of disruption and measures to be taken to rectify incident. • operation of Complaints Procedures to allow for reporting and resolution of any grievances. • where appropriate, compensation for losses incurred will be provided.
Management of employment expectations	• distribution of the employment strategy (including details on extent and duration of employment) to all project affected settlements, at least one month prior to the date of recruitment. • the employment strategy to be publicised to sub-governors of districts along the pipeline route and in Adana and Yumurtalik districts. All governors in Turkey will also be informed.
Health risks	• develop and implement a Disease Awareness and Prevention Strategy in liaison with government health authorities and other expert health organisations in Turkey.
Safety of local residents and BTC workers	• on-going attention to the mitigation measures detailed in the Community Safety Management Plan and the BP HSE policies and procedures. This includes community liaison meetings (including women and children's meeting), securing the worksite and Project HSE training for all workers**.**
Social and cultural disturbance	• enforcement of worker Code of Conduct. • operation of Complaints Procedures to allow for reporting and resolution of any grievances. • on-going community liaison with project affected settlements. • if additional construction camps are proposed, these are to be located at least 5km from settlements identified as having resistance to construction camps, wherever possible. • all grievances to be addressed and resolved according to the Project procedures.
Grievances over land compensation	• completion of additional studies currently underway to clarify impact of BTC jetty on local fishing activities • if considered appropriate, compensation for decreased access to marine resources to be provided. • internal and external monitoring to be carried out.
Fishermen livelihoods	• completion of additional studies currently underway to clarify impact of BTC jetty on local fishing activities. • if considered appropriate, compensation for decreased access to marine resources to be provided. • Internal and external monitoring to be carried out.
In-migration	• distribution of the employment (including details on extent and duration of employment) and purchasing strategy to

ISSUE	PROJECT ACTIONS
	all project affected settlements, at least one month prior to the date of recruitment. • the employment and purchasing strategy to be publicised to sub-governors of districts along the pipeline route and in Adana and Yumurtalik districts. All governors in Turkey will also be informed.

16 CUMULATIVE IMPACTS

16.1 INTRODUCTION

16.1.1 Definitions of cumulative impacts

The IFC Procedure for Environmental and Social Review of Projects [Ref 1] states that environmental assessment includes consideration of:

> *"… cumulative impacts of existing projects, the proposed project and anticipated future projects."*

With regard to qualifying the spatial and temporal relationships of the subject project activities (i.e. those for which the assessment is being performed) and potential future projects, the Procedure states that:

> *"Assessment of cumulative impacts would take into account projects or potential developments that are realistically defined at the time the environmental assessment is undertaken, where such projects and developments could impact on the project area".*

EC Guidance on EIA [Ref 2] states that:

> *"The assessment of …cumulative impacts …. should not be thought of as a separate stage in the EIA process. Indeed the assessment of such impacts should be an integral part of all stages of the process."*

Cumulative impacts are generally impacts that act with others in such a way that the sum is greater than the parts. This is not always the case - sometimes they will simply be the sum of the parts, but that sum becomes significant. In general, several types of cumulative impacts of relevance to the BTC Project can be defined. These are outlined in Box 16.1 below.

Box 16.1 Types of Cumulative Impacts Relevant to the BTC Project

***Accumulative*:** the overall effect of different types of impacts at the same location (for example, fugitive dust emissions, construction noise and construction traffic).

***Interactive*:** where two different types of impact (which may not in themselves be important) react with each other to create a new impact (that might be important) (eg water abstraction from a watercourse might exacerbate the impacts caused by increased sediment loading).

***Additive*:** where impacts from the primary activity (ie the construction of the BTC Pipeline) are added to impacts from third party activities (eg other major projects in the vicinity of the BTC Project which are already occurring, planned or may happen in the foreseeable future).

It should be noted that the IFC Procedure defines cumulative impacts in the sense of additive impacts of the primary activity and third party activities.

16.1.2 Overview of methodology

The approach taken in the EIA and reported in Section 6 of the EIA Report facilitates the identification of the first two types of cumulative impacts. The linked tables and maps (presented in the Supplements to Volume 2) detail environmental and social baseline, potential impacts, mitigation measures and residual impacts as they occur along the route. There were three principal reasons for taking this approach:

- It enables all the impacts occurring at a particular location to be identified.

- The mitigation measures can be easily transferred to the 'alignment sheets' used by the Contractor in construction planning and design – in this way, mitigation measures identified in the EIA process are carried through to the construction specifications in an efficient, geographically-focused way that lends itself to the management of cumulative impacts.

- It allows cumulative impacts on, for example, a particular settlement or on a particular ecological resource to be readily identified. This will assist in focusing future consultation with stakeholders along the route. It also allows the ready identification and presentation of impacts where there is an interaction between different environmental aspects.

Similar considerations applied in the treatment of the proposed BTC Marine Terminal so that, for example:

- air quality impacts due to BTC Marine Terminal operation took account of all other major influences on air quality;

- fisheries and livelihood assessments of the BTC Jetty security exclusion and manoeuvring zones considered other developments within a 10km radius of the proposed BTC offshore Marine Terminal.

The approach adopted was underpinned by the application of the same assessment criteria to the various environmental and social aspects as are presented and described in Section 3.

The remainder of this section of the EIA Report deals with additive cumulative impacts, as set out in the IFC Procedure, which states that an EIA includes consideration of the cumulative impacts of "existing projects, the proposed project and anticipated future projects".

The basic approach used in the assessment was to look at potential cumulative impacts at several levels as follows:

- **Global Level:** the assessment of cumulative global level impacts has focused on greenhouse gas implication. The BTC Project will emit CO_2 and this has been quantified in terms of its contribution to global anthropogenic emissions.

- **Regional:** the BTC Project will be one of several linked and similar energy projects in the Western Caspian, South Caucasus and Eastern Mediterranean region. The assessment has looked at these from a macro socio-economic and environmental perspective, drawing on a separate piece of work entitled 'BP Azerbaijan: ACG, BTC and Shah Deniz Projects – Economic, Social and Environmental Review in the National and Regional Context' [Ref 3].

- **National Scale:** the assessment has addressed certain cumulative environmental issues (especially those with a transboundary consideration) and cumulative socio-economic issues within a national context.

- **Route level/marine terminal area level:** impacts were examined systematically in two phases:
  (i) screen other projects with which there is the potential for cumulative impacts;
  (ii) to scope those environmental and social aspects for which there is the potential for cumulative impacts between BTC and other projects.

The approach is described further in Section 16.5.1.

Further information on the methodology applied to each level of assessment is provided in the sections that follow.

16.2 GLOBAL LEVEL CUMULATIVE IMPACTS

The Project will contribute to global warming through emissions of so-called greenhouse gases (GHGs). The GHGs of relevance to the BTC Project are carbon dioxide (CO_2), methane (CH_4) and nitrous oxide (N_2O), all associated with combustion processes. The concept of a global warming potential (GWP) has been used to enable different GHG to be compared to each other and expressed in CO_2-e (Carbon dioxide equivalents). The GWP factors reflect the different extent to which gases absorb infra-red radiation and the differences in the time scales on which the gases are removed from the atmosphere. The GWP is used in the National Communications required by the UN Framework Convention on Climate Change (UNFCCC).

The Kyoto Protocol has adopted GWPs (with 100-year time horizon) as the basis for defining equivalence between emissions of different greenhouse gases during the 2008-2012 commitment period. Emissions of greenhouse gases (CO_2-e) are thus given by using the GWP as weighting factors for the emissions of carbon dioxide, methane and nitrous oxide:

$$CO_2\text{-e} = \text{carbon dioxide} + 21\ (\text{methane}) + 310\ (\text{nitrous oxide})$$

Although GHG emissions will occur during construction, the bulk of emissions will occur during the operational phase of the Project (see Appendix B2, Air Quality Modelling). The main sources will comprise:

- Exhaust from pump drivers at the four pump stations. This will comprise a total of 448 776 tonnes per annum (tpa) of CO_2 when the pipeline is operating at full capacity (and assuming no downtime). Once allowance is factored in for emissions of methane and nitrous oxide,CO_2-e emissions will comprise a total of 450 000 tpa.

- At the BTC Marine Terminal, there are two principal sources of GHG emissions. The enclosed groundflare will, at full capacity with no down-time, emit 152 450tpa CO_2. Tanker traffic within the vicinity of the Jetty is estimated to account for a further 1200tpa CO_2. These emissions combined are estimated to comprise a total CO_2-e of 154 000 tpa.

Total GHG emissions from the Project, when operating at full capacity with no down-time, will therefore comprise approximately 604,000tpa CO_2-e. The Government of Turkey (State Institute of Statistics) forecasts national GHG emissions in year 2005 (when BTC operation is scheduled to commence, but at reduced throughput) of 578.5 million tpa CO_2-e [Ref 6]. The

UNFCCC forecast world-wide GHG emissions in year 2010 (when BTC operation is scheduled to have reached full capacity) of 38 262 million tpa CO_2-e [Ref 7].

Based on the Government of Turkey's forecast for 2005, the BTC Project GHG emissions represent some 0.10% of Turkey's total CO_2-e emissions; this represents a Minor to Moderate impact when judged against the threshold criteria established in Section 3.8.7.

In international terms, the BTC Project in Turkey will contribute approximately 0.0016% of UNFCCC's forecast of global anthropogenic emissions of CO_2-e. While this can be regarded as an insignificant figure in itself, the Project has sought to minimise CO_2-e emissions (and those of other greenhouse gases). Efficiency (resulting in least CO_2-e emissions per unit of power generated/fuel combusted) was a key factor in selecting pump drivers. While the enclosed ground flare at the marine terminal comprises a significant source of CO_2-e, the alternative was to emit VOCs at a level deemed inappropriate in the context of local air quality.

16.3 REGIONAL LEVEL CUMULATIVE IMPACTS

The assessment of regional level cumulative effects on the natural and social environment pertains to all regional activities directly and indirectly related to the BTC Project. This includes the development of the Azeri-Chirag-Gunashli (ACG) fields and other oil fields in the Caspian, the construction of the overall transportation system and the shipment of the product through the Mediterranean Sea (see Figure 16.1). Geographically, this includes the Caspian, the Caucasian belt and Southern Russia, the Black Sea and Turkey. Existing pipelines in the region, although not included as part of this ultimate assessment, are indicated in Figure 16.1 and are described in Sections 16.3.3 – 16.3.7. These include the Blue Stream Natural Gas Pipeline (NGP), the Northern Route Export Pipeline, the Western Route Export Pipeline, the East Anatolian NGP and the BOTAŞ Oil Pipeline.

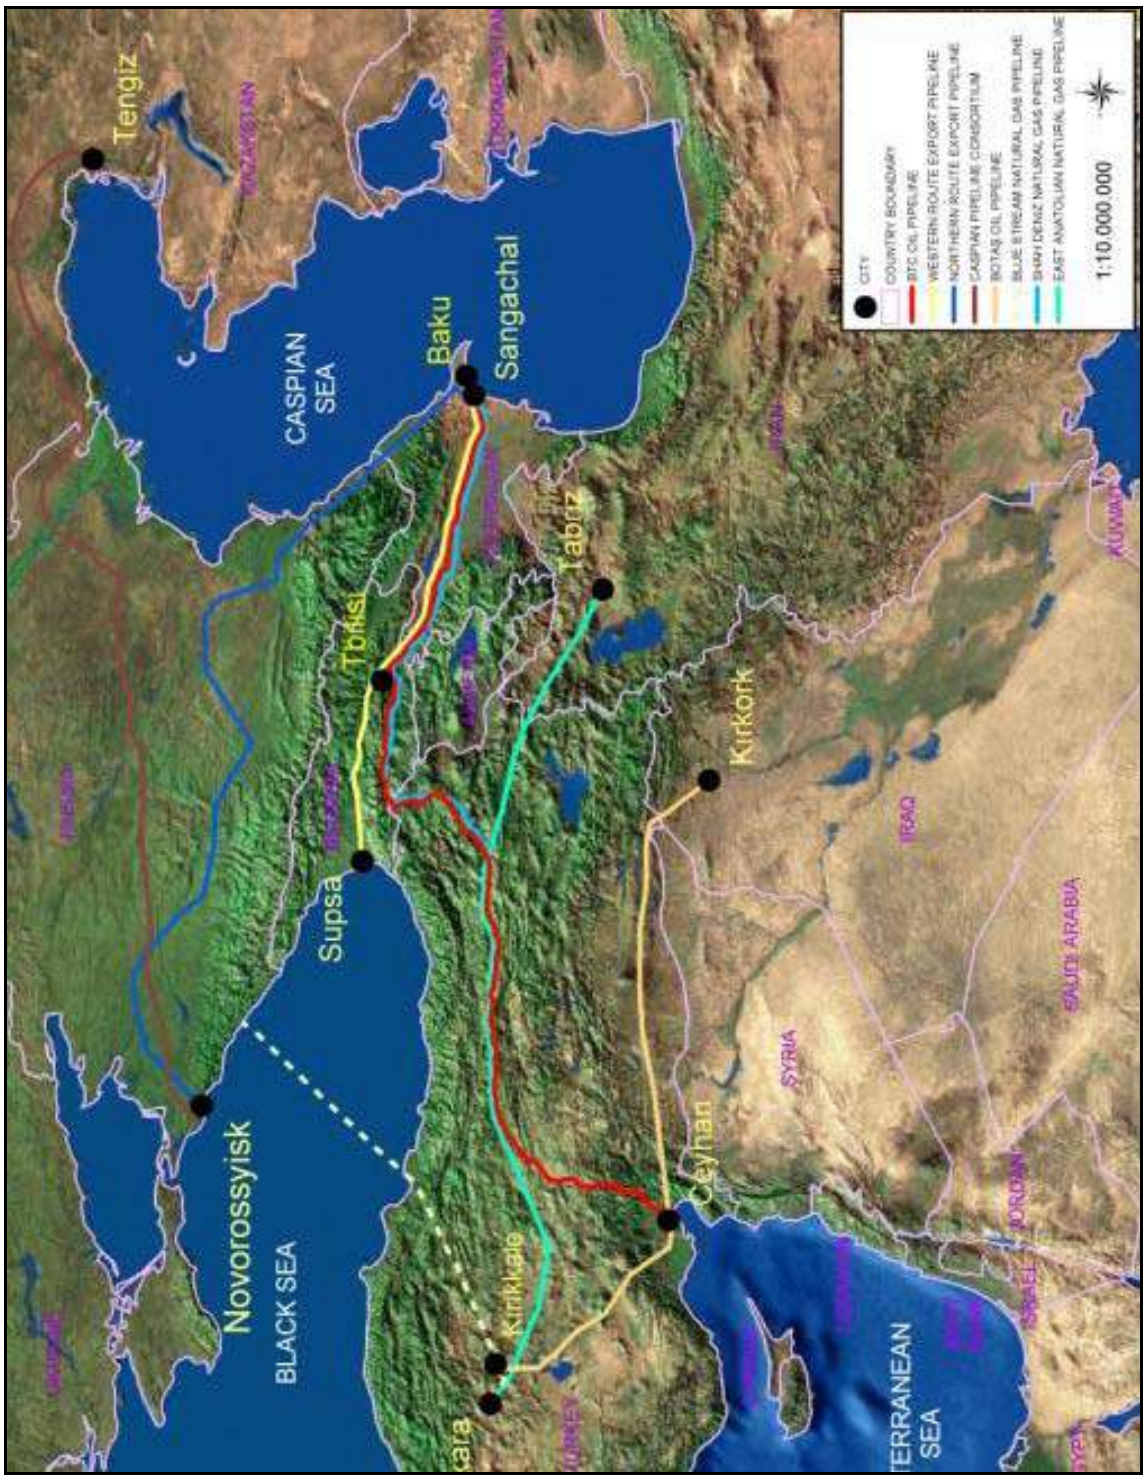

Figure 16.1 BTC Pipeline in Relation to Other Export Pipelines in the Region

16.3.1 Azeri-Chirag-Gunashli (ACG) development

The ACG Project consists of the development of the Azeri Chirag and shallow water Gunashli oil fields, offshore off Azerbaijan. One production platform (Chirag 1) is currently producing approximately 120,000 barrels of crude oil per day, which is transported by offshore pipeline to the Sangachal Terminal for processing, then primarily exported via the Western Route Export Pipeline (WREP) to Supsa on the Black Sea coast of Georgia and then by ship to international markets. A portion may also be exported by the Northern Route Export Pipeline (NREP) to Novorossisk on the Russian Black Sea Coast for further shipment. The future expansion of the ACG Project consists of three elements described below:

- Phase 1: Development of offshore;
- Phase 2: Full Field Development of the ACG field;
- Phase 3: Development of the Deep Water Gunashli field.

16.3.2 Shah Deniz Project and the South Caucasus Pipeline

The Shah Deniz Project involves the extraction of gas from offshore deposits in the Caspian Sea and exporting the gas to Turkey through Azerbaijan and Georgia. The gas will be used in Turkey to power energy plants in currently underdeveloped areas. A total of 8.2 billion m^3 of gas per year over a 30 year period will be extracted. Of these, 1 billion m^3 per year will remain in Azerbaijan, 0.6 billion m^3 per year will be delivered to Georgia, whilst the remaining 6.6 billion m^3 per year will be delivered to Turkey.

The gas will be pumped through the South Caucasus Pipeline (SCP) from Azerbaijan through Georgia to a delivery point in Turkey from where it will be distributed to users in Turkey by BOTAŞ.

16.3.3 Northern Caspian oil fields and the CPC Pipeline

Whereas the Shah Deniz and ACG projects originate from the Southern Caspian offshore fields, significant hydrocarbon production takes place in the Northern section of the Caspian Sea in Kazakhstan and Russia. Existing oil fields such as the onshore Tengiz facilities in Kazakhstan and large offshore fields both in Kazakhstan and Russia have the capacity to increase the current oil and gas production in the region. The expectation is to grow this production to 700,000 barrels per day by 2010. Tengiz crude oil is transported by a variety of means, including pipeline, rail and barge. Principal destinations include the Black Sea ports of Odessa, Feodosia and Batumi.

The operators of the Tengiz oil field have, however, recently commissioned the CPC (Caspian Pipeline Consortium) Pipeline. At full regime, this pipeline will have the capacity of transporting approximately 1.5 million barrels of crude oil per day. The pipeline ends at Novorossyirsk on the Black Sea from which crude oil is either shipped to Western markets on oil tankers through the Bosphorus or piped to European refineries through the Central European pipeline systems. It is expected that the CPC pipeline will be used for export from other oil fields in the Northern Caspian Sea, currently in their early stages of development.

16.3.4 Blue Stream Natural Gas Pipeline

The Blue Stream Natural Gas Pipeline (NGP), currently under construction is a gas export system from the Russian Federation to Turkey. The project relies on the construction of a sub-sea pipeline through the Black Sea. Its aim is to provide Turkey with a reliable supply of natural gas to meet the expected increased demand for power generation.

Currently published figures indicate that the Blue Stream pipeline will carry approximately 16 billion m^3 of natural gas per year from Russia to Turkey.

16.3.5 The Western and Northern Route Export Pipelines (WREP and NREP)

Two pipelines were initially constructed by the Azerbaijan International Operating Company (AIOC) to export oil from the early production activities carried out by the consortium in the Caspian. The pipelines, known as the NREP and WREP are currently in operation and transport 10,000 and 115,000 barrels of oil per day respectively.

The BTC Pipeline will be constructed mainly along the same route as the WREP within Azerbaijan. There will be no cumulative impacts as a result of the NREP and BTC Pipeline Projects in Turkey.

16.3.6 East Anatolian Natural Gas Pipeline (NGP)

With respect to the section of the BTC Pipeline in Turkey, the proposed pipeline runs parallel to the existing East Anatolian NGP for about 40% of the route in the central section between the cities of Erzurum and Sivas (see Figure 16.1). The NGP was constructed by BOTAŞ between 1999 and 2001 and commenced operations in September 2001. The NGP transports gas in Turkey from Dogubeyazit to Ankara.

16.3.7 BOTAŞ Oil Pipeline

The Iraq-Turkey Crude Oil Pipeline System transports the oil produced in Kirkuk and other areas of Iraq to the existing BOTAŞ Ceyhan Marine Terminal. The pipeline system, with an annual transport capacity of 35 million tonnes, came into operation mid 1977. The capacity of the line was increased to 46.5 million tonnes per annum through the First Expansion Project, the construction of which was started in 1983 and completed in 1984. With the completion of the Second Pipeline, which is parallel to the first one, the annual capacity reached 70.9 million tonnes as of 1987.

16.3.8 Assessment of regional impacts

As stated earlier, the assessment of regional level cumulative impacts has been carried out as part of a wider regional study [Ref 3]. The assessment, commissioned by BP on behalf of the BTC Co, provides advice (to BP and other interested parties) on steps required to enhance the sustainable development opportunities presented by the projects and to minimise any risks that they present.

The Review concluded that the ACG development, BTC and South Caucasus projects will have a significant effect on the development of Azerbaijan and Georgia primarily because of their size in relation to the rest of the economy. Due to the strength and size of the Turkish economy, the relative contribution of these developments will be smaller. The extent to which the projects contribute to sustainable development depends largely on the decisions taken by the government, especially concerning revenue use. The Review concluded that the major economic and socio-economic implications of the projects are expected to be in Azerbaijan and Georgia.

Poverty and inequality, corruption, human rights and conflict are issues in each of the three countries to varying extents. There are initiatives by governments and the international community to reduce poverty, to bolster human rights and to resolve the several 'frozen' conflicts in the region. There is scope for the projects to contribute positively to these issues, by applying high standards to the way in which projects are designed, built and operated and by engagement in the wider processes. Several important steps have been taken in the design stages of the projects in relation to construction, operations and engagement.

From a regional environmental perspective, the Review concluded that the projects would facilitate the large-scale introduction of international standards for health, safety and environmental protection.

16.4 NATIONAL LEVEL CUMULATIVE IMPACTS

16.4.1 Environmental

Overall emissions of NO_X in Turkey are 911,000 tonnes per annum. NO_X is a transboundary pollutant in that it contributes to acid deposition and, when mixed with Volatile Organic Compounds (VOCs), ground level ozone formation. The BTC Project in Turkey adds an increment of 0.09% to this total and therefore makes a negligible contribution in terms of cumulative impact.

Owing to the use of low sulphur fuel gas, emissions of SO_2 from pump stations are minimal. SO_2 from the BTC Marine Terminal (principally on-site tanker inert gas plant) is 7 tonnes per annum. Overall emissions of SO_2 in Turkey are 1,347,000 tonnes per annum (1999) and SO_2 is also a transboundary pollutant contributing to acid deposition. The BTC Project in Turkey adds an increment of 0.000006% to this total, and therefore makes a negligible contribution.

Since the BTC sources will be spread out along a >1,000km pipeline and that acid deposition problems for vulnerable habitats is not a commonly reported issue in Turkey, this is unlikely to contribute even in a minor way to existing problems.

16.4.2 Socio-economic

The cumulative socio-economic impacts resulting from the BTC Project, South Caucasus Pipeline (SCP) (also referred to in Turkey as the Shah Deniz Gas Pipeline) and other proposed development projects (or those currently under construction) will, if well managed, provide an overall increase in wealth and access to livelihood opportunities for the national population. Hence, the effect will be positive. The main national-level benefits will be improved infrastructure and increased government revenues from transit of oil and gas and taxes, all of which should contribute to reducing the national debt and increasing opportunities for investment and employment. Realisation of these major projects will also enhance Turkey's strategic geopolitical positioning.

In addition, provided local workers are used wherever possible, the skills base within the national population should increase, providing a more skilled workforce for future projects and increasing employment opportunities for those benefiting from skills enhancement either within Turkey or abroad. Furthermore, if goods and services are sourced locally (ie within Turkey), the effects on indirect employment and cash flows into the local economy should be beneficial. However, for these benefits to impact more than the project affected settlements, effective 'trickle down' has to occur in terms of revenues generated into the national economy. Whether or not this takes place will depend on the management decisions taken by the Turkish Government.

16.5 ROUTE LEVEL CUMULATIVE IMPACTS

16.5.1 Introduction and assessment criteria

The previous sections of this EIA have addressed the construction of the BTC Project. However, the Project is being constructed in close proximity to a number of proposed projects. Clearly there is potential for a large number of planned developments in the vicinity of the BTC Project, many of which will be small and inconsequential in the context of potential cumulative impacts associated with the BTC Project.

In determining where to focus the attention of the cumulative impact assessment of the BTC Project in combination with other projects, a screening approach has been adopted whereby the following criteria have been applied:

1. Distances have been set for different environmental and social aspects for which there is a reasonable likelihood for overlap between the BTC Project and one or more of the identified projects in terms of their construction footprint, including for example, noise footprint, operational air quality footprint, local workforce requirements, expropriation of land etc (see Table 16.1 below). For screening, the largest separation distance was taken as the starting point to identify other projects for the cumulative impact assessment.

2. A search was then carried out to establish which projects were of significant magnitude and complexity so as to require Ministry of Environment approval, and thus an EIA. Setting this as a criterion had the added advantage that data from third parties would be available for the proposed project where EIAs had been completed.

3. Proposed or planned projects, which may be developed sequentially to the BTC Project, were also investigated. However, such projects were generally in an early stage of conceptual planning and would be required to accommodate the BTC Project as part of the existing planning baseline. Nevertheless, reference to such potential sequential impacts is made in this section where the cumulative effects are likely, or are perceived to be significant.

4. Finally, respective project schedules were examined, particularly for overlapping construction phases, where impacts to many aspects are often concentrated and more difficult to manage.

Table 16.1 Spatial Criteria for Screening and Scoping Cumulative Impacts

Aspect	Spatial criteria for geographic separation between two projects/ receptor zones within which cumulative impacts might be experienced
Soils	• 100 m separation.
Landscape and visual	• As for soils for pipeline construction. • 2km for large scale prominent operational AGIs.
Water Quality/ Watercourse disturbance	• A stream connecting both projects up to a separation of 4km.
Groundwater	• Projects in the same unconfined aquifer up to a 4km separation.
Ecology	• 500 m for fauna disturbance. • 100m for habitat damage.
Noise	• 1km separation.
Air Quality	• Dust – 250 m separation. • Operational emissions (eg of NOx) – 2km separation.
Traffic	• Shared access roads through same community – ie road used by BTC Project and other projects for access – up to 10km separation between projects.
Cultural Heritage	• Both projects impact the same receptor – reasonable separation criteria of 200m.
Construction Camps	• If more than one construction camp is located within 5km of a settlement.
Resource Ownership or Resource Use	• For pipeline projects, if land within a 2km radius of a single settlement is intersected (and expropriated) by more than one development. • For other projects, if land belonging to a single settlement is expropriated for more than one development – up to 10km separation between projects, or: • If resources owned or used by a settlement are impacted upon by more than one development - up to 10km separation between projects.
Employment	• If a settlement falls within the employment sourcing area for more than one development - up to 10km separation between projects, for unskilled labour and within the same district or province for semi-skilled and skilled labour.
Infrastructure and Services	• For pipeline projects, if a settlement falls within a 4km corridor of more than one pipeline project. • For other projects, if a settlement falls within the area of impact of more than one project – up to 10km separation between projects. • Shared access roads through same settlement – ie road used by BTC Project and other projects for access – up to 10km separation between projects.
Community Relations	• For pipeline projects, if a settlement falls within a 4km corridor of more than one pipeline. • For other projects, if a settlement falls within the area of impacts of more than one project - up to 10km separation between projects.
Safety of Residents	• Shared access roads through same settlement – ie road used by BTC Project and other projects for access – up to 10km separation between projects.

For SCP-BTC cumulative impacts, the above criteria were applied conservatively by adding a 1km margin to all the separation distances to allow for modifications to the final route of the SCP during detailed design, since the conceptual route is based on a 2km corridor. The above

separation distances also applied to off Right of Way (RoW) activities such as construction camps and laydown areas.

Based on the relative locations of these developments, the following combination of projects is likely to result in cumulative impacts with BTC:

- construction of the BTC Pipeline and the SCP (including the SCP Custody Metering Station);
- construction of the BTC Pipeline, SCP and Koroglu Dam;
- construction of the BTC Pipeline, BTC Marine Terminal and other developments within a 10km radius of the proposed terminal, comprising Sugozu Power Plant and Sanko Holdings Petrochemical Plant.

These are discussed in more detail in the following sections.

In addition to its use as a screening aid, Table 16.1 has also been used to scope potential impacts. For example, the cumulative impact assessment may look at two projects in combination but would not necessarily look at all the environmental and social aspects. For example, if the projects are further than 10km apart then the only socio-economic aspects worthy of consideration would be employment, procurement and, possibly, infrastructure provision, whereas for a separation of 100m all aspects would be examined for which receptors are actually present. Thus, for example, the cumulative impacts of construction camps are considered for the BTC Marine Terminal and other developments in the area as more than one construction camp falls within a 5km radius of a settlement. However, this overlap does not occur for the BTC Pipeline, SCP and Koroglu Dam and not part of this cumulative assessment.

16.5.2 Existing projects in the immediate vicinity of the BTC Project

The East Anatolian NGP was constructed by BOTAŞ between 1999 and 2001 and commenced operations in September 2001. The NGP transports gas in Turkey from Dogubeyazit to Ankara. As the NGP is in existence, it forms part of the environmental baseline in which the BTC Project will be constructed and was assessed as such in the EIA. Locations and/or circumstances where the existence of the NGP could affect the potential impacts of the BTC Project are reported in the Impact Tables presented in Section 6 and Supplement 1 of the EIA Report.

Similarly, the assessment of the BTC Marine Terminal (see Sections 12 and 13) has taken account of the existing BOTAŞ Marine Terminal and other coastal development in Iskenderun Bay that form the current baseline.

The cumulative impacts assessment reported in this section of the EIA Report therefore focuses on the interaction of the BTC Project and *"**potential** developments that are realistically defined at the time the environmental assessment is undertaken, where such projects and developments could directly impact on the project area".*

16.5.3 Construction of the BTC Pipeline and the SCP

16.5.3.1 Details of the proposed SCP development

The South Caucasus Project involves extracting gas/condensate from offshore deposits in the Caspian and exporting it through the SCP to Turkey, via Azerbaijan and Georgia. Some gas will be taken in Georgia, with the remainder going to users in Turkey via a tie-in to the NGP near Horasan. The gas will be distributed by BOTAŞ. The route corridor of the SCP in Turkey, and its relationship to BTC, is shown in Figure 16.2.

SCP is at the conceptual design stage and this has produced a centreline based on a 2km design corridor. This is viewed as an adequate allowance for altering the route of the pipeline to avoid currently unknown constraints, which could comprise geohazards, ecology, archaeology or social. What this does mean is that SCP's centreline could move up to 1km closer to BTC. This has been allowed for in the screening and scoping exercise described above. Detailed design is yet to proceed and this will lead to a final working corridor. The approximate length of the route in Turkey is 224km. As well as the pipeline itself, there will be a Fiscal Metering Station 1km inside the Georgian border and a Compressor Station at approximately KP40.

The following issues are of relevance to potential cumulative impacts with the BTC Pipeline.

- The construction phase for both will be broadly concurrent (see Table 16.2). This does not mean that BTC and SCP construction will simultaneously proceed in the same direction (the worst case for some potential cumulative construction impacts although the best case for potential seasonal ecological constraints). However, since the detailed construction schedules have not been developed, this cumulative impact assessment assumes the worst case.

- There will be an off-take from the Fiscal Metering Station to supply the BTC pump station (PT1) nearest to the Georgia border. Its construction will be broadly concurrent with that of BTC and SCP.

- Two further off-takes, to supply gas to Ardahan and Kars, will be provided at a later date outside the construction timescale of BTC and SCP.

- Off-takes will comprise small diameter pipelines of 6 to 8 inch diameter. Typically these require a working width of 7-11m depending on such matter as terrain and presence of woodland/sensitive areas.

- On average there is a 20km separation between BTC and SCP.

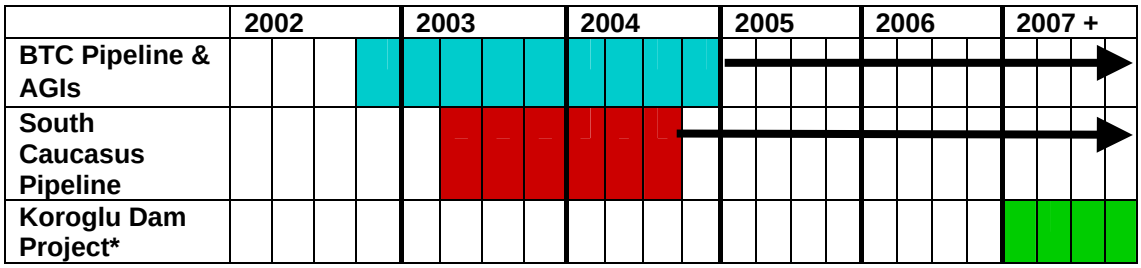
- There are two sections where the routes come especially close together: from the Georgian border to the Fiscal Metering Station and at around KP 104-108, northeast of Kars (see Figure 16.2). The basic principle is to maintain a 250m separation between the final centrelines. Where this is not possible, near the Georgian border, the separation will be at least 30m to ensure that corridors do not overlap.

- The section between the Fiscal Metering Station and the Georgian border will not be constructed concurrently with BTC. This section will be completed to the same schedule as the SCP in Georgia (ie it will follow by one year). Prior to SCP gas being available, flow in the Turkish section of SCP will be in reverse, using gas from the NGP to supply PT1 for BTC operation.

- There will be a single construction contract and construction will most likely be with two spreads (along with work crews at the Fiscal Metering and Compressor Stations). Construction camp locations are some way from being decided but the most likely locations are one at the Compressor Station site near Hanak and another near to Horasan or Sarikamis.

Table 16.2 provides a summary of the schedule details for the BTC Pipeline, SCP and the Koroglu Dam Project (the latter is discussed in Section 16.5.4).

Table 16.2 Summary of Schedule for BTC Pipeline, SCP Pipeline and Koroglu Dam Project



* The construction schedule for the Koroglu Dam has not yet been finalised, but is unlikely to begin within the next 5 years.
** Arrows indicate project operation

16.5.3.2 Cumulative environmental impacts

Introduction

There are only two locations where the two pipelines will run in close proximity (within 2km):

- at the border between Turkey and Georgia (KP0-KP2);
- at the provincial border between Ardahan and Kars (KP104-KP108).

At the border crossing, the distance between the two pipelines has been defined by the BTC Co as 30m. Both pipelines will separate after the Custody Metering Station, located approximately 3km from the border. Hence, there will be a length of approximately 3km of the BTC Pipeline Route, which will be paralleled by the South Caucasus Pipeline. A 4km length of BTC Pipeline runs parallel to the SCP pipeline, separated by a distance of approximately 500m at the provincial border between Ardahan and Kars.

Although known or likely construction camp locations are sufficiently separate to exclude direct environmental cumulative impacts, the planning of materials and labour acquisition, transportation implications and the capacity of services and facilities will be a consideration both within this assessment and within the Contractors' mobilisation planning.

Construction impacts

The main potential cumulative impacts that could occur during construction are summarised in Table 16.3.

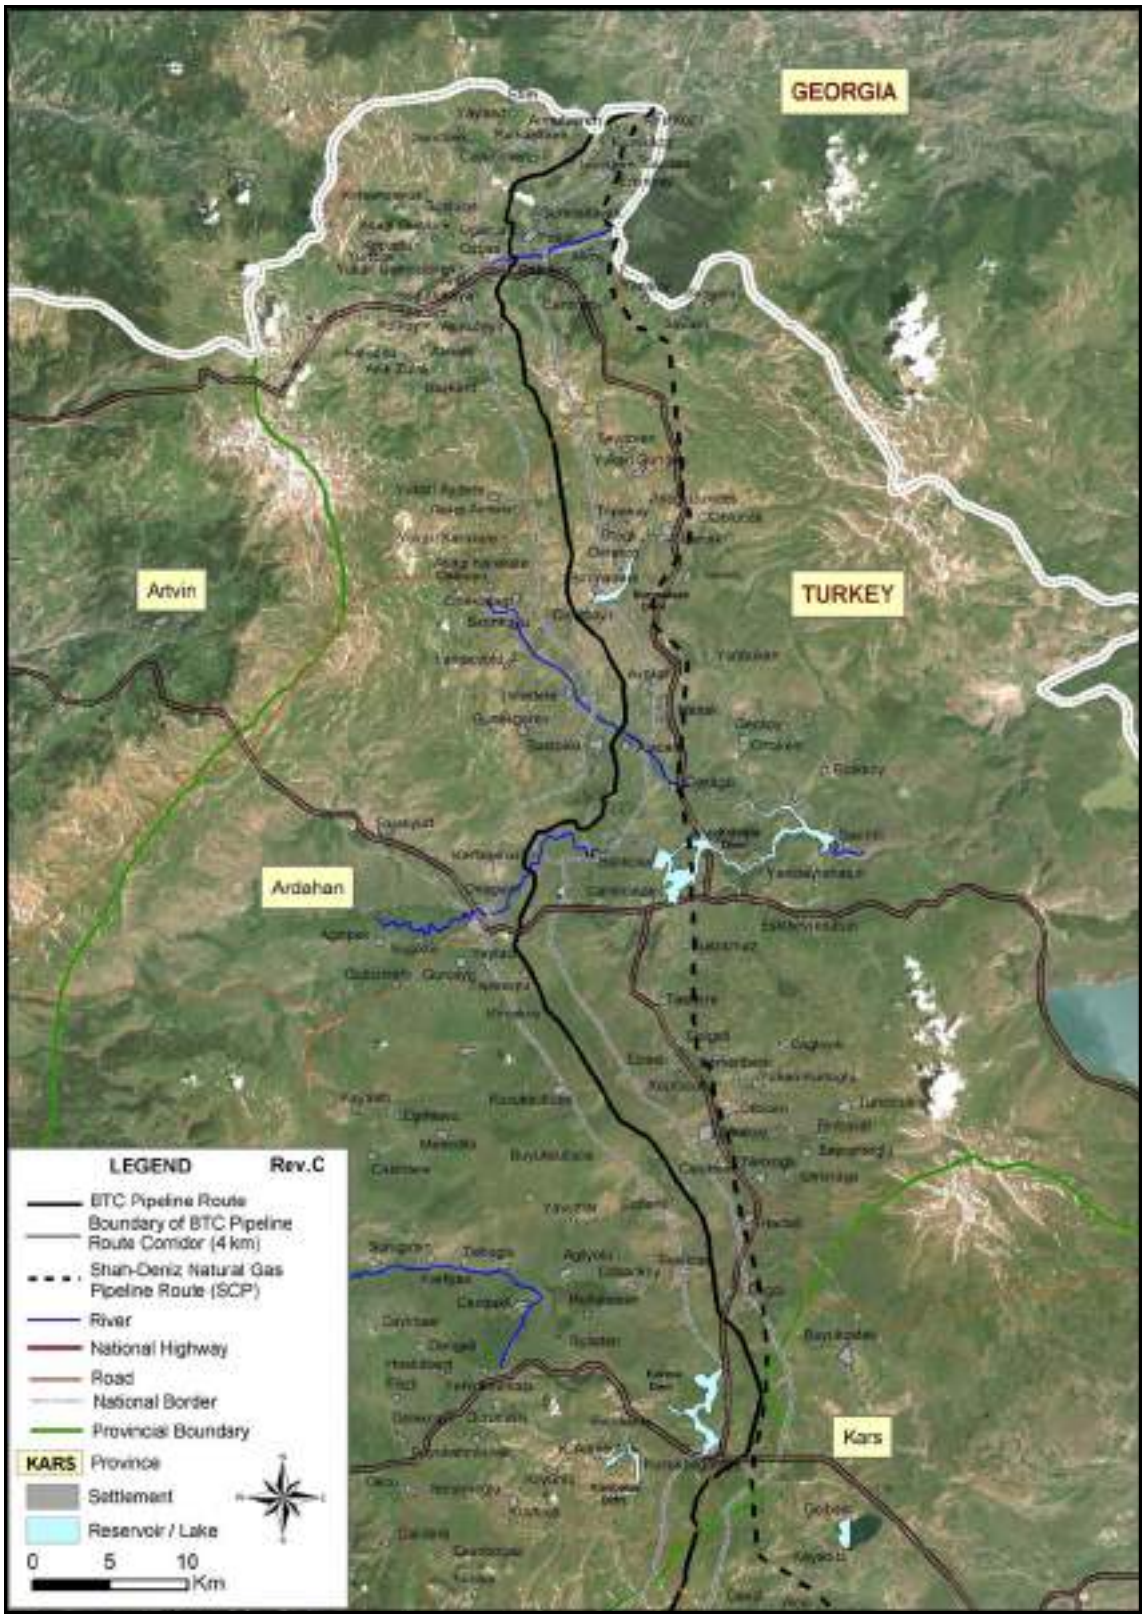


Figure 16.2 Location of BTC and SCP Pipeline Routes

Table 16.3 Cumulative Construction Impacts of the BTC and SCP Pipeline Routes

BASELINE	BTC RESIDUAL IMPACTS	CUMULATIVE IMPACTS
Map Number 1 KP 0-1.89		
Soils Between KP 0 – 2, soils are classed as Mesic Clayey-skeletal to Loamy-skeletal Typic Xerochrepts, are shallow, stony, and have a pale-brown to brown surface.	Where tuff is exposed potential major impacts on soil productivity could result (see also Section 15).	Should SCP expose tuff, leading to reduction in soil productivity, cumulative impacts would be major.
Landscape and Visual From entry point south of the Georgian border, landscape is unremarkable comprising gently rolling hills with market gardens and some grazing land. Field boundaries are well marked with mature hedges and wooden fences and some drystone walls. The route crosses c. 1km of irrigated agricultural land and pastureland. Terrain shows a steady increase of elevation from the Georgian border (elevation 1,232m) to base of mountain ridge about 10km south west (elevation 1,900m). It rises through steeply dissected ridges before becoming more undulating. Landscape sensitivity is relatively low.	Visual impacts will be generally short-term and minor due to the temporary nature of construction activities, though any remaining traces of the route will be visible to the residents of Turkgozu settlement.	Minor on the basis that SCP is reinstated to the same standard as BTC. Cumulative impacts are predicted to be minor.
Ecology Route crosses the Posof Wildlife Protection Area (KP10 - KP15), established primarily for the Caucasian Black Grouse (*Tetrao mlokosiewiczi*), a globally threatened species classified as Data Deficient and also a restricted range species. This section of the route crosses through cultivated land and scattered areas of deciduous forest. This area also supports a range of species including the Eurasian Brown Bear *(Ursus arctos)*.	Short-term disturbance as pipeline passes through only sparsely forested areas.	Where the SCP parallels the BTC Pipeline (ie at a distance of less that 100m) cumulative impacts will be minor, if the seasonal sensitivities and working method constraints adopted by the BTC Pipeline are equally applied to the SCP Project. If the construction activities of the two projects occur concurrently, major cumulative impacts can be expected unless close inter-project co-ordination and management is established. At greater separation distances, moderate cumulative impacts may occur through disturbance to two parts of the Reserve at the same time as refuge options for displaced wildlife would be restricted. It is essential, therefore, that the staggering of works be considered as part of overall joint working and cooperation.

BASELINE	BTC RESIDUAL IMPACTS	CUMULATIVE IMPACTS
Noise The settlement of Turkgozu (KP1) is located approximately 500 m east of the BTC Pipeline and 250 m east of the SCP pipeline. The settlements of Armutveren and Kumlukoz are located approximately 500m to the east of the BTC Pipeline and within 1.5km of the SCP pipeline.	Appropriate mitigation measures will ensure that impacts are minimised. Impacts are anticipated to be minor.	Mitigation measures will include staggered construction and additional mitigation in the form of acoustic screens. Cumulative impacts are predicted to be minor. It should be noted that the major noise impact to the village of Turkgozu would arise from the extended construction period associated with the SCP Custody Metering Station.
Map Number 4 KP 48.7-67.9		
Water Resources Potential impacts to watercourses are limited to the Cotsuyu River, which is crossed by the BTC Pipeline at KP50. The SCP pipeline then crosses the river approximately 5km downstream. The Cotsuyu River is an important ornithological area.	Construction of the river crossing will be avoided between April and the end of July in order to avoid bird breeding season, therefore only resulting in minor impacts.	The SCP crossing is also anticipated to result in minor impacts (assuming appropriate mitigation is adopted). The BTC crossing will not result in any incremental impact.
Groundwater The route passes over an unconfined aquifer (KP50). The same unconfined aquifer is also crossed by the SCP pipeline approximately 10km to the east.	Mitigation measures are designed to prevent significant impacts during construction. As such, impacts are predicted to be minor.	The impacts from the SCP project are also predicted to be minor, therefore overall impacts are predicted to be minor.
Map Number 7 (KPs104-108)		
Soils Sandy-skeletal Cryochrepts occurring on slopes at high elevations and comprising young, shallow soils. They are typically stony and have a pale brown to brown surface. They support upland grassy meadows.	Minor impacts except where tuff is exposed and soil productivity is reduced, in which case Major impacts would occur (see also Section 15).	SCP will double the size of the impact zone. Major impacts will result where tuff is exposed.
Ecology Aygir Lake, a large oligotrophic lake located about 8km east of Buyukbogatepe and c.8.7km west of the route is an important ornithological site supporting Velvet Scoter (nationally-threatened), one of Turkey's rarest breeding birds. The breeding status of these birds on, or around, this lake is unknown, but breeding is possible.	Minor disturbance impacts only will result since the most sensitive area will be avoided.	Although SCP passes closer to the site, cumulative impacts are predicted to be minor
Archaeology and Cultural Heritage Buyuk Bogatepe flat settlement lies within the 100m corridor (north of KP 108). Although no architectural remains were discovered, Roman ceramic shards were found on the surface at this site. This may, therefore, have been a rural Roman settlement. This site has not yet been registered by the MoC and is provisionally assigned the 3rd Degree site classification (see Section 5).	Pre-construction investigations will establish the full extent of the site; however it is currently expected that there will be only minor impacts, which will be restricted to temporary disturbance of the wider setting of the site.	Minor impacts since SCP is further from the site than BTC.

Generally the construction impacts will be minor and manageable. Where there is the potential for congestion and related impacts from construction traffic to settlements near or en route to the two pipelines, construction phasing will be carefully considered in order to minimise disturbance impacts. In particular, the settlement of Turkgozu is located in close proximity to the BTC Pipeline as well as the SCP pipeline and SCP metering station. The BTC Pipeline will be a minor factor in the overall cumulative impact of the three developments and as such, the predominant impact will be managed by the SCP Project.

Both projects will require natural resources, especially water and construction aggregates. Generally the projects are sufficiently separated that water abstraction will be from different watersheds and groundwater zones. The potential for cumulative impacts is, therefore, small.

Both projects are still developing construction aggregate requirements in terms of precise types, volumes and sources. The BTC Project is working on the basis that sites will be licensed and the Project can use the resource at a rate that will not compromise existing users. Should the Project require its own quarries, it will conduct EIAs and make formal applications for approval to the Turkish authorities. On the basis that the SCP operates to a similar standard the scope for cumulative impacts is small.

As well as requiring raw materials/natural resources, both projects will generate construction spoil and various other solid wastes. BTC wastes will be managed within the framework of the Waste Management Plan, but inevitably some wastes will require disposal. Implementation of the management plan sets a requirement that suitable waste disposal facilities will be identified. One criteria for their use is that the volume of BTC waste going to any one disposal location shall not exceed or compromise the capacity of the site.

The objective of this exercise will be to ensure there is no conflict with other users. BTC and SCP are likely to be relatively significant producers of waste and this may raise potential conflicts over waste disposal capacity. This will be addressed through an appropriate degree of collaboration in identifying suitable waste disposal sites.

The one area of Major cumulative impact is to soil. Managing the residual implication of the construction and reinstatement of the pipeline in tuff soils is described in Section 15. Although these impacts will endure beyond the short-term they will be reversible and may eventually be reduced to a Moderate level of impact.

16.5.3.3 Cumulative social impacts

Land ownership and use

There are four points along the BTC Pipeline and SCP routes where land belonging to a settlement will potentially be impacted upon by both pipelines. As highlighted previously, this is calculated based on a 2km radius to the east of the BTC Pipeline and 3km to the west of the SCP. Where this overlap occurs, the following settlements in Ardahan and Kars have been identified:

- In the vicinity of the border crossing, from KP1 to KP5, land belonging to Turkgozu, Armutveren, Kumlukoz, Incedere, Kayinli, Kalkankaya and Eminbey.

- At KP 45-50, land belonging to Avcilar, Hanak and Alaban.

- From KP 85 to KP 110, land belonging to Haskoy, Calabas, Haciali, Cobanli Dagci, Kucukbogatepe and Buyukbogatepe.

- AT KP 225-230, land belonging to Degirmenler and Azab.

Bearing in mind that construction of the BTC and SCP will be broadly concurrent (with the exception of the stretch between the Fiscal Metering Station and the Georgian border), the potential impacts associated with this additional expropriation include:

- larger area of disturbance to agricultural activities;
- creation of uneconomical units of land;
- decreased land productivity due to inadequate restoration measures;
- increased potential for a deterioration in community relations due to dissatisfaction with the land expropriation and compensation process.

However, both projects will be complying with World Bank standards on expropriation and compensation. Their respective land acquisition processes will therefore incorporate measures to address the social and economic impacts associated with land take. Internal and external monitoring will also be carried out, including procedures for addressing any feedback received, where appropriate. The consultation process inherent in these Plans will also ensure full understanding of the expropriation and compensation process, and will allow the affected owners to reach a mutually agreed compensation arrangements. This will assist in mitigating possible tensions associated with this process.

A positive cumulative benefit associated with expropriation for both pipelines is the additional clarification of land tenure status for land without legal title deeds (a common occurrence along the BTC Pipeline route). In order to award expropriation payments, such legal clarification is required. Clarifying land tenure status allows owners to use their land as collateral against which they can loan money to invest in improving their future livelihood. It also helps to prevent future conflicts from arising over land rights. During consultation, numerous land owners/users expressed eagerness regarding the compensation payouts, as this represented an opportunity to depart from low productivity agricultural activities.

Employment and provision of goods and services

Along the length of the BTC Pipeline and SCP, there are a number of locations where settlements fall within the sourcing radius for both pipeline projects. Preferential employment for unskilled labour (for both projects) is, however, most likely to go to those settlements whose land is expropriated by both projects. This is a factor of both distance and international standards of best practice, which encourage companies to maximise benefits to those most affected by a development.

However, numerous settlements meet other criteria for preferential employment for both projects, although the focus is more likely to be on semi-skilled and/or skilled employment. This includes: 1) settlements within a 10km radius of both projects; and 2) settlements within the districts and/or provinces traversed by both pipeline projects.

Other cumulative benefits include increased cash flow into the local economies (and associated knock-on effects) and opportunities for the provision of goods and services. In addition, workers who have experience on more than one project will be more attractive to future employers, and opportunities for training and learning new skills for those employed will be extended. These, together, will have a combined positive impact on the health of the local economy.

Increasing the extent and duration of temporary employment has a number of potential negative cumulative impacts. These include: 1) workers giving up their normal employment (formal,

self-employed or informal) for perhaps higher paid temporary employment during construction of the pipelines, resulting in a possible loss of longer-term livelihoods; 2) wage levels could increase where there is a shortage of labour, making for example the contracting of seasonal cultivators too expensive for local landowners; and 3) increased spending power of employees may temporarily increase the cost of local and regional supplies. These cumulative impacts are not expected to have a significant impact on local settlements.

Infrastructure and services

In accordance with international standards for best practice, measures will be adopted by both the BTC and SCP Projects to ensure that negative impacts to infrastructure and services are prevented or kept to a minimum. This includes: 1) commitments to self-sufficiency (in terms of service provision); 2) restoration measures to ensure that infrastructure, such as roads, are restored to at least their pre-construction condition; and 3) adequate warning for planned disruptions (where appropriate, this will include compensation, as determined in the land acquisition process). However, with projects of this scale it is likely that there will be instances when infrastructure or services are disrupted without notice or prior planning. Settlements that fall within the 'area of impact' for both the BTC Pipeline and SCP are therefore vulnerable to this occurring for both projects, whether simultaneously or staggered over time. This has implications for impacts on livelihoods as well as the cumulative 'nuisance factors' (traffic, noise, dust, disruption to infrastructure, construction workers along the working width etc) and resultant deterioration in community relations for both projects.

As discussed in earlier sections, unplanned disruptions to irrigation channels can have widespread impacts for numerous settlements beyond those located within the area of overlap for both projects. By way of mitigation, the community relations team for the BTC Project will identify all areas where irrigation networks could potentially be impacted by the BTC and Pipeline and SCP. These areas will be flagged for the construction teams and community relations teams of both projects. Specifically, the BOTAŞ CLO will notify authorities of affected settlements regarding occurrence of unplanned disruptions, as well as expected duration of disruption and measures to be taken to rectify incident. A complaints procedure will also be operated to allow for reporting and resolution of any grievances. Where appropriate, compensation will be provided for losses incurred, as determined by the land acquisition process. These settlements will also receive specific focus during the monitoring activities undertaken by the BTC Project.

Safety of residents

Cumulative safety risks during construction could potentially result from shared access roads and associated traffic hazards and from the dangers associated with an open trenching. In accordance with World Bank requirements, BOTAŞ (and the Construction Contractor) will be required to compile and implement a Traffic Management Plan (TMP) that addresses, among other issues, the safety risks associated with the construction traffic for the SCP. However, the mitigation measures included in the BTC TMP and Community Safety Management Plan are considered sufficient to address the cumulative traffic hazards of both projects.

Once the access roads for the SCP have been identified, the community relations team for the BTC Project will identify those areas of overlap and ensure that the affected settlements receive the required safety awareness training including specific meetings for women and children. This is particularly important in areas not accustomed to heavy traffic loads. These areas will be flagged for the construction teams and community relations teams of both projects. These settlements will receive specific focus during the monitoring activities undertaken by the Project.

In areas where the working widths of both pipelines are within 500m of one or more settlements, protective barrier fencing (sufficient to impede young children) will be erected along the full length of the relevant sections of trenches. Settlements within this area of potential impact will also be targeted for safety awareness training. In areas of danger to livestock, stock-proof fencing will be erected.

Community relations

As already highlighted in this section, a deterioration in community relations could occur as a result of the cumulative impacts associated with the BTC Pipeline and SCP. This would most likely be a result of: 1) dissatisfaction with the land expropriation and compensation process; 2) cumulative nuisance factors; and 3) unmet expectations regarding employment.

The cumulative employment associated with the BTC Pipeline and SCP is expected to increase the number of people employed and thus, the extent to which expectations are met. However, in instances where settlements (or individuals) in these 'areas of overlap' do not gain employment (or their expectations are not fully met), the potential exists for high levels of frustration and resentment towards those who succeed in getting jobs, and also towards the Project. This cumulative impact will be mitigated in part by the Employment Strategy for the BTC Project. This includes procedures for widespread publication of the extent and duration of employment opportunities, including notification of the priority to be given to project affected settlements. It is intended that this will assist in ensuring realistic expectations regarding employment on the BTC Project.

16.5.4 Construction of the BTC Pipeline, SCP and Koroglu Dam

16.5.4.1 Details of the proposed Koroglu Dam

The proposed Koroglu Dam is located within Ardahan province, approximately 8km east of the BTC Pipeline (in the vicinity of Kartalpinar) and is intersected by the SCP (see Figure 16.3). The dam is part of the Kura Project initiated by the General Directorate of State Hydraulic Works (DSI), the aim of which is to provide electricity to the region and to form a series of irrigation water reservoirs. The project will produce 443.4 GW of electricity annually and is predicted to increase crop yield in the Ardahan Plain.

The construction of Koroglu Dam will require the expropriation of 138ha of land. This is comprised of 2ha of residential land, 68ha of agricultural land and 68ha of forested land. Four settlements will require resettlement: Cayagzi, Altas, Balikcilar and Olcek. No date for construction (and thus resettlement) has yet been set, although it is unlikely to begin within the next five years (see Table 16.6for schedule summary).

The proposed location for the construction camp is within the dam area that will later be submerged. It is likely that the camp will be located near the dam wall, in the vicinity of Sevimli settlement. No additional access roads will be constructed for the Project. The Ardahan-Posof road, and local settlement roads will be used for construction vehicles. The project is expected to source unskilled labour from 'local settlements', although the specific sourcing areas and employment totals have not yet been defined.

16.5.4.2 Cumulative environmental impacts

The scope for cumulative impacts from the SCP and BTC Pipelines and the Koroglu dam is small as a result of the following factors:

- the BTC Pipeline is located approximately 8km west of the Koroglu Dam Project and the SCP;
- the construction phase of the pipelines will not overlap with that of the dam.

As such, no cumulative environmental impacts are anticipated.

16.5.4.3 Cumulative social impacts

Land ownership and use

Cayagzi is the only settlement that has land that will be intersected (and expropriated) by all three developments. In addition: 1) Cayagzi is one of four settlements that are due to be resettled for the construction of the Koroglu Dam; 2) Cayagzi falls just within the 2km radius of the BTC Pipeline; and 3) Cayagzi is directly adjacent (or dissected by) the centreline for the SCP. The significance of the associated cumulative impacts Cayagzi depends on the timing of the resettlement process. Currently, resettlement and construction of the Koroglu Dam has not yet been initiated. Should it occur *after* the construction of the BTC Pipeline and SCP, Cayagzi will experience expropriation of land twice prior to its actual resettlement. However, should resettlement occur *prior* to the expropriation activities for the pipelines, cumulative impacts will not occur, as resettlement will be a once-off activity and all land belonging to Cayagzi (including that required by BTC and SCP) would have been compensated for as part of the Koroglu Dam expropriation process.

However, assuming a worse case scenario, Cayagzi could potentially undergo expropriation activities for all three projects. Although a stringent expropriation and compensation process is expected to be applied to all three projects, there are a number of impacts that cannot be easily mitigated against. These include: 1) social disturbance and upheaval associated with consecutive expropriation processes; 2) impacts on levels of livelihoods due to decreasing land available for agriculture and limited alternative forms of livelihood (the potential for squandering of accumulated compensation therefore exists); and 3) anxiety and tensions developing within the Cayagzi, particularly if resettlement for the dam is authorised, but the date remains uncertain. These potential impacts could result in a highly sensitised population less tolerant of the nuisance factors normally associated with large-scale developments. The potential for outbursts is obviously heightened when a settlement is the recipient of nuisance factors (noise, dust, traffic congestion, disturbance from construction workers, unplanned disruptions) associated with three such projects. This scenario could have an impact on community relations for all three projects.

In order to manage the possibility of tensions developing, the community relations teams for the BTC and SCP projects will need to pay specific attention to Cayagzi. This will need to include regular briefings regarding construction activities, safety awareness meetings, opportunities for constant community feedback regarding concerns and suggestions for improvement, and implementation of measures to address unplanned disruption to infrastructure and services. These efforts will only be required if resettlement of Cayagzi occurs *after* the construction of the BTC Pipeline and SCP.

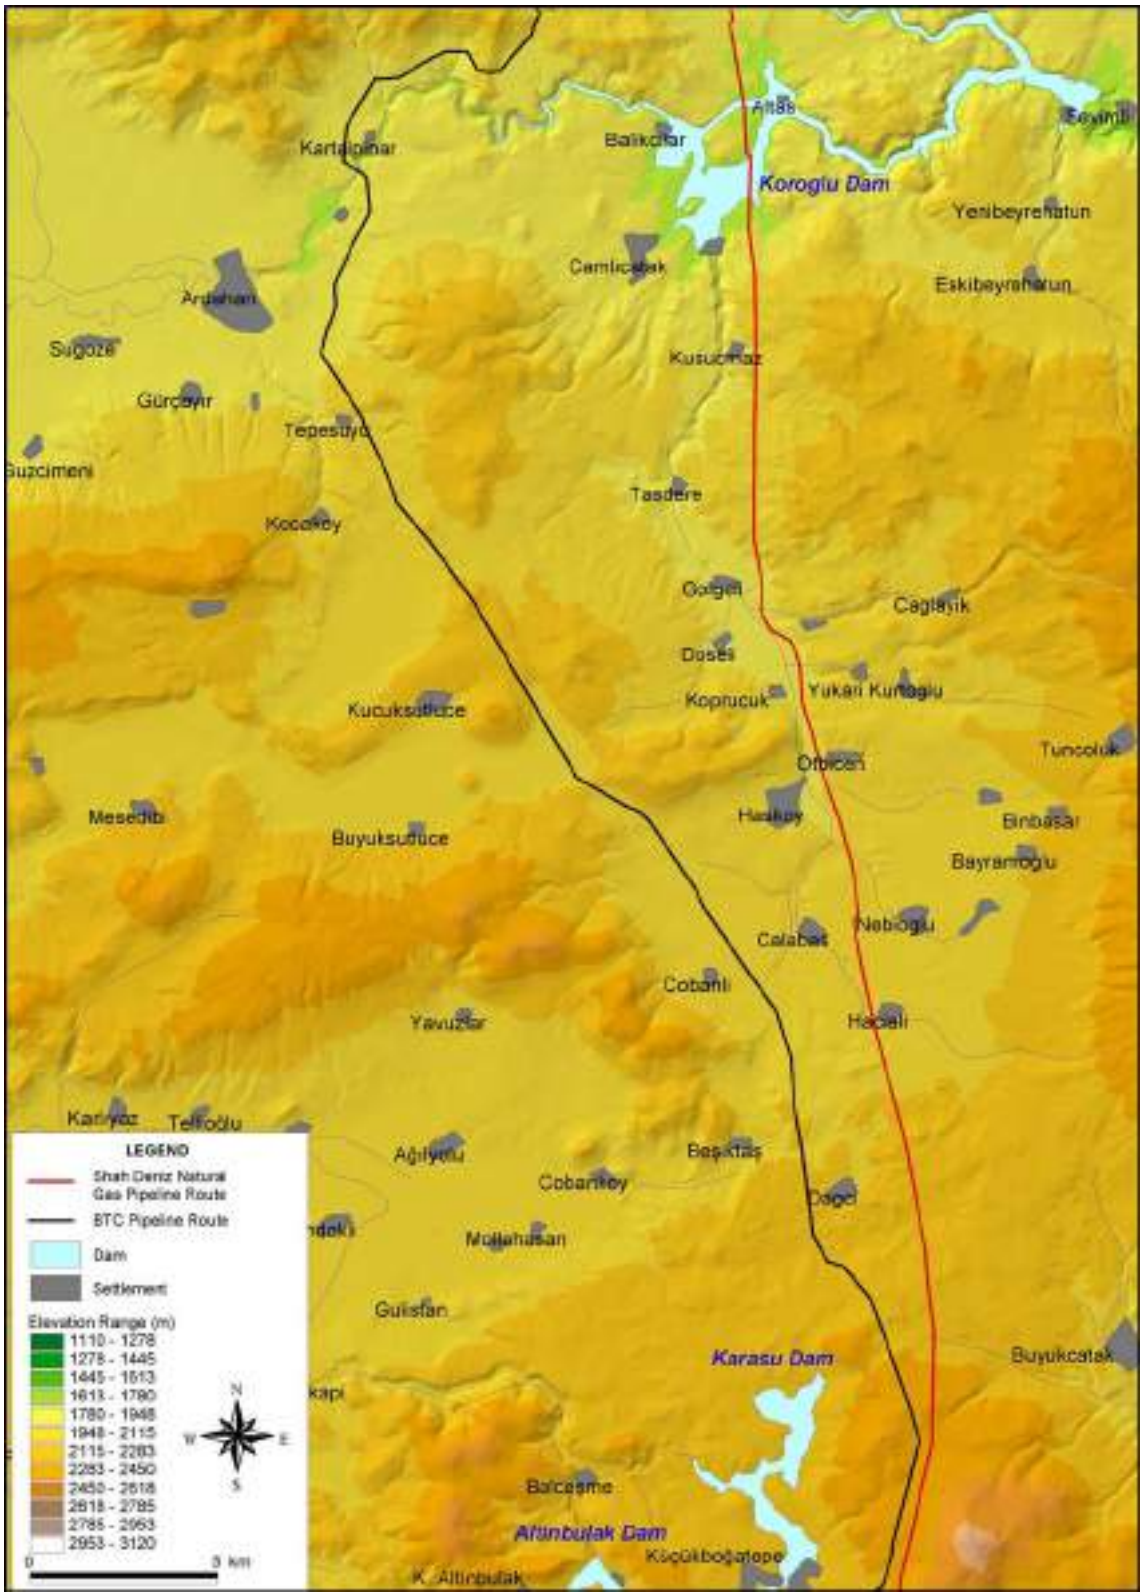

Figure 16.3 SCP (Shah Deniz) Pipeline and Koroglu Dam

Employment and provision of goods and services

Based on an assumed 'sourcing radius' of 10km for unskilled workers, local residents within settlements affected by the BTC, SCP and Koroglu Dam theoretically fall within the sourcing radius for all three projects. This excludes settlements to the east of the SCP, as these fall outside of the BTC sourcing area for unskilled labour. However, Cayagzi is the only settlement that is impacted by all three developments and which falls within the BTC priority area for unskilled labour[1]. Although this settlement thus stands to benefit from cumulative employment opportunities, Cayagzi is due to be resettled outside of this priority area. However, delayed resettlement could result in residents from this settlement securing employment with BTC and SCP projects. Similarly, other dam-affected settlements, which fall within the priority area for semi-skilled and skilled labour (ie Cayagzi, Altas, Balikcilar and Olcek) will also potentially be relocated outside of this 'sourcing radius'.

There are a number of settlements that fall within the expected priority areas for semi-skilled and skilled labour for all three projects (ie intersected districts and provinces) and will therefore potentially benefit from cumulative employment within the broader Project area. Cumulative opportunities for semi-skilled and skilled labour as well as provision of local goods and services are also likely to be experienced on the district and provincial level.

16.5.5 The BTC Pipeline, BTC Marine Terminal and other developments within the vicinity of the proposed terminal

16.5.5.1 Details of the proposed developments

Proposed future developments within a 10km radius of the proposed BTC Marine Terminal are shown on Figure 16.4. Briefly, each development comprises the following:

- **Sugozu Power Plant:** The Sugozu Power Plant is a 1,210 MW low sulphur imported coal fired power plant. Construction of the plant began in November 2000 and is expected to last for approximately three years. The commissioning of the plant is currently planned for November/December 2003. Key facilities include a 600 m jetty for the import of coal from vessels. The jetty is near completion. During the operational phase, the passage of vessels, excluding the tankers, will be prohibited with an exclusion zone of 0.6km^2 (60ha). The construction of the on-shore facilities required the expropriation of approximately 728ha of agricultural land pertaining to Sugozu.

  During the construction phase, a maximum of 4,500 to 5,000 people will be employed, fifty percent of which are from Adana province, and of this, 150 employees are from the surrounding settlements. Non-local employees live in a dormitory near the construction site (Yumurtalik Municipality, 2002). During operation, 250 personnel will be employed. Most of the materials required for construction will be sourced from Adana province. Water demand during the construction phase will be met from existing surface water resources, and from the sea during operation.

[1] The priority areas for sourcing of unskilled labour for BTC pipeline construction and operation is defined as follows.
- Settlements with land that is intersected by the pipeline.
- Settlements that have occupied residences within 500m of the pipeline route
- Settlements within 5km of a main construction camp.
- Settlements within 1km of a construction site (accessible by foot during the working day).
- Settlements that will experience a substantial increase in traffic loads.

- **Sanko Petrochemical Plant:** The proposed industrial complex for petrochemical products will be constructed by SANKO Petrochemical Products Ind. Trade Inc. The plant is located approximately 4.8km west of the proposed BTC Marine Terminal. Although start of construction was initially planned for 1999, this has not yet been realised. The plant will produce raw material for plastics namely, ethylene, propylene, polypropylene, polyethylene granular. Key facilities include a 900m jetty for the transportation of the raw materials produced. During operation of the jetty, an exclusion zone for the safe operation of jetty activities is expected to be enforced. The total extent of this exclusion zone is unknown, although it will cover a minimum area of 1km^2 (100ha).

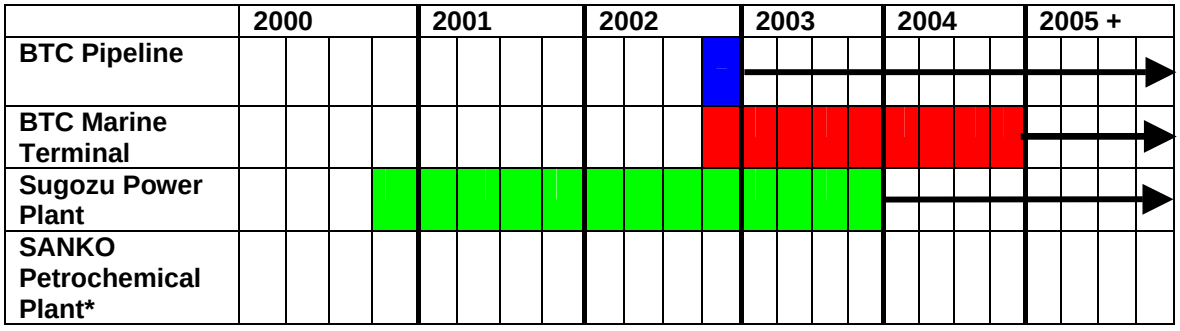
  The total area of land required for the plant is 94ha. This requires the expropriation of 50ha of agricultural land, although it was reported in the EIA to be of poor quality. Residents from Golovasi were among those affected by this expropriation.

  No construction camp is anticipated. All workers are to reside within nearby residential areas (eg Yumurtalik district centre or surrounding settlements). A total of 350 workers will be required for the construction phase and 650-700 workers for the operational phase. Employees will be sourced from settlements most affected by the Project. Thus, residents of Yumurtalik district centre and Golovasi will be prioritised.

  An access road off the Yumurtalik-Ceyhan main asphalt road will be constructed to the site. The length of the road will be approximately 8km. Approximately 34kV of electricity will be generated by the site for its own use. Wastewater treatment plants will also be established for the operational phase. Collection of solid wastes is to be carried out by Yumurtalik Municipality.

The construction and operational schedules for these developments, relative to the BTC Project, are illustrated in Table 16.4.

Table 16.4 Construction and Operational Schedules for Sugozu Power Plant, Sanko Petrochemical Plant and BTC Project



* The construction schedule for the Sanko Petrochemical Plant is currently on hold, reportedly for financial reasons. The EIA Report has however, been approved by the Ministry of Environment.

** Arrows indicate project operation

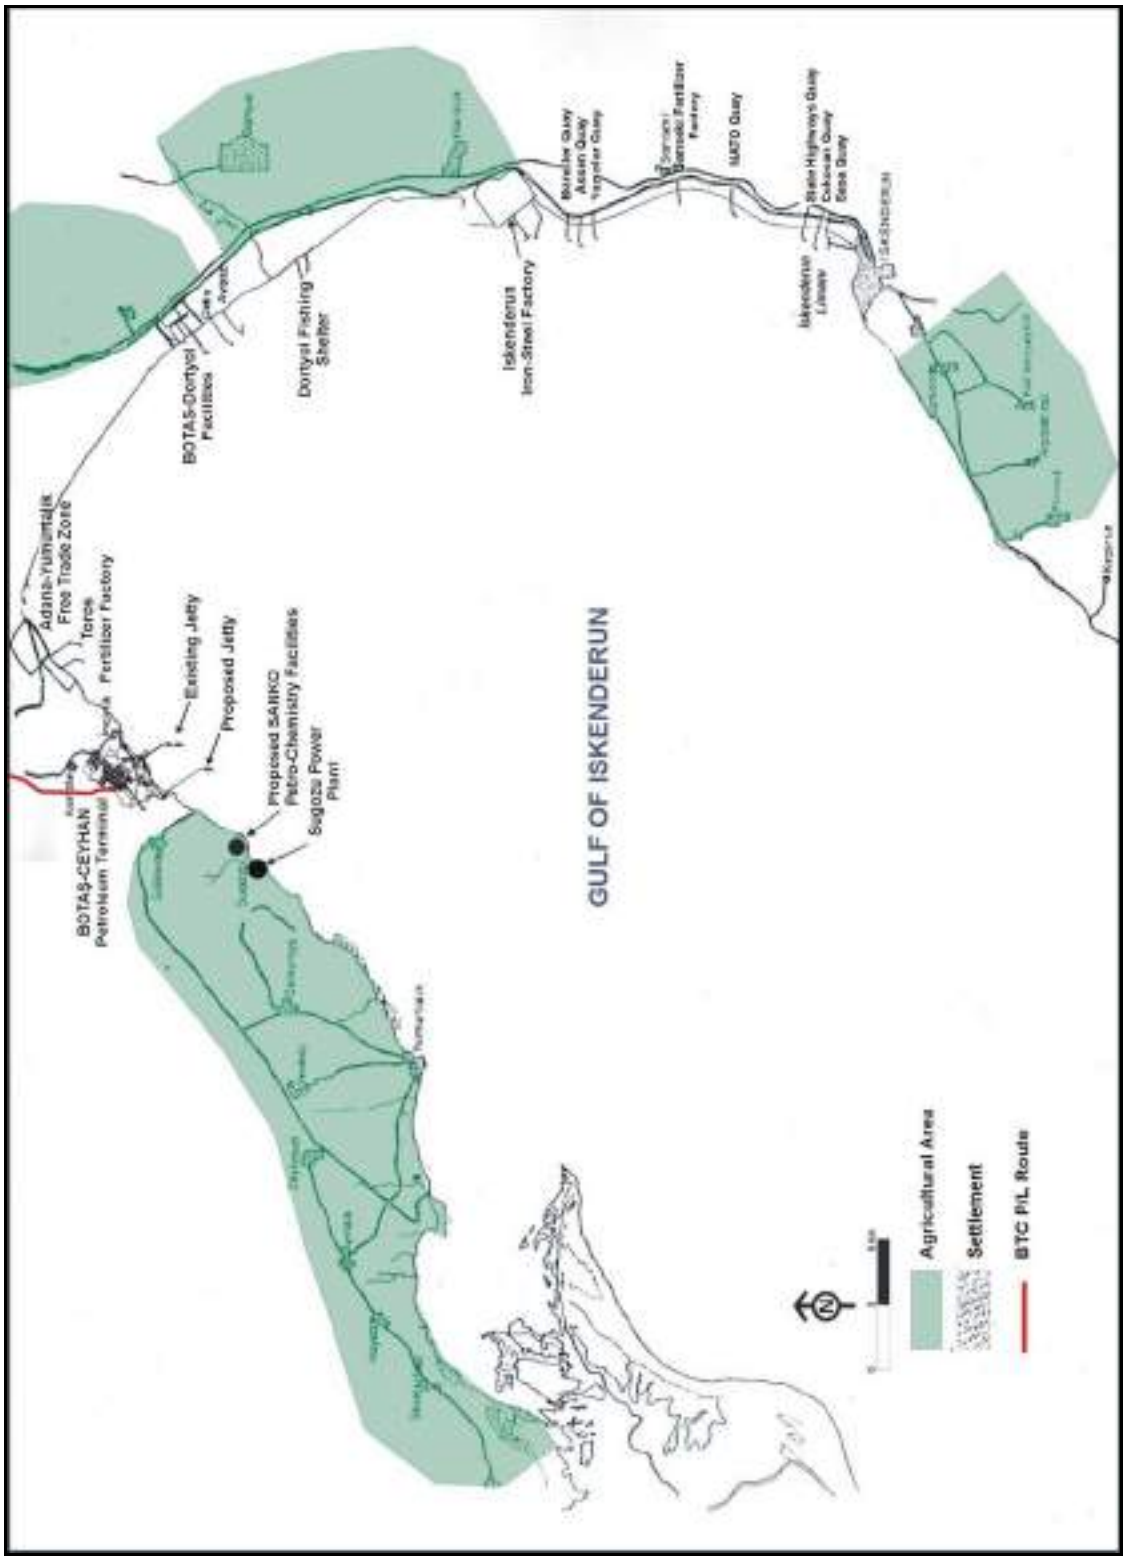


Figure 16.4 Proposed Future Developments Within the Marine Terminal Area

Based on the spatial criteria described in Table 16.1 (with the exception of marine ecology for which a much wider spatial criterion has been used) and project schedules identified above, a number of environmental and socio-economic cumulative impacts are expected. These are discussed in the following sections.

16.5.5.2 Cumulative environmental impacts

Air quality

Emissions of potential concern, from a cumulative impacts perspective, will primarily comprise NO_x and VOCs. Air quality dispersion modelling was undertaken and has considered the potential impacts of all combined sources of emission (see Section 12 and Appendix B2).

The Sugozu Power Plant, which is currently under construction, will be the largest NO_x emitter (93.8%) in the Project area (ie northern end of Gulf of Iskenderun). In addition, local traffic will contribute to total NO_x emissions. The Sanko development is a likely future emitter of NO_x. The BTC Marine Terminal (EGF flare and vessel emissions) will produce approximately 78 te yr NO_x which will constitute less than 0.5% of the total NO_x emissions in the Project area. As such, the scope for cumulative impacts by the addition of the BTC Project is small.

However, if the criteria established in Section 3 for assessing air quality impacts are applied, the worst case annual average ground level NO_x concentration is predicted to be less than 50% of the equivalent EU NO_x standard (annual average concentrations range from 6.9 to 18μg^{-3} against the EU Standard of 40μg^{-3}). As such, the combined emissions from all sources constitute a Minor (<70% of Environmental Assessment Level or 'EAL') impact to long-term ambient air quality.

The existing BOTAŞ crude oil loading facility is the largest VOC emitter in the area comprising 88% of total VOC emissions. In addition, local traffic will also be a source of VOCs along with the future development of the Sanko project. The Sugozu Power Plant can also be expected to emit significant quantities through incomplete combustion. The proposed BTC Marine Terminal will emit a total of 240 tonnes of VOC per year, which constitutes approximately 7% of the total VOC emissions anticipated in the area.

Since the predicted 95th percentile hourly groundlevel concentration of VOC emissions currently exceeds the Turkish Standard on occasions (up to 824μg^{-3} against the Turkish Standard of 140μg^{-3}), the predicted cumulative emissions of VOC constitute a Major environmental impact. It should be noted, however, that the contributions from the proposed BTC Marine Terminal itself constituting a Minor impact only, comprising less than 25% of the EAL.

VOCs and NO_x combine to form tropospheric ozone under certain conditions. While this is a potential problem in the Bay of Iskenderun area, emissions of NO_x and VOCs from the BTC Marine Terminal are dwarfed by those from other local sources; the BTC Marine Terminal will not, therefore, make a substantial contribution to this potential impact to air quality. If there is a cumulative impact to trophospheric ozone, the significant contributors to such a problem will be the existing BOTAŞ facility and the Sugozu Power Plant.

A strategy has already been adopted by the BTC Marine Terminal to minimise VOC emissions and the flare is predicted to meet the NO_x standards. As a result, while the BTC Marine Terminal will make a small incremental contribution to cumulative air quality impacts, that contribution has already been mitigated as far as is reasonably practical.

Construction traffic

At this stage in the planning of the BTC Project, it is not possible to state which roads will be used by construction traffic and hence it is not possible to assess whether there will be any interaction with construction traffic associated with the Sugozu Power Plant. However it is reasonable to assume that the majority of heavy goods vehicle movements (the main source of potential traffic impacts) for the power plant will have diminished substantially by the time that the BTC Marine Terminal construction commences.

The Contractor for the BTC Pipeline Project will be required to formulate a Traffic Management Plan and this will take account of any interaction with the Sugozu Power Plant construction traffic.

Water Resources, Construction Aggregates and Solid Waste

Resource use and waste management all raise potential cumulative impact issues given the ongoing and likely future scale of development on the Gulf of Iskenderun. Much the same issues will result as described in section 16.5.3.2 above, and will require much the same management responses.

Shipping and navigation

The BTC Marine Terminal will be one of several that will add to the degree of marine transport movements into and out of the Gulf of Iskenderun. Lack of data on both the baseline and the other developments precludes any meaningful consideration or quantification of cumulative impacts (including added collision risk) of these developments. However, BOTAŞ has committed to a shipping risk study and this will also consider new proposed developments in the Gulf (see also Oil Spill Risk below).

Oil Spill Risk

Loading of oil at the BTC Marine Terminal Jetty and its transport on tankers out of the Gulf of Iskenderun will add to an existing level of risk in this area of the north-eastern Mediterranean. The incremental level of risk increase will be a function of increased marine traffic and increased inventory of oil. The BTC Project is addressing this risk in two ways.

- As part of the BTC Project Oil Spill Response Plan (see Appendix C6) a tier one response capability will be maintained at the BTC Marine Terminal. The equipment would be able to deal with a typical loading spill (the most likely spill event, see Section 14). It would also be available to make up a local tier two response in the event of a third party spill. The provisions of the OSRP largely mitigate the incremental increase in risk of oil spill due to the BTC Project.

- A marine traffic study will be undertaken to gain an understanding of vessel movement in and out of the Gulf of Iskenderun, and whether there are any currently unknown navigational risks (which in turn could increase spill risk).

Marine Ecology

The Gulf of Iskenderun in general is seeing an increased level of industrialisation around its coastline, of which the BTC Marine Terminal is one development. Each development can incrementally increase impacts to marine ecology in general through habitat loss and degradation and impacts to water and sediment quality.

Although the most important coastal area of nature conservation value (Yumurtalik Lagoons Nature Reserve) is protected, there are still valuable areas outside this, including beaches used by marine turtles to lay eggs. The BTC Marine Terminal will contribute to these problems in only the most minor of ways since, for example:

- it will not occupy sandy beach habitat;
- it has no substantial wastewater discharge to the marine environment;
- the area of seabed habitat affected has no intrinsic conservation value;
- the causeway and jetty structures will provide new habitat substrate and shelter for fish and other organisms.

However, the project will have provision for an Environmental Investment Programme and opportunities, such as marine turtle conservation, will be sought to participate in and contribute to future programmes in the Gulf.

Other environmental issues

The new pipeline will add to the existing landscape and visual impacts of the inadequately reinstated RoW of the NGP for those sections where the two pipelines share a common alignment. Similarly, the construction of the SCP and the BTC Pipeline could potentially give rise to Major, localised short-term cumulative impacts. However, the commitment to rehabilitate and reinstate sections of the NGP will ensure that the cumulative impacts in the longer-term are likely to be beneficial to the visual amenity of the landscapes through which the two pipelines pass. Similarly, close coordination and cooperation between the BTC and SCP project teams would provide a means of ensuring that cumulative construction related impacts are minimised and that the longer term cumulative landscape and visual impacts are Minor. The existing industrial landscape within which the BTC Marine Terminal is to be developed will accommodate the new facility to a far greater degree than would have been the case if the Marine Terminal were to have been located within a largely undisturbed landscape. The cumulative implications of the additional structures form the basis of the impact assessment presented in Section 12.

There are several areas where the combined noise from the parallel construction of the BTC and SCP projects may give rise to localised, short-term Major cumulative impacts. In particular, the settlement of Turkgozu (KP1) is located approximately 500 m east of the BTC Pipeline and 250 m east of the SCP pipeline. The settlements of Armutveren and Kumlukoz are located approximately 500m to the east of the BTC Pipeline and within 1.5km of the SCP pipeline. Jointly implemented mitigation measures will include staggered construction and additional mitigation in the form of acoustic screens and, as a consequence, cumulative impacts are predicted to be minor.

16.5.5.3 Cumulative social impacts

Construction camps

Construction camps and the associated workforce have the potential to result in a number of impacts, both positive and negative, for local residents. However, based on the potential areas of impact of construction camps[2], any cumulative impacts associated with the identified projects

[2] The potential areas of impact of construction camps are considered to be as follows: 1) settlements that fall within a 5km radius of the construction camps and are therefore accessible on foot from the camp; and 2) settlements located within driving distance (assumed to be within a one hour car journey) of the construction camps.

pertain to settlements within driving distance of the construction camps for each of these developments. This is due to the fact that no settlements fall within a 5km radius (ie walking distance) of the BTC construction camp and one or more of the other identified developments.

The larger towns/district centres which have the potential to attract construction staff for purchasing of supplies, entertainment etc include: Ceyhan, Yumurtalik and Adana. Settlements such as Sahil Sitesi and Incirli could also benefit from increased expenditure due to the popularity they already enjoy as tourist destinations. In terms of the specific projects under assessment, this cumulative benefit will occur over an approximate duration of 15 months (the period during which the construction of the BTC Project and Sugozu Power Plant overlap) resulting in an extended duration of employment for construction workers in the area. Given that these identified settlements are either district centres or existing tourist destinations, it is anticipated that they will be able to effectively absorb any supply or service demands placed on it by the visiting workforce.

Land ownership and use

The Iskenderun Gulf area has been identified as an industrial zone, evident in the increasing number of existing and planned developments within a 10km radius of the proposed BTC Marine Terminal, as well as elsewhere along the Iskenderun coast (see Figure 16.4). On completion of three of the planned developments (Sugozu Power Plant, Sanko Holdings and the BTC Terminal), there will be a total of six jetties within a distance of 15km. Each of these jetties will have exclusion zones within which fishing activities and the transit of local vessels will be prohibited. This will result in an overall decrease in the size of the fishing grounds available to local fishermen.

Although the Iskenderun Gulf has experienced a decrease in fish stock since the early 1980s, with current fish stock reported to be low[3], households still depend on fishing as a main source of income. This is due, in part, to limited alternative forms of livelihood (few opportunities for wage labour and low land availability) and the role fishing plays as a 'way of life'. Thus, any further restriction on access to fishing grounds is expected to further undermine the viability of fishing as a source of livelihood. This, in turn, will have implications for people's ability to maintain their existing levels of livelihood.

Although increased opportunities for wage labour is a definite benefit of industrialisation, local residents do not necessarily have the skills needed to gain employment. The concern therefore remains that affected residents will not be able to replace their lost sources of livelihood. Furthermore, opportunities for wage labour are also likely to benefit the younger generation (who are more likely to be able to make the transition from one form of livelihood to another) but does not address the loss of fishing as a way of life, or benefit people in middle age and over.

Industrialisation will also require further expropriation of land for on-shore developments. Golovasi and Sugozu, both within a 10km radius of the BTC Marine Terminal, have had land expropriated for the Sanko Petrol Chemical Plant and Sugozu Power Plant respectively. Although compensation will have been provided, concerns regarding the ability of affected households to secure a long-term livelihood remain. This is due to limited alternative forms of subsistence livelihood and the uneven distribution of land characterising the broad Project area, which could be accentuated by land expropriation.

[3] According to the local authorities and fishermen, the Iskenderun Gulf has a decrease in fish stock, due to increase environmental pollution, trawling and over fishing.

By way of response, the Project has committed to assisting in the acquisition of appropriate transferable skills within neighbouring settlements, thereby maximising the potential for securing employment within the wider Project area. A procedure for compensation will also be developed and targeted at registered fishermen who incur a loss of livelihood as a result of the construction and operation of the BTC Marine Terminal. In keeping with World Bank requirements, the compensation process will include procedures for internal and external monitoring, as well as measures for addressing any feedback received. Furthermore, the Project will implement a Community Investment Programme and Social Investment Strategy in order to bring sustainable benefits to settlements most affected by construction and operational activities. However, such efforts will fall short of addressing the cumulative impacts of industrialisation in the Iskenderun Gulf areas, the overall development and associated planning is considered to be the responsibility of the Turkish Government and relevant provincial/district authorities. The impacts of cumulative industrialisation will however be mitigated, in part, by increased opportunities for wage labour in the Iskenderun Gulf area.

Employment and provision of goods and services

Based on an assumed 'sourcing radius' of 10km for unskilled workers, local residents neighbouring the four identified developments[4] theoretically fall within the sourcing radius for all four projects. However, the cumulative impacts of direct employment of unskilled workers is likely to be restricted by the BTC policy on employment of project affected residents[5]. As a result, those settlements that fall within the 10km 'sourcing radius' but who are not included in the BTC priority areas, will not be given preference as unskilled workers on the BTC Project. However, these settlements do fall within the BTC priority areas for semi-skilled workers (ie within Yumurtalik and Ceyhan district and Adana province) and for skilled workers (ie within Adana province and Turkey) and will therefore potentially benefit from cumulative employment within the broader Project area.

Residents from Golovasi, by virtue of their status as project affected residents for both BTC and Sanko Petrochemical Plant, stand to benefit from preferential employment for both projects. Due to the sequential timing of the construction phases, these employment benefits will be extended over a period of almost four years.

Other indirect cumulative benefits include increased cash flow into the local economies (and associated knock-on effects) and opportunities for the provision of goods and services. In addition, workers who have experience on more than one project will be more attractive to future employers, and opportunities for training and learning new skills for those employed will be extended. These benefits, together, will have a combined positive impact on the health of the local economy.

Infrastructure and services

The EIAs undertaken for each of the four projects reported that no significant impacts to infrastructure and services will incur as a direct result of the respective projects. Where local infrastructure and services are not sufficient to meet additional demands, all the projects have committed to being self-sufficient, both during construction and operation. This will be controlled, in part, by the relevant permitting requirements that apply to projects of this scale.

4 The BTC Pipeline (most southerly portion) and BTC Marine Terminal are counted as two separate projects for the purposes of the cumulative assessment.

5 Priority to be given to residents of directly affected settlements where these are defined as follows:

- settlements of Golovasi / Sahil Sitesi, Karatepe and Incirli.
- settlements that experience a substantial increase in traffic loads.
- settlements within a 5km radius of the construction camp (in the case that workers are not housed in an urban centre or within BOTAŞ property).

A policy of restoring or compensating for any damage incurred to local infrastructure is also expected to be enforced for all four projects.

However, with increased industrialisation in the Iskenderun Gulf area, a gradual in-flow of people is expected as job opportunities increase. Any impacts that this causes will depend on whether the broader Project area is able to provide the necessary infrastructure, services and resources needed for the new population totals. An overview of conditions in the vicinity of the four identified projects indicate that the existing services and resources are not sufficient to meet the needs of either the current or additional populations. In the absence of mitigation, this could potentially impact on the levels of livelihood of existing residents.

Although the BTC Project have committed to measures aimed at discouraging in-migration to settlements neighbouring the BTC Project (eg through wide publication of their employment strategy), this will not curtail a general influx of job-seekers to the broader Project area.

Safety of residents

Based on the current road network within the broad Project area, the Sugozu Power Plant, Sanko Petrol Chemical Plant and the BTC Terminal will all use the same access roads. These are the Yumurtalik-Ceyhan main asphalt road and the state road connecting Ceyhan and Adana district centres. Common use of local roads is currently unknown. However, any potential cumulative impacts associated with road use (eg safety risks and traffic congestion) will be mitigated by the sequential timing of the construction phases. Although traffic loads will be staggered, these roads (and neighbouring settlements) will be subjected to a longer duration of traffic disturbance. The significance of this needs to be assessed within the context of on-going industrialisation in the Iskenderun Gulf area. Local and main roads will thus be subjected to increasing construction and operational traffic from numerous developments within the broad Project area.

The community relations team for the BTC Project will ensure that settlements subject to increased traffic loads as a result of the BTC Project will receive safety awareness training and community briefings regarding construction activities. These briefings could raise sufficient traffic and safety awareness among settlements along these shared access roads. In addition, the BTC Project will compile and implement a TMP that addresses, among other issues, the safety risks associated with the construction traffic for the BTC Project.

Community relations

A deterioration in relations between the settlements and neighbouring projects, as a result of cumulative impacts associated with all four projects, could potentially occur. This would most likely be a result of the cumulative loss of access to fishing grounds, in the absence of job procurement or alternative sources of subsistence livelihood.

Each project has settlements within their area of impact that reported a reliance on either fishing or agriculture as a source of livelihood. The community relations teams for the BTC Project will monitor the success of mitigation measures designed to address any loss specific to their development. Similar commitments from the other developments would be beneficial. Following completion of the additional fisheries study currently underway, compensation measures may be awarded to affected fishermen. Procedures for internal and external monitoring associated with compensation related impacts will be implemented.

Although the cumulative impacts of industrialisation are not the responsibility of the BTC Project, it is strongly advised that, in the interests of on-going community relations, attitudes to

cumulative development will be included in the monitoring of community attitudes undertaken by the BTC community relations teams. Where negative attitudes are noted, mitigation measures that focus on cumulative impacts will be considered. This includes for example, joint partnering initiatives with government, other companies and civil society in the Iskenderun Gulf area in order to address the cumulative impacts of industrialisation.

16.6 SUMMARY OF CUMULATIVE IMPACTS

The assessment of cumulative impacts has assessed the potential for the combined effects of existing projects, the proposed project and anticipated projects to impact at the global, regional, national and local level.

At the global level, the Project's contribution to greenhouse gas emissions will occur primarily during operation, when the BTC Project in Turkey would contribute approximately 0.0016% to global anthropogenic emissions of greenhouse gases. At a regional level, the BTC Project, together with the wider ACG and South Caucasus Project, will provide significant developmental benefits to the economies of the region. A proportion of these benefits would accrue to Turkey.

At the national and local level, cumulative impacts are likely due to the parallel development of the BTC, the SCP and other planned infrastructure projects, including the Koroglu Dam and the proposed Sugozu Power plant. At a national level, considerable socio-economic benefit is expected from the inward investment and potential revenues associated with these developments, whilst the application of Turkish environmental and planning control legislation are viewed as providing appropriate mechanisms for mitigating and monitoring any potential negative impacts that might accrue.

At the local (route) level, there exists significant potential for cumulative impacts to arise at specific locations where BTC construction activities are scheduled to take place in proximity to those associated with the SCP. Similarly there are a number of potential cumulative impacts with other development around the Gulf of Iskenderun. To some extent these impacts will be mitigated by the measures already described in this report. Some cumulative impacts will require additional measures. These are summarised in Table 16.5 below.

Table 16.5 Summary of main cumulative impacts and their management

IMPACT	MANAGEMENT
BTC and SCP in combination	
Ecology of Posof Forest	Consideration should be given to the timing and feasibility of constructing either in different years or to stagger work (eg one spread moves south to north and the other north to south).
Groundwater abstraction (if it is required from the same aquifer)	Consideration to be given to ensure that the aquifer can sustainably supply both projects' needs without impacting other users.
Construction aggregate resources and quarries	Consider the requirements and how these will be met from existing and, potentially, from new sources in a way that does not impact other users.
Solid waste disposal	Review volumes and types of wastes arising and where they will be disposed in relation to SCP. This will allow possible existing capacity problems to be identified at an early stage and alternatives to be examined.
Employment and provision of goods and services	Respective employment strategies should be consistent, where appropriate, and feasible. Similar strategies will assist in preventing resentment due to perceived or actual inequalities in the respective strategies.
Infrastructure and services	To review respective requirements (with regulatory input). This will allow possible existing capacity problems to be identified at an early stage and alternatives to be examined.
Safety of residents	Recognition for raising awareness with regard to the two projects among affected settlements and minimising associated risks.
Community relations	Identify aspects of the projects most likely to put strain on relations with local residents. Procedures for managing these aspects to be agreed upon. Likely areas include expectations regarding employment, the compensation process, construction activities and associated nuisance factors. Establish a procedure whereby any grievances or suggestions for improvements submitted by local residents are forwarded to the respective project representatives and dealt with accordingly.
Note: BOTAS will be responsible for the construction management of both the BTC and SCP projects in Turkey. Consequently, cooperation between the two project departments will facilitate project understanding and aid in the mitigation of the above potential cumulative impacts.	
BTC, SCP and Koroglu Dam	
Land ownership and use	Develop an approach for dealing with cumulative impacts relating to the settlement of Cayagzi. In particular, coordinated community relations activities are recommended, as well as strict enforcement and monitoring of measures to address nuisance factors such as traffic, noise, dust, unplanned disruptions etc). Any grievances or suggestions for improvements submitted by local residents are forwarded to the respective project representatives and dealt with accordingly.

IMPACT	MANAGEMENT
Employment and provision of goods and services	Cognisance of the employment of local residents affected by the three projects.
BTC Terminal, Sugozu Power Plant and other major local construction programmes	
Water use, aggregate sourcing and waste disposal	Investigate sustainability of resource with respect to other projects.
Construction traffic	Development of the BTC Traffic Management Plan will entail recognition of other construction programmes in the area, in the course of which potential transport problems jointly raised by the projects (eg road congestion, road improvement needs) should be assessed and acted on.
Operational air quality	Possible cumulative air quality problems include VOC breach of local air quality and potential formation of ground level ozone. While the BTC Marine Terminal will make minor contributions to both of the above, the Project will carry out an air quality monitoring programme. Discuss the possibility of exchanging information with other monitoring programmes so that, in conjunction with the regulators, the extent of any cumulative problems can be properly understood as a precursor to taking some form of appropriate management action.
Marine ecology in the Gulf of Iskenderun – increment by increment degradation	BTC will contribute to this cumulative impact in only a minor way. In the absence of any collaborative effort involving the authorities and other operators, BTC Co will establish the most productive initiatives for nature conservation in the Gulf of Iskenderun in the context of the proposed Environmental Investment Programme for the project.
Employment	Maximise the employment and skills enhancement of local residents affected by all projects, including fishermen impacted upon by decreased access to fishing grounds.
Infrastructure and services	As above
Safety of residents	As above
Community relations	Recognise the cumulative development effects on relations with local residents within Project procedures for managing these aspects. Likely areas include decreased access to fishing grounds, expectations regarding employment, construction activities and associated nuisance factors.

17 MANAGEMENT AND IMPLEMENTATION

17.1 INTRODUCTION

This EIA has identified a number of measures to minimise and mitigate the potential environmental and social impacts that may arise due to the various project activities. There are two broad categories of mitigation[1] measures that will apply to the BTC Project:

- generic good practice measures, which will ensure that the facilities are built and operated to standards of international best practice;

- specific measures, which will ensure that, predicted impacts are mitigated to acceptable levels.

The effective implementation and maintenance of mitigation measures underpin the findings, recommendations and conclusions of this EIA and represents a key condition of the EIA approval process.

Whilst this EIA document reports the assessment, analysis, findings and recommendations of the EIA process up to the point of disclosure, the integration of environmental consideration into the implementation phases of the development will be an ongoing and dynamic management activity. In this Section, the means by which integrated environmental and social management is to be achieved are described.

17.1.1 Environmental and social management plans

A key vehicle for the delivery of environmental management scrutiny and control is the suite of management plans developed by the EIA team and attached to this main EIA Report as Appendix C. The Management and Monitoring Plans (MMPs) comprise the following:

- an Environmental Management and Monitoring Plan (EMMP);
- a Reinstatement Plan (RP);
- a Waste Management Plan (WMP);
- a Pollution Prevention Plan (PPP);
- a Traffic Management Plan (TMP);
- an Oil Spill Response Plan (OSRP);
- a Cultural Heritage Management Plan (CHMP);
- an Aggregates Management Plan (AMP);
- a Social Management and Monitoring Plan (SMMP).

The management plans represent the technical basis for the development and maintenance of key environmental management systems and procedures during construction and operation of the scheme and will evolve and adapt as the implementation of the pipeline and its associated facilities is progressed.

[1] In this context, mitigation refers to both measures to prevent or minimise negative impacts, and also measures to optimise potential benefits of the Project.

The management plans have been prepared for those who will be responsible and accountable for the implementation and maintenance of the mitigation measures identified by the EIA process. As the Project Proponent, BTC Co has provided a commitment to comply with the requirements of the EIA; as such the plans will provide important information to a range of individuals from boardroom down to site personnel and from members of the proponent organisations through to Construction Contractors and Sub-contractors.

Those accountable for achieving the objectives of the plans should ensure that the required actions for both implementation and monitoring are integrated into wider management processes, thereby ensuring that environmental and social impacts are considered in all relevant project decisions and activities.

As public documents, the suite of management plans also provide a point of reference for regulators, communities and other interested parties who would like to understand the specific activities to be undertaken by the Project as well as the allocation of responsibilities between the different parties to the Project. These management plans will also provide a basis for assessing the environmental and social performance of the Project through external monitoring and will facilitate public scrutiny of those identified as holding responsibility for the actions of the Project.

The management plans are aimed, therefore, at:

- ensuring that the management actions and mitigation measures described in the EIA are successfully carried out;
- establishing the requirements for monitoring the effectiveness of measures implemented; and
- providing procedures for reviewing and amending mitigation measures as required to reach established objectives and targets.

In addition to the effective management of the Project activities, BTC Co are also committed to providing direct benefits to affected communities and environment through focused investment programmes. Section 17.4 outlines BTC Co's environmental and social investment programmes.

Sections 17.2 to 17.3 provide a brief overview of the way in which environmental management of the Project will be carried out.

17.2 PROJECT MANAGEMENT SYSTEMS

17.2.1 BOTAŞ Quality Management System

The BOTAŞ Quality Management System provides the structure for the overall quality management of the BTC Project. Environmental and social management is an integral part of the process of ensuring that the protection of the environment and communities are given a high priority throughout the Project.

BOTAŞ has developed an Environmental Management System, in accordance with the international standard ISO 14001. This will be applied to the BTC Project.

The aim of the EMS will be to ensure that environmental requirements are identified, planned, achieved, maintained and documented and, where appropriate, improved. Specific focus will be

provided through the Management and Monitoring Plans and supporting plans in their current form; these documents are aimed primarily at the construction and commissioning phases of the Project. However, the plans and procedures will be developed for application during the operational phase and, ultimately, through to the decommissioning of the pipeline.

17.2.2 Overview

BOTAŞ is committed to the full integration of environmental and social management requirements within the overall Project Management System to be applied to the construction, operation and eventual decommissioning of the BTC Pipeline and its associated facilities. This commitment is reflected by the close integration of environmental considerations into the planning and design development of the Project to date.

The management and planning of environmental requirements of the BTC Project will be effected through the following:

- The BOTAŞ Quality Management System;
- Management and Monitoring Plans (MMPs) including Project-wide Environmental Management and Monitoring Plan (EMMP) and Supporting Plans, and the Social Management and Monitoring Plan (SMMP) and Supporting Plans;
- Contractor Environmental and Social Management Plans and Procedures; and
- Operational Plans and Procedures including, for example, the Emergency Response Plan and Oil Spill Response Plan.

The relationship between these different components is illustrated graphically in Figure 17.1 and a brief description of the various components is provided in Sections 17.2.3 to 17.2.6 below. An overview of some of the key features associated with the implementation of the various plans is contained in Section 17.3.

The Project–wide EMMP and other supporting management plans for the construction phase are contained in Appendices C1 to C7 and C10. The Project-wide SMMP and other supporting management plans for the construction phase are contained in Appendix C8. Environmental and social management is a process that will continue to be refined as the Project develops through detailed design to construction, commissioning, operation and decommissioning. Consequently, these plans will be ‘living documents’ that will be developed and revised in parallel with developing project design and implementation.

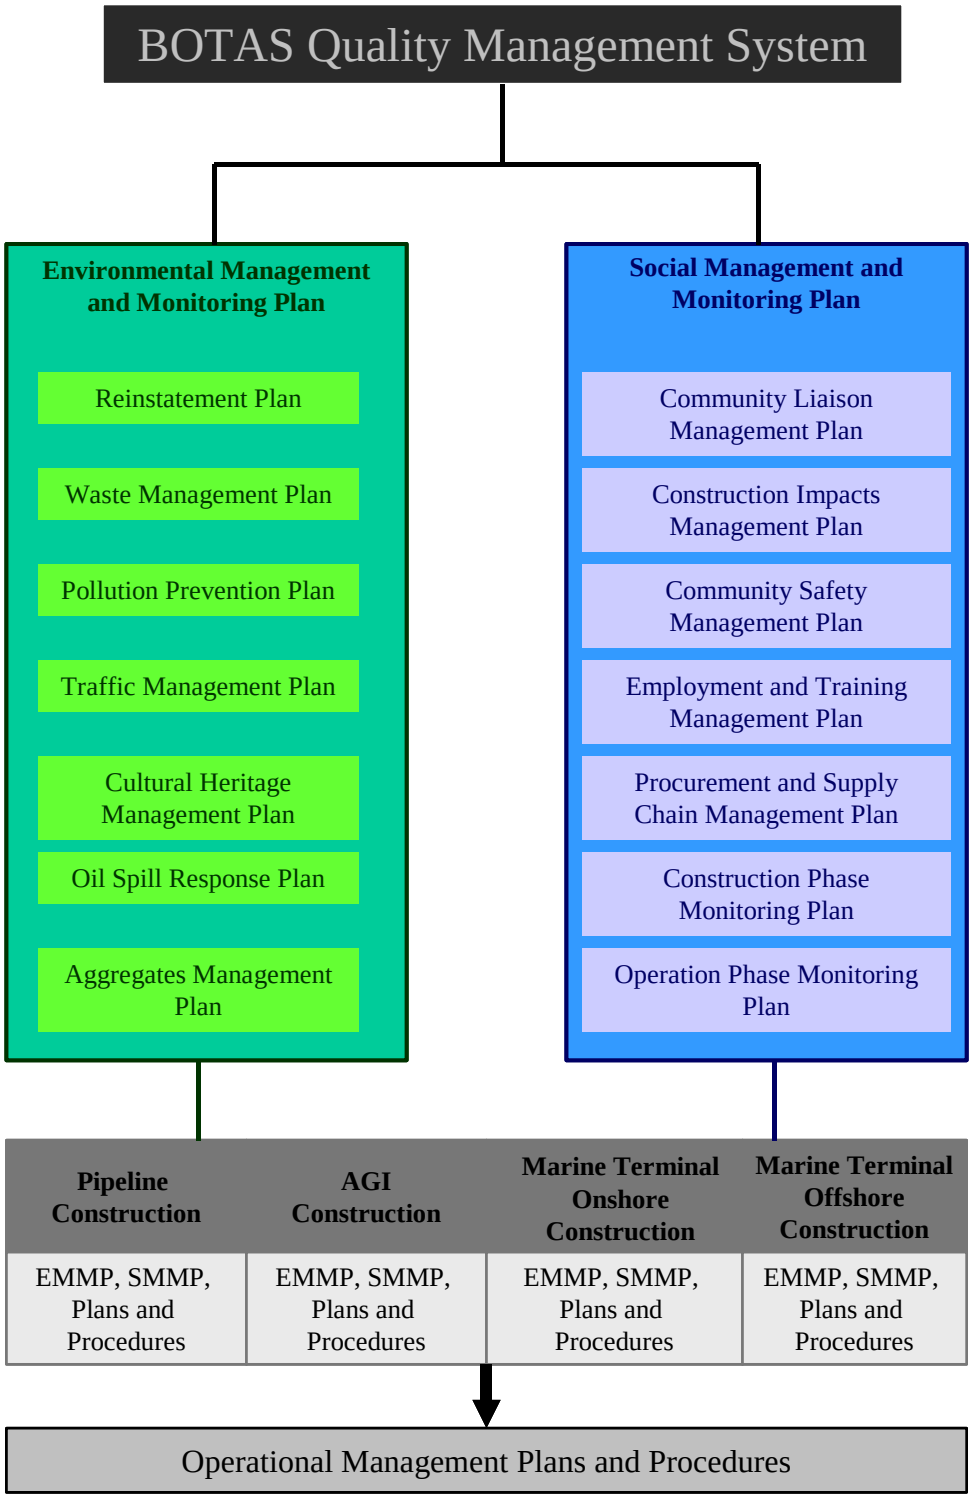

Figure 17.1 Overview of BOTAŞ Quality Management System

17.2.3 Environmental Management and Monitoring Plan

The Environmental Management and Monitoring Plan (EMMP) is an overview document that guides the environmental management and monitoring of all aspects of the BTC Project. This document addresses project wide issues and requirements that shall be adhered to by BOTAŞ and its Contractors in all aspects of the BTC Project. In addition, this document acts as a guide to the supporting suite of management plans and other documentation that together constitute the environmental management framework for the Project. At this stage of the Project the EMMP is primarily aimed at the construction and commissioning phases of the Project. However this document will be reviewed and revised as the Project develops through to the operational phase.

17.2.4 Supporting environmental management plans

This section provides a brief summary of the scope of the various Environmental Management Plans that support and complement the EMMP.

17.2.4.1 Reinstatement Plan

This plan specifies the minimum technical requirements for reinstatement and restoration of areas affected by construction activities excluding areas of permanent land take. The primary aim of the Reinstatement Plan (RP) is that all such areas shall be returned to their pre-construction state. The RP is applicable to the stabilisation and restoration of terrain before, during and after construction of the pipeline Right of Way (RoW), access roads/tracks, Above Ground Installations (AGIs), staging areas and any additional areas utilised during construction of the various components of the BTC Project.

17.2.4.2 Waste Management Plan

The project-wide Waste Management Plan (WMP) identifies wastes which are likely to be generated during the construction of the BTC Project and documents the 'cradle to grave' waste management practices to be employed for their collection, storage, treatment and/or disposal.

The WMP covers wastes generated by construction and related activities including the following sources:

- construction and commissioning of all facilities;
- accommodation both temporary and permanent (used during construction);
- infrastructure such as transport and airstrips / helicopter pads.

The WMP describes how waste will be managed and how the Project will:

- minimise the potential to cause harm to human health and the environment;
- achieve and maintain compliance with Turkish regulations and BOTAŞ environmental goals; and
- reduce operational costs and reduce any potential liabilities that may arise from waste handling operations.

17.2.4.3 Pollution Prevention Plan

The Pollution Prevention Plan (PPP) documents the project-wide measures that are required to avoid and minimise pollution during project activities and to respond to any pollution incidents that occur. Specifically, the PPP addresses the following areas:

- fuel storage and handling;
- protection of surface and groundwater;
- preventing marine pollution;
- controlling dust and other emissions to air;
- controlling noise; and
- spill prevention and control.

17.2.4.4 Traffic Management Plan

The Traffic Management Plan (TMP) addresses the measures that will be adopted throughout the BTC Project to minimise traffic related impacts. Specifically, the TMP addresses:

- relevant traffic management policies and standards;
- potential traffic impacts of the Project; and
- appropriate measures and procedures for mitigating the impacts.

17.2.4.5 Oil Spill Response Plan

The Oil Spill Response Plan (OSRP) documents the responsibilities, procedures and methods of response that will be utilised in the event of an oil spill during the operational phase of the Project.

A project-wide oil spill response framework document has been developed by the BTC Co in order to ensure consistency and the efficient use of resources throughout all three countries. The Turkish OSRP will be consistent with the requirements of this framework document. An outline Turkish OSRP is under development at this stage and will continue to be developed by BOTAŞ during the construction phase of the Project in line with the schedule detailed in Section 12 of the framework document.

17.2.4.6 Cultural Heritage Management Plan

The Cultural Heritage Management Plan (CHMP) documents the way in which potential impacts on Turkish archaeological resources will be managed. An Archaeological Management Framework that will apply to the overall BTC Project, including the Azerbaijan and Georgian components of the Project, has been developed by the BTC Co to ensure that archaeological management is treated in a consistent way in all three countries. The Turkish CHMP is intended to be consistent with this overall Framework.

The Turkish CHMP will specifically address the following issues:

- a phased approach to archaeological baseline study and data collection;
- requirements and procedures for undertaking intrusive archaeological investigations;
- specific management strategies for identified archaeological and cultural heritage sites;
- chance find procedures to be adhered to in the event of an archaeological find during construction activities;
- procedures for the reporting of archaeological finds.

The plan will also be implemented according to a protocol agreed between BOTAŞ and the Ministry of Culture, which is aimed at the maximum protection of cultural resources while ensuring the minimum possible delay to the project works.

17.2.4.7 Aggregates Management Plan

The Project-wide Aggregates Management Plan (AMP) identifies the estimated requirements for construction aggregates, outlines the existing capacity in Turkey to provide aggregates for the Project, identifies the potential impacts of aggregate sourcing and recommends appropriate measures to mitigate them.

The Contractor shall use the Project-wide AMP as the basis for preparing a detailed AMP to identify the actual quantity of aggregates needed per Contract, and will include detailed procedures for the management and mitigation of the potential impacts of aggregate extraction and transportation.

17.2.5 Social Management and Monitoring Plan

The Social Management and Monitoring Plan (SMMP), and the supporting framework for the Overview of Land Acquisition Plan, have been developed to achieve the following overarching objectives:

- build positive, non-dependent relationships[1] between the Project and local communities;
- optimise potential benefits brought by the Project; and
- minimise negative impacts caused by the Project.

These objectives have been developed into a set of principles that have guided the development of mitigation measures. These principles are shown in Box 17.1 below**.**

The overall performance and successful implementation of the SMMP will be measured against the objectives and Key Performance Indicators presented in Table 17.1.

Table 17.1 Overall Objectives for the SMMP and Key Performance Indicators

OBJECTIVE	KEY PERFORMANCE INDICATOR
Build positive, non-dependent relationships between the Project and local communities	Number of lost days due to community disturbance
Minimise negative impacts caused by the Project	Compensation paid as a result of project impacts other than pre-construction land compensation
	Injury or loss of life to community members
Optimise potential benefits brought by the Project	Proportion of unskilled, semi-skilled and skilled to be employed from directly affected communities, district, provincial and national levels
	Number of training days per 100 staff in addition to HSE training
	Proportion of goods and services supplied from districts and provinces crossed by the BTC Pipeline

Measurable targets will be set prior to the end of disclosure, for each of the key performance indicators outlined in Table 17.1 above. These will be agreed between the BTC Co., BOTAŞ

1 The project will aim to prevent dependency building up between the settlements and the Project. The Project will not duplicate or replace the legitimate role of existing governance and development structures.

and the Construction Contractor as a formal condition of contract. These targets will be made publicly available and will be monitored throughout the construction period.

Box 17.1 BTC Co. Statement of Social Objectives

The BTC Co. is committed to delivering mutual benefits to potentially affected settlements and to establishing long-term relationships with these settlements, during both the construction and operational phases. We will:

- minimise potential negative social impacts through identification and mitigation, in particular via the environment impact assessment (EIA) process;
- publish regular updates on the environmental and social aspects of the Project, and conduct regular dialogue with interested organisations;
- maintain regular contact with settlements along the pipeline route through a team of CLOs prior to, during and following the construction period;
- compensate for damage to land and property in a legal, transparent and ethical manner that respects the interests of those involved;
- manage expectations on employment opportunities by providing information on the level and duration of employment requirements;
- seek opportunities to increase employment of country nationals, and in particular those in directly affected settlements, subject to availability of appropriate skills;
- establish recruitment procedures that are transparent, public and open to all regardless of ethnicity, religion or gender;
- provide periodic training to enhance the skills and capacity of both employees and contractors;
- draw up procedures and management plans for all construction camps, in relation to contacts with local settlements;
- provide periodic training on liaison with local settlements to all staff employed by the BTC Co. Project and Contractors;
- establish a community investment programme that delivers mutual benefits to the BTC Co. and communities along the pipeline route;
- seek opportunities for communities to mutually benefit from the activities undertaken, and infrastructure required, by the Project.

The social mitigation measures have been grouped into six supporting social management plans that need to be taken forward in parallel by different parties within the Project and Contractor teams. For each of the plans, the Construction Contractor, BOTAŞ and the BTC Co. have been identified as having primary responsibility.

The plans required to implement the social impact mitigation measures identified during the EIA process are as follows:

- **Community Liaison Management Plan** outlining measures required to prevent negative impacts that could be caused by construction workers and construction camps and also measures required to ensure effective two-way communication with local settlements.

- **Construction Impacts Management Plan** outlining measures required to minimise impacts caused during construction of the facilities.

- **Community Safety Management Plan** outlining measures to ensure the safety of local communities. Many of these measures also appear in the other plans, but are brought together here to provide a focus for their management and monitoring.

- **Employment and Training Management Plan** outlining measures to maximise employment opportunities to project affected communities and the local regions through which the pipeline passes and in which the marine terminal is located.

- **Procurement and Supply Chain Management Plan** outlining measures to maximise opportunities to project affected communities and the local regions through which the pipeline passes to benefit from supply of goods and services required by the Project.

Monitoring Plans for the construction and operation of the pipeline, AGIs, construction camps and BTC Marine Terminal have also been compiled. These plans outline the monitoring actions, responsibilities and timing for key mitigation measures, as well as the targets against which performance will be assessed in each area.

In addition an Overview of Land Acquisition Process (OLAP) has been developed outlining measures require to minimise social or economic impacts arising from temporary or permanent resettlement of affected individuals. This Plan is currently in preparation; the OLAP is presented in Appendix C9.

17.2.6 Contractor management plans and procedures

The MMPs and supporting management plans are project wide plans that specify the standards and requirements applicable to all aspects of the BTC Pipeline Project in Turkey. The project itself is made up of a number of separate stages and components covering a variety of locations and activities. In addition, a number of different contractors will be responsible for the construction of the different aspects of the Project. In order to ensure both consistency in environmental and social performance and the successful application of the project wide standards and requirements in a variety of circumstances, all Contractors will be required to adopt and implement the requirements of the MMPs and supporting management plans as they pertain to the scope of their contract.

In order to achieve this, all Contractors will be required to submit project specific plans and procedures that demonstrate the means by which the commitments made in the EIA and the requirements of the MMPs and supporting project-wide management plans will be implemented in relation to their specific scope of work. Contractor plans and procedures will be reviewed and approved to ensure the requirements of the project-wide MMPs and supporting management plans will be fully met in a consistent manner throughout all aspects of the BTC Project.

17.2.7 Management during operation

The MMPs and supporting management plans are primarily aimed at the construction and commissioning phases of the Project. However, the standards and general requirements outlined in these documents will also apply throughout the operational phase of the Project.

Site-specific operational management plans and procedures will be developed during the design and construction phase of the Project in conjunction with the development of operational procedures. These operational management plans will ensure that all commitments made in the EIA relevant to the operational phase of the Project are fully implemented and monitored. The process of continual improvement will be implemented in accordance with the requirements of ISO 14001.

17.3 IMPLEMENTATION

17.3.1 Introduction

The following sections provide a brief overview of some of the key environmental and social management requirements that will be applied throughout the Project to ensure successful implementation of the various measures as defined in the MMPs and supporting management plans.

17.3.2 Responsibilities

BTC Co is fully committed to meeting the provisions of the EIA. As the Turnkey Contractor and Designated Operator of the BTC Project, BOTAŞ will have responsibility for all environmental planning, mitigation, management and monitoring in Turkey including delivery of all commitments made in this EIA Report and for the development and implementation of the various outline Management and Monitoring Plans presented in Appendix C to this EIA report to the satisfaction of BTC Owners and the Turkish regulators. BOTAŞ management will be responsible for the performance of all its Contractors and for ensuring that all EIA commitments are translated into Contractors requirements and that these requirements, are implemented to the full intent and extent of the original commitment.

Although these plans comprise a series of stand alone documents, the MMPs and supporting management plans will be fully integrated into the BTC Project Environmental Management System. This will ensure:

- ownership of the MMPs and supporting management plans at the highest level;
- appropriate resource allocation to the implementation of the provisions of the EMMP and supporting management plans;
- effective implementation and maintenance of the management control and monitoring systems that are defined by the MMPs and supporting management plans.

The Contractors will be responsible for the implementation of, and adherence to, all the mitigation measures outlined in the EIA, MMPs and supporting management plans. The Contractors and Sub-contractors will be required to adopt the provisions of the MMPs as if it they were their own and to demonstrate to the satisfaction of BOTAŞ that the commitments made in the EIA are being implemented.

17.3.3 Inspection, monitoring and audit

Inspection and monitoring of the environmental effects of construction and operational activities shall enable the effectiveness of environmental mitigation to be evaluated. It will also enable

any unresolved environmental and social problems to be highlighted and for effective solutions to be identified.

Both BOTAŞ and its Contractors shall be required to demonstrate how environmental requirements are being complied with. BOTAŞ will reassure itself that the Construction Contractor is complying with the requirements of the EIA, MMPs and supporting management plans through a programme of site inspections and, more formally constituted, audits by BOTAŞ' representatives. In addition, Contractors will be required to implement an ongoing programme of internal inspections and audits and maintain the full documentation required in the various management plans for independent validation.

The BOTAŞ Community Relations Team will monitor implementation of, and adherence to, the SMMP through liaison with the Construction Contractor and meetings with representatives of affected settlements. The BTC Co.'s Participants' Environmental and Social Relations Team will undertake a quality assurance role and will support BOTAŞ on identified monitoring actions.

In addition to the management structure established for the day-to-day overseeing of the Contractor's environmental and social performance, BOTAŞ will maintain an oversight and audit role for all aspects of the monitoring programme. This will include independent monitoring at selected sites throughout construction to verify the results of contractors monitoring programmes. In addition, compliance monitoring and inspection programmes will be undertaken by independent auditors (on behalf of the BTC Co.), the Turkish authorities, and international financial institutions (IFIs). Contractors will provide access to all sites and all necessary assistance to facilitate monitoring by BOTAŞ or any other approved organisation

17.3.4 Complaints procedure and resolution of problems

BOTAŞ, in coordination with its various contractors, will set up a complaints procedure that will enable any complaints to be made directly to a nominated individual. The complaint will be investigated by the Contractor's *Community Liaison Officer/s (CLO/s),* in coordination with BOTAŞ, and action will be taken as necessary.

All complaints will be recorded on site and the status of response actions will be recorded on a regular basis until corrective actions have been adequately implemented. BOTAŞ shall ensure that clear instructions are given to all Contractors and BOTAŞ personnel regarding the procedure to be followed when a complaint is received and the responsibilities for ensuring appropriate response action is undertaken. BOTAŞ shall ensure that residents living near to construction activities are kept informed of the Contractor's proposed working schedule and are advised of the expected time, duration and aims of the works by the Contractor.

Where problems are identified during inspection, monitoring, audit or due to a complaint, an appropriate course of action to remedy the situation will be agreed by the BOTAŞ Environmental Inspector and/or Community Relations Supervisor and the Construction Contractor. The Construction Contractor will be required to make adequate resources available to undertake corrective action immediately.

17.3.5 Training

BOTAŞ and its Contractors shall develop and implement an environmental management training programme. The training programme shall include initial induction training workshops for all site personnel and more specific training for those undertaking particular activities or tasks or for those with management responsibilities.

The training programme shall ensure that all site personnel:

- fully understand the management and monitoring requirements of the Project and how they shall be implemented on site;
- fully understand the environmental, social and cultural sensitivities of the areas within which the pipeline, marine terminal and other facilities shall be constructed;
- undergo health awareness training;
- fully understand the procedures for responding to the media, unauthorised visitors to the site and enquiries by the public;
- are fully aware of how to respond to unforeseen events and incidents; and
- are aware of the roles of the Contractor staff and the BOTAŞ representatives with respect to environmental and social issues.

17.3.6 Reporting and review

BOTAŞ shall develop and implement a programme of reporting throughout all stages of the BTC Project. Contractors will be required to fully comply with the reporting programme in terms of both timely submission of reports and an acceptable level of detail. It is envisaged that the reporting programme will include the following requirements:

- daily environmental checklist to be completed by all on-site environmental inspectors;
- daily reports detailing any community incidents causing injury or resulting in, or with the potential to result in, delays or a stoppage of the work;
- weekly environmental reports from all Contractors and on-site BOTAŞ environmental inspectors highlighting issues/problems during that week and the measure taken to address them;
- fortnightly reports detailing any disputes that have not been resolved within seven days, as well as a summary of the daily reports;
- monthly environmental compliance reports demonstrating compliance with all relevant requirements of the MMPs and EIA as they pertain to the Contractor's scope of work, highlighting areas of non-compliance and measures taken to address them; and
- monthly reports detailing community liaison activities carried out and any activities planned.

The reporting programme will form the basis for a programme of regular reviews of both Construction Contractor's and BOTAŞ' performance. These reviews will be used to identify areas and strategies for achieving improvements in environmental and social performance.

17.4 ENVIRONMENTAL AND SOCIAL INVESTMENT PROGRAMMES

17.4.1 Overview

The BTC Co. are in the process of developing discrete Environmental and Community Investment Programmes to augment the direct mitigation measures that they are committed to implement within the EIA process. These Investment Programmes and BOTAŞ Environmental and Social Investment Strategy are summarised in the sub sections that follow.

17.4.2 BTC Co's Environmental Investment Programme

17.4.2.1 Background

Whilst significant efforts have been taken to avoid areas of high biodiversity, largely through route selection and careful siting of above ground facilities, it is recognised that there are residual impacts on natural habitats. Direct mitigation measures aimed at the removal or reduction of adverse impacts on natural habitats or their functions will be implemented (detailed in Section 6). Reinstatement practices will also ensure that effects on natural habitats are minimised (Section 6 and the Reinstatement Plan). Furthermore, in line with BTC Company's policy, and to meet the requirements of the World Bank Group Policy on Natural Habitats (Operational Policy 4.04, June 2001), an Environmental Investment Programme (EIP) will be established. The aim of the EIP will be, where possible, to enhance biodiversity either directly in the area of potential impact, or indirectly through offsite projects.

17.4.2.2 Objectives of environmental investments

The primary focus of the EIP will be on Protected Areas (either designated or proposed) and protected species. In addition, areas of high ecological significance outside the protected areas system or other key species will be considered.

17.4.2.3 Investment principles

The EIP is in the process of development. This is being undertaken through consultation with stakeholders to gain an understanding of issues/areas of concern where input would be most valuable. The intention is that potential schemes are developed and implemented in conjunction with relevant stakeholder bodies and the identification of potential partners is underway.

The EIP will be implemented according to the following principles:

- It will take account of the requirements of IFIs and Corporate policies on effects on natural habitats.
- As a minimum, programmes will be aimed at addressing the 'no net loss' principle.
- Proposed schemes will take into account the views, roles and rights of groups, including NGOs and local communities. Consultation has been undertaken on mitigation options and further liaison will be completed to refine strategies.
- Government bodies, NGOs and, potentially, local communities will be involved in the implementation and monitoring of schemes. Monitoring and evaluation will allow assessment of the effectiveness of the scheme and permit refinement as necessary.

- As far as is feasible, proposed schemes will link with other project related investment programmes, in particular the Community Investment Programme. Such an integrated approach would facilitate the success and sustainability of the programmes.
- Schemes will be developed that take into account and balance the socio-economic needs of local communities and the need to protect and enhance biological diversity.
- In developing projects, every effort would be made to avoid duplicating the efforts of other international and local agencies or government departments; opportunities to leverage existing programmes and co-operate with existing organizations will be sought.
- Where applicable, programmes will take into consideration the biodiversity priorities of the Republic of Turkey.
- Clear targets and measurements of success for the Projects will be identified.
- It will be the responsibility of the BTC Company.

17.4.3 BTC Co's Community Investment Programme

17.4.3.1 Background

BTC Co. Corporate policy states that the company will generate "economic benefits and opportunities for an enhanced quality of life for those whom our business impacts,"[3]. To meet this goal, BP (represented by BTC Co.) has committed to designing and implementing a community investment programme in the areas most affected by the construction activities. The BTC Co.'s Community Investment Programme will go beyond the social impact mitigation measures described in Sections 6, 7, 12 and 13 of the EIA Report, and take a step further in order to meet the goal of having a positive influence in the areas in which BTC Co. operates.

17.4.3.2 Objective of community investment

The objective of the Community Investment Programme is to have a positive impact on communities most affected by construction activities by providing direct benefits, and by engaging with and adding value to local communities in a sustainable way.

17.4.3.3 Types of community investment

Currently BTC Co. intends to implement two types of community investment projects:

- **Local Community Projects:** these projects are relatively small in scale and duration but respond to an immediate felt need at the community level. These projects will take place in communities that are also directly affected by the construction activities. BTC Co. will take a phased approach to this and will first target those communities that will see activity during the early work programme within the impact area as defined in the EIA. This phased approach will enable BTC Co. to test the methodology and learn lessons as the programme proceeds. Ideas for potential projects will be based on consultation undertaken during the EIA process, which identified both household and settlement level needs. In addition, BP will consult with locally active NGOs to vet these potential ideas, gain from the experience of NGOs in the region, and identify potential NGO implementation partners.

[3] BP Business Policy "What We Stand For"

- **Sustainable Development Projects:** These projects will form the bulk of the Community Investment Programme. It is anticipated that they will be larger in scale and longer term in duration than the *'Local Community Projects'* and will aim to provide a sustainable development benefit. These projects will take place primarily in communities that are directly affected by pipeline activities, but may be extended to nearby towns or groups of settlements. Ideas for potential projects will be drawn from settlement-level consultations. This will require substantial discussion with active NGOs, international development agencies and government in order to ensure that BTC Co. is neither duplicating effort nor assuming the responsibilities of local or national authorities, but is adding value and/or filling needed gaps.

17.4.3.4 Criteria for community investment

The Community Investment Programme will apply criteria for the selection of both individual projects and partners for the implementation of projects. These criteria draw on international community/social investment best practice and local experience gathered through the implementation of the existing BP programmes in the country.

The criteria for the selection of programmes and projects will include the following:

- **Community needs based:** programmes and projects will be designed and implemented in consultation with communities and other stakeholders experienced in community investment and development in the country. The concerns identified in the EIA will provide the initial means for analysing community needs and priorities.
- **Impact:** programmes and projects should deliver material and measurable social and/or economic benefits to communities directly or indirectly affected by the Project.
- **Sustainability:** whether short-term or long-term in nature, programmes and projects should be designed to deliver lasting social and economic benefits as well as protect and enhance biological diversity.
- **Transparency:** programmes and projects must be transparent and be open to internal and external scrutiny of potential beneficiaries, NGOs and government departments to understand the approach.
- **Prevention of duplication:** in selecting projects, every effort will be made to avoid duplicating the efforts of other companies, international and local agencies or government departments; opportunities to leverage existing programmes and co-operate with existing organisations will be sought.
- **Measurement:** clear targets and measurements of success for the projects will be identified.
- **Best practice:** BTC Co. will aim to set its strategy and select programmes that are 'best practice' in community investment – recognising that this is a new and evolving practice in the region.
- **Local Participation:** programmes and projects should aim to encourage participation and contributions from local communities.
- **Local Implementation:** BTC Co. will encourage, as far as possible, the implementation of development projects by local NGOs etc.
- **Partnerships:** Programmes and projects should encourage the development of partnerships between BTC Co. and a wide range of organisations/civil society.

17.4.3.5 Timeframe for Community Investment Programme

To date, BTC Co. has developed a list of priority settlements and potential short-term projects and has consulted with Turkish NGOs to vet and refine this list. BTC Co. has also allocated appropriate budgets for the Community Investment Programme. The next step is to begin consultation in the priority settlements and to define partners for undertaking particular projects.

BTC Co. has also begun meetings with NGOs and donors in order to define longer-term sustainable development initiatives and identify suitable partners. It is expected that BTC Co. will refine this programme over the coming months. The Community Investment Programme will then be publicised in more detail later in 2002, once feedback on the EIA has been received and further consultation with authorities, NGOs and affected communities has taken place. It is expected that actual investments will begin later in 2002.

Implementation of the Community Investment Programme will follow standard business processes and control procedures for managing project performance and cost. BTC Co. will also ensure that its community liaison officers (CLOs) serve as a local focus to obtain community feedback as the Community Investment Programme progresses.

The Community Investment Programme will be publicised in more detail later in 2002, once feedback on the EIA has been received and further consultation with authorities, NGOs and affected communities has taken place. It is expected that actual investments will begin late in 2002.

17.4.4 BOTAŞ' Environmental and Social Investment Strategy

Respect for the environment, promoting safety of personnel and contributing towards community development are among the strategic aims identified by BOTAŞ General Management in the scope of their Integrated Management System. Within this context, afforestation programmes are planned for all BOTAŞ projects with the BTC Pipeline being the first of such projects planned. The programmes will be carried out in coordination with NGOs specialised in erosion control, soil protection and afforestation projects in Turkey.

With regard to the BTC Pipeline Project, it is planned that for each 250-300km of the BTC Pipeline, a 10ha area will be afforested in the provinces along the pipeline. Sites will be targeted with the aim of maximising access and amenity to the community.

17.5 NEXT STEPS

Following the formal approval of the EIA documentation, those designated as responsible for the implementation of measures management will:

- Review and integrate the relevant management and monitoring activities contained within the EMMP and the supporting management plans into existing management systems;
- Assign appropriate resources for implementation;
- Monitor implementation;
- Review the results of implementation to assess whether they have had a positive effect;
- Amend measures as necessary to meet objectives and contribute to key performance indicators.

18 OVERALL PROJECT ASSESSMENT

18.1 DEVELOPMENT OF THE PROJECT

The BTC Pipeline Project as currently proposed represents the results of several years of feasibility studies followed by 24 months of detailed assessment of a number of alternative technical and routing options to ascertain the preferred arrangement. These studies have included identification of environmental constraints, social concerns and geohazards along the route in order to assess potential risks to the integrity of the pipeline and to obtain relevant baseline data for pipeline design.

18.2 DEVELOPMENT OF THE EIA

18.2.1 The process that has been adopted

An Environmental Impact Assessment in line with current international practice has been undertaken for the Turkish section of the BTC Pipeline Project. The aim of the EIA process has been to ensure that all potential impacts on the physical, biological and human environment that are attributable to the Project are fully investigated, reported and, where necessary, managed.

This EIA has been undertaken and reported as an independent and objective process. In this regard, ERM has worked closely with ENVY, KORA METU, and Veri Arastirma, four specialist Turkish consultancies. Two other EIAs have been undertaken (by others) which assess impacts attributable to the Azerbaijan and Georgia sections of the Pipeline respectively.

In line with the relevant provisions of the Host Government Agreement (HGA), the approach adopted in this EIA is in accordance with World Bank guidelines (Article 8.42, Operational Policy OP 4.01) and EC Directive requirements (85/337/EEC, as amended by EC Directive 97/11/EC).

A feature of the process undertaken for this EIA has been the extent to which it has been underpinned by stakeholder engagement and public consultation. The focus of consultation has been to understand as far as possible how the Project will impact all stakeholders, and to obtain their ideas and opinions on management of impacts in order to influence project design, implementation and follow-up. In this regard, a Public Consultation and Disclosure Plan (PCDP) has established the framework for a structured and accountable programme of ongoing public engagement and participation that commenced in September 2001 and which is anticipated to continue throughout future Project development and implementation.

The EIA team has had the opportunity to work closely with the Detailed Engineering Design Team, with BOTAS and with BTC Co. with the common objective of fully assessing potential impacts and building mitigation into the Project's design.

The mitigation measures and procedures that have been developed as part of this EIA have been transcribed by the Project into Environmental and Social Specifications and together with the Management and Monitoring Plans, these will be included as contractual requirements in the Terms of Reference issued to bidders for the various construction contracts for the Project.

18.2.2 Challenges faced by the EIA process

In common with most Environmental Assessments, the EIA for the Turkish section of the BTC Pipeline Project has faced challenges in a number of areas in terms of the reliability of predicting impacts and in development of appropriate mitigation. These generally centre on the following factors.

- *Uncertainty due to gaps in knowledge of the baseline*. Where these difficulties have materialised, desk data has had to be relied upon as an interim measure and the EIA has as a result identified locations where pre-construction surveys and further data acquisition will be required.

- *Evolving Detailed Design*. Whilst an EIA is generally a process that parallels and interacts with design, it relies on design for certain data to facilitate identification of potential impacts. In a project of the scale and complexity of the proposed BTC Pipeline there are inevitably some outstanding issues that remain to be resolved in terms of the precise nature of project activities. The majority, if not all, of these are construction related and are, by implication, in most instances short-term. These are discussed further below.

  The EIA provides a level of assurance with regard to these impacts in terms of generic mitigation measures and professional judgement on the extent to which they can be mitigated. The measures are described in detail in the suite of Management and Monitoring Plans that are an integral part of the EIA Report.

- *Reliability of impact prediction and effectiveness of mitigation.* In recognition of the level of current uncertainty inherent in the findings, the EIA has stressed the importance of the Management and Monitoring Plans as vehicles for delivering appropriate and effective measures for managing, controlling and mitigating environmental and social impacts. In this regard, on the premise that the Management Plans will be rigorously implemented and enforced, the stated level of significance of identified impacts in this EIA where uncertainty exists, has been conservative (ie significance may be over-stated).

18.3 ISSUES ARISING OUT OF THE ENVIRONMENTAL ASSESSMENT

18.3.1 Issues that have been identified

The EIA has methodically undergone a process of identification of all potential impacts and assessment of their significance against a structured set of criteria that have been specifically developed for this project and which reflect current international practice. All residual impacts and benefits have been identified and summarised to assist decision makers in forming a view of the relative attributes of the Project. These are as follows:

Environmental	*Social*
Soils in certain sections of pipeline route	Unplanned disruption to infrastructure and service provision
Landscape in certain sections of pipeline route	Management of Employment Expectations
Landscape at Marine Terminal	Health risks
Water quality and abstraction	Safety of local residents and BTC workers
Biological environment at ESAs and other important sites	Social and cultural disturbance
Construction noise at certain settlements	Grievances over land compensation
Flare noise at Marine Terminal	Fishermen livelihoods
Archaeology	In-migration
Quarries and aggregates extraction	Impacts associated with PT1
Solid waste management	

18.3.2 Issues requiring finalisation

The EIA recognises that there are a number of activities, mainly construction related, which are not fully defined at this stage and which can only be resolved following selection of the various major Construction Contractors and detailed development of their work plans. These are summarised in Box 18.1.

Box 18.1 Issues Requiring Further Resolution

Waste Disposal

The quantities and types of waste that will be generated during construction and operation are subject to the construction methodology to be employed by the (yet to be selected) Construction Contractors and to ongoing detailed design and vendor selection for particular plant and machinery. The Project is committed to a waste management strategy that is based on minimisation of waste at source, identification of all waste arisings, maximising recycling and re-use, use only of licensed disposal sites with adequate capacity and inspection and audit to ensure compliance in line with Project specifications

Sourcing of Aggregates and other Construction Materials

The Project will require a significant quantity of aggregates, which have been quantified in this Report. The focus will be to minimise the level of transport of such materials by sourcing aggregates and other raw materials locally along the route. The Project is committed to the use of only licensed facilities with sufficient capacity. If new facilities are required to service Project needs, these will be subjected to the formal Turkish approvals process that includes a requirement for prior EIA approval.

Transport and Traffic

Construction of the Pipeline in particular will entail extensive numbers of traffic movements on public roads for the transport of materials and personnel to the pipeline RoW. The Project is committed to maximise the use of rail to minimise the level of increased traffic on public roads and to reinstate any directly attributable damage to public roads. The number of vehicle movements to transfer pipe and materials to the laydown areas has been approximated in this report, the strategy of which ports to use for the import of plant, equipment and materials (and hence the extent to which rail is used and the allocation of vehicle movements to particular road systems) is still subject to finalisation.

In recognition of the level of current uncertainty inherent in the findings, the EIA has stressed the importance of the Management and Monitoring Plans as the mechanism for delivering appropriate and effective measures for managing, controlling and mitigating the environmental and social impacts associated with these aspects of the Project. While this uncertainty has not affected the robustness and integrity of the EIA process, the potential for residual impacts remains pending the resolution of these issues. The implementation of the provisions of the Management and Monitoring Plans will be a key Contractor management requirement and will be informed by internal and external performance monitoring and audit.

18.3.3 Other key issues of the EIA

Protection of Biodiversity

Route selection has focussed on avoidance of environmentally sensitive areas and in this regard it has been successful in minimising impact in these areas. In a limited number of cases avoidance of protected areas has not been possible. For working in all environmentally sensitive areas (whether protected or not) a suite of protection measures has been proposed and has been accepted by the Project, including:

- avoidance of work within all environmentally sensitive areas during times of the year when sensitive habitats and/or species are most vulnerable;
- pre-clearance surveys by specialists prior to construction commencement of the presence of sensitive species: for example, rare species of bat (Schreiber's Long-Fingered Bat), grouse (Caucasian Black Grouse) and bears (Eurasian Brown Bear) during hibernation;
- narrowing of the working width (for example, in the Posof Wildlife Protection Area the working width will be decreased from the standard width of 28m to 8m in places);
- shortening the period that the spread is active in the sensitive area (from the normal duration of 2-4 months down to a target of 21 days in areas of high botanical value);
- adoption of detailed reinstatement measures defined in the Reinstatement Plan, which forms part of this EIA.

Furthermore, in line with BTC Owner's policy, and to meet the requirements of the World Bank Group Policy on Natural Habitats (Operational Policy 4.04, June 2001), an Environmental Investment Programme (EIP) will be established. The aim of the EIP will be, where possible, to enhance biodiversity either directly in the area of potential impact, or indirectly through offsite projects.

BOTAŞ' Environmental and Social Investment Strategy will be informed by the EIA with regard to the priority areas for enhancing biodiversity in the region, particularly in those areas most affected by the Project.

Greenhouse Gases (GHG)

The estimated total of GHG emissions from the BTC Project in Turkey in 2010, will represent 0.0016% contribution to global emissions. While the contribution of these emissions to global warming will be small, the Project has nevertheless sought to minimise GHG emissions. For example, combustion efficiency was a key factor in the selection of the pump drivers.

Assessment of Risk

The EIA has focussed considerable effort at assessing hazards presented by the Project. For example, an extensive Geohazards Study has been undertaken by a group of independent experts, thereby enabling the Project to take full account of geohazards in the design of the pipeline and associated facilities. Hazards have been assessed in terms of risk in the following studies:

- A *Pipeline Environmental Risk Assessment (ERA)* has enabled the design of the pipeline and the location of block valves to be optimised so as to minimise the risk of damage to the environment in the event of a pipeline leak.
- A *Marine ERA* has led to the identification of Yumurtalik Lagoons and turtles as highly sensitive Valuable Ecological Components.
- Oil spill modelling has enabled potential transboundary impacts associated with a range of oil spill scenarios to be assessed, again providing the basis for an appropriate response to be planned in cooperation with the national authorities.
- A Quantified Safety Risk Assessment of Pump Stations and BTC Marine Terminal has been undertaken to optimise safety aspects of the design.

These studies will be used in the development of the BTC Project Oil Spill Response Plan (OSRP).

Protection of Groundwater and Surface Water Resources

The EIA recognises the importance of protection of groundwater and surface water resources for the BTC Pipeline. The focus of the assessment has included the following:

- Input to construction planning with regard to construction discharges, water abstraction sustainability (particularly in regard to hydrotesting and camp supply), water quality issues at crossings or on unconfined aquifers/recharge zones.
- Input to design: for example, specialist studies to determine the appropriateness of licensed operational discharges and supply sustainability.
- A risk-based corrective action approach to dealing with contamination.
- An assessment of the adequacy of engineering measures designed to minimise, detect and respond to leaks along the pipeline route.
- Specification of a groundwater protection strategy which is focussed on delineating all sensitive aquifers along the route, understanding their dynamic characteristics and mapping this information on GIS so as to have a dynamic tool for informing oil spill response planning and execution.

Cumulative Impacts

The assessment of cumulative impacts has identified those areas where synergistic effects may arise from concurrent development. This applies particularly to the following.

- The Shah Deniz Project, particularly in those areas where the two projects will impact the same receptors such as at the Posof Wildlife Protection Area.
- The Gulf of Iskenderun where partial loss of access to fishing grounds (owing to imposition of exclusion zones around coastal facilities), general impacts on coastal

and marine ecological resources and deterioration of local air quality are all issues of potential concern.

The Project will endeavour to engage the other developers concerned, to work with them and the authorities, towards minimisation of the cumulative impacts identified.

Land Acquisition and Resettlement

The Project has developed a land acquisition process, which sets out the policies and principles to be applied in cases where project construction and operation activities will impact on land, other fixed assets, land-based and other livelihoods. This land acquisition process will form the basis of the Resettlement Action Plan (RAP), which is currently in the process of development in accordance with IFI requirements.

Cultural Heritage

The route has been subjected to desk study, archaeological field survey and to extensive consultation to identify all known and readily apparent cultural heritage features of importance. In the process, knowledge of cultural heritage issues along the route have been added to. In response to the findings of this work, the route alignment has sought to avoid these features. In the few areas where this has not been possible further investigations will be undertaken to minimise impacts as far as is practicable. However, the EIA recognises that during construction of the 1076km pipeline there is some probability of encountering artefacts or features of cultural importance. In this regard, the Cultural Heritage Management Plan, which forms part of this Report, provides the framework for identifying chance finds and how work should then proceed.

Employment Opportunities

The only one significant impact (considered highly likely) as a result of the Project is tension due to the limited number of employment opportunities. However, the Project has declared its commitment to working to manage this expectation through consistent and comprehensive communications by the community relations teams.

Sustainable Development

It is a feature of buried pipeline projects that they are, in the main, associated with predictable impacts during the construction phase and, provided reinstatement is properly applied, their long-term impacts are restricted to the above ground installations such as pump stations, valve stations and terminal facilities. Similarly, the direct benefits to affected settlements of such projects are mainly short-term employment during construction and significantly less extensive long-term employment during the operation phase. BTC Co. and BOTAŞ are committed to contribute to the long-term sustainability of Project affected settlements via their Environmental & Community Investment Programmes. The focus and direction of these investment programmes is currently under development.

18.4 THE PROJECT ASSESSMENT STATEMENT

The EIA has systematically and comprehensively examined all identified aspects of the Project with the potential to give rise to environmental or social impacts.

There are a number of residual impacts relating to construction of the pipeline and operation of the AGIs and Marine Terminal. However, by careful management (and in certain cases further studies to remove or reduce current uncertainty regarding their sensitivity) and the implementation of the various mitigation measures set out in this Report, these residual impacts will be managed.

On a national scale the BTC pipeline will bring significant financial benefits to Turkey. There are also a number of anticipated direct benefits for local settlements, particularly during the construction period, in terms of short and (in fewer cases) long-term employment. Community and environmental investment programmes will also benefit certain impacted communities.
